ABSTRACT

The effective integration of generative artificial intelligence in education is a fundamental aspect to prepare future generations. This study proposes an accelerated learning methodology in artificial intelligence, focused on its generative capacity, as a way to achieve this goal. It recognizes the challenge of getting teachers to engage with new technologies and adapt their methods in all subjects, not just those related to AI. This methodology not only promotes interest in science, technology, engineering and mathematics, but also facilitates student understanding of the ethical uses and risks associated with AI. Students' perceptions of generative AI are examined, addressing their emotions towards its evolution, evaluation of its ethical implications, and everyday use of AI tools. In addition, AI applications commonly used by students and their integration into other disciplines are investigated. The study aims to provide educators with a deeper understanding of students' perceptions of AI and its relevance in society and in their future career paths.

1. Introduction

Education has undergone significant transformation in recent decades, largely driven by technological advancements. In this context, artificial intelligence (AI) has emerged as a promising tool with the potential to revolutionize teaching and learning methods (Zaman, 2023; Huang, Saleh and Liu, 2021). As AI continues to evolve and become increasingly integrated into society, there is a growing need to educate the next generation about its capabilities, ethical implications, and potential for both innovation and misuse. One of the most innovative areas within AI is the so-called *generative AI*, which refers to systems capable of creating new and original content. These systems can generate texts with large language models (LLMs) (Achiam, Adler, Agarwal, Ahmad, Akkaya, Aleman, Almeida, Altschmidt, Altman, Anadkat et al., 2023; Touvron, Martin, Stone, Albert, Almahairi, Babaei, Bashlykov, Batra, Bhargava, Bhosale et al., 2023; Team, Anil, Borgeaud, Wu, Alayrac, Yu, Soricut, Schalkwyk, Dai, Hauth et al., 2023), images using diffusion models, generative adversarial networks (GANs) or variational autoencoders (VAEs) (Salimans, Goodfellow, Zaremba, Cheung, Radford and Chen, 2016; Borji, 2022), music by using wavenet or other transformers architectures (Dong, Hsiao, Yang and Yang, 2018; Briot, Hadjeres and Pachet, 2017; Wang, Zhao, Liu, Pang, Qin and Wu, 2024) and other types of data that can be used in a variety of applications.

The application of AI in education offers unique opportunities to personalize learning, adapting to the individual needs of each student (Pesovski, Santos, Henriques and Trajkovik, 2024), so they are systems that prioritize human needs, values and experiences, in this case of students and teachers. Different studies have been conducted to bring AI closer to educational centres at different levels and workflows (Holmes and Tuomi, 2022; Baidoo-Anu and Ansah, 2023; Lim, Gunasekara, Pallant, Pallant and Pechenkina, 2023; Chiu, 2023; Alasadi and Baiz, 2023; Sharples, 2023; Ruiz-Rojas, Acosta-Vargas, De-Moreta-Llovet and Gonzalez-Rodriguez, 2023; Mørch and Andersen, 2023; Yang, Ogata, Matsui and Chen, 2021; Yang, Ogata and Matsui, 2023; Cao, Tan, Gao, Xu, Chen, Heng and Li, 2024; Ruiz-Rojas et al., 2023). In addition, it allows educators to create interactive and dynamic educational materials that can increase student participation and engagement. However, effectively integrating generative AI into the classroom presents significant challenges, both technical and ethical (Alasadi and Baiz, 2023).

However, introducing AI concepts to students with no prior knowledge can be a complex task, which would require a lot of time and resources. Additionally, the teaching staff will need to be prepared to adapt the content of their classes with AI techniques, which is an even greater challenge (Liua, Salehb and Huang, 2021). In particular, this research aims to address this challenge by presenting a novel methodology tailored to introduce students to the world of AI-generated videos in an intensive session. In this way, students not only gain hands-on experience in AI creation but also develop a fundamental understanding of the risks and liabilities associated with AI technologies. In addition, this approach is designed to spark interest and curiosity, encouraging students to consider pursuing careers

in AI-related fields (Zastudil, Rogalska, Kapp, Vaughn and MacNeil, 2023; Tossell, Tenhundfeld, Momen, Cooley and de Visser, 2024; Ngo, 2023; Vallis, Wilson, Gozman and Buchanan, 2023; Leiker, Gyllen, Eldesouky and Cukurova, 2023; Țală, Müller, Năstase, Gheorghe et al., 2024; Su and Yang, 2023; Vartiainen and Tedre, 2023).

The motivation for this work is based on several fundamental objectives to advance the integration of artificial intelligence in education, and more specifically in its generative aspect. It introduces a novel AI rapid learning methodology that allows students to face first-hand the challenges and capabilities of these technologies. This hands-on experience serves to stimulate interest in science, technology, engineering and mathematics, the so-called STEM careers, and facilitates a deeper understanding of the practical applications of AI in various fields. In addition, this research explores how our methodology fosters collaboration between students from different schools and educational levels. By participating in collaborative AI projects, it has been observed that students who do not know each other collaborate to solve problems, exchange knowledge, and mutually enhance each other's educational experiences. Therefore, the methodology proposed in this article develops collaborative competency among students (Magraner and Valero, 2016).

A key aspect of this work is to investigate students' perceptions of generative AI following their participation in these experiential learning activities. Understanding high school students' attitudes, concerns, and opinions toward generative AI can provide valuable information about its potential impact on their academic and career paths. For educators, this study aims to demonstrate the pedagogical utility of generative AI (Karras, Holynski, Wang and Kemelmacher-Shlizerman, 2023; Khachatryan, Movsisyan, Tadevosyan, Henschel, Wang, Navasardyan and Shi, 2023; Gozalo-Brizuela and Garrido-Merchan, 2023; Karaarslan and Aydın, 2024; Wu, Ge, Wang, Lei, Gu, Shi, Hsu, Shan, Qie and Shou, 2023; Ali, Ravi, Williams, DiPaola and Breazeal, 2024; Han and Cai, 2023). Teachers can leverage this technology to design engaging learning activities that encourage students to explore deeper into other subjects more deeply and creatively, often without them even realizing it. In addition, this research aims to identify the AI applications commonly used by students in their daily lives and to understand the purposes for which they are used. This exploration offers insight into the current integration of AI technology into students' routines and highlights potential areas for further application and improvement. As the exploration progresses, four key *research questions* (RQ) guide this inquiry:

- **RQ1.** What emotions do students experience when they think about the evolution of AI and how do they evaluate the ethical implications and responsibilities of using AI tools in their learning?
- **RQ2.** Can the use of generative AI foster creativity and innovation in students?

- **RQ3.** Do teachers currently encourage the use of AI as a resource to support lectures or assignments?
- **RQ4.** Can the use of generative AI help with learning in other disciplines?

These questions address some psychological dimensions of AI integration in education —emotional, creative, and practical, from the learner's perspective. By exploring these questions, a better understanding of learners' perceptions and emotions regarding AI, its developments, and its potential applications is aimed to be provided to educators. In addition, the aim is to deepen the understanding of the role of AI in society and its impact on the professions of the future. Therefore, two main lines of research are pursued in this work. The first one focuses on the methodology of accelerated learning. On the other hand, the analysis aims to understand students' perceptions of AI: how it is used, the possible uses attributed to it, and how they integrate it into their daily lives as a support tool rather than as a definitive solution. Students are aware of the limitations of AI and the need to use it with caution and appropriate knowledge. Furthermore, this study aims to elicit reflections among students and to understand how they see the future of AI and the implications of its evolution.

In the next section 2, the methodological part of fast AI learning is explained. Also in this section, the dynamics of the questions are explained. Subsequently, in section 3, the experiment, the activity and the results by question type are explained to give a better view of the results. After analyzing the results, the research questions initially posed are addressed in section 4. Finally, the main conclusions of this study and implications for future work are presented in section 5.

2. Methodological framework and information retrieval

It is presented a detailed proposal to teach artificial intelligence to middle and high school students, focusing on its ethical uses and practical applications in their daily lives. This educational program is structured in two main segments to ensure a deep and thoughtful understanding of the subject. In the first part, the basics of AI are addressed, starting with the definition of human intelligence. This section is designed to be formative and dynamic, lasting approximately one hour. During this initial session, strategic questions are posed to students to encourage reflection on the concept of AI and its roots in human intelligence. They are asked what they understand by *intelligence*. Student responses included concepts such as "*ability to solve problems, analyze, reason, innovate, knowledge, logic and critical reasoning, think*". After capturing the students' attention and initiating an active dialogue with them, exploration of the concept of artificial intelligence commenced. Despite being a term widely used in today's society, it is observed that it has not been analyzed in depth in its close context. The students' answers to the question of what they understood by artificial

Figure 1: Scheme of explanation of the learning of an algorithm included in the methodology.

intelligence included descriptions such as “*problem-solving machine, imitating human intelligence, improvement of human intelligence, the ability of non-living beings to solve problems, non-human being with the intention of copying us*”. It is remarkable how many students perceive artificial intelligence as a tool intended to enhance human capability.

After this introduction, a more detailed analysis of AI is made, focusing on the different learning methods used by AI systems. To make the content more accessible and relevant to students with ages within the interval [15-17], analogies are made between how AI-models learn and their day-to-day lives. A brief introduction to AI is given, explaining its learning methods. To arouse their interest and facilitate their understanding of the topics, it is suggested that when studying for an exam, they act as AI models. They will prepare to learn the subject and to pass the exam by studying the contents found in the study books for further evaluation. If they pass the teacher’s assessment, as shown in Figure 1, they will have efficiently taken advantage of the training and it will be considered completed. However, if they do not reach the minimum score set by the teacher, it will be necessary to study more for the next exam to re-evaluate the knowledge acquired.

Explanation of algorithms at a basic level, giving examples from your daily life in which a model such as an autonomous car may be involved. In addition, several end-to-end generative AI applications are presented so that they can feel that it is close and very accessible. One of these applications is Doodle-dash. This application recognizes and interprets the doodles drawn by students ((Wolf, Debut, Sanh, Chaumond, Delangue, Moi, Cistac, Rault, Louf, Funtowicz et al., 2019)). In an educational context it helps students improve their creativity, critical thinking and artistic development. On the other hand, it is presented the application AutoDraw, which uses recurrent neural networks (RNNs) to recognize doodles drawn and then complete them in an accurate way, being useful to help artistic expression with reduced mobility or *neurodegenerative* disorders such as Alzheimer’s and Parkinson’s disease (Gan and Khoo, 2024), becoming a tool for *democratization of art* (Ha and Eck, 2017). It also explains Smart Cuisine as an application to design recipes, following nutrition and culinary science. The goal of this type of program is to learn important skills such as cooking and nutrition, as well as to help a smart use of resources in the kitchen, being a very valuable tool for sustainable cooking, as it can give you recipes with only

the ingredients you already have, helping the user to save and intelligently reuse ingredients (Kansaksiri, Panomkhet and Tantisuwichwong, 2023). This tool is explained to give students an understanding of the great interaction that generative AI can have with other fields. After explaining in a simple way the principles of AI as well as practical approaches that can be used by students as a tool, a short free-response survey with the following two questions is asked to get their opinion:

- What tools have you used and what for? (See No. 24 in Table 3)
- In what situations in your day-to-day school life could you use AI? (See No. 25 in Table 3)

From these free-response questions, different answers of forms of use by each student emerged, although they had several in common. In Figure 2 it can be seen the *Wordcloud* with the most frequent words in the answers for both questions 24 and 25 respectively. As can be seen, the most used tools include ChatGPT for text generation, Copilot (Perez, Dedden and Goodloe, 2020) and Dall-e as an image generator based on transformers (Vaswani, Shazeer, Parmar, Uszkoreit, Jones, Gomez, Kaiser and Polosukhin, 2017). Other tools also include Chatbots and several programs for creating presentations and obtaining recommendations. When asked what they used them for, they answered that they used them to solve problems faster, compare and check information and rewrite results obtained by other AI tools to humanize the results. Interestingly, one finding is that some students use tools such as ChatGPT in times of boredom to talk, indicating some emotional interaction with the platforms (Bartsch and Viehoff, 2010; Tan, 2008). On the other hand, students were asked to think about possible uses they could make of AI in their daily lives. In Figure 2, it is found that most of them would use it for their daily homework, although there are other interesting uses such as checking their work, generating logos, getting information faster, getting inspired with new ideas, finding shortcuts, etc., which allows students to improve and achieve results more efficiently. Some students indicated that they used these applications to generate questions to help them study, a clear example of the use of AI as a tool to support the study of other subjects.

This was followed by an interactive activity in which all students actively participated. They used artificial intelligence tools to create videos from free prompts, using notebooks that employ stable diffusion models (Patreon, 2022). To assess the students’ perception of this experience, a survey was conducted that addressed several dimensions, both sociological and psychological. The objective was to understand how the integration of artificial intelligence in the classroom can influence students’ attitudes, learning and behavior.

The survey questions are structured in six distinct analytical dimensions, each focusing on different aspects of the use of artificial intelligence in education. This multidimensional

approaches written in the prompts, the so-called *prompt engineering* (White, Fu, Hays, Sandborn, Olea, Gilbert, Elnashar, Spencer-Smith and Schmidt, 2023), and to favor interaction and collaboration among the students:

1. Evolution of civilizations.
2. Fractals.
3. Cities as different artist styles.
4. Evolution of clothing.

All groups made 100 frames so that the changes in the prompts could be seen, but they were limited by the time of the session. Two hours were left for the activity, during that time the students showed high participation and collaboration, improving the prompts by sharing various aspects or bad results as described. The students checked how parameters such as zoom or angle could affect the final results. All of them used 2D animations and a frequency of 4 seconds of video per 50 frames generated. Eight-second videos were generated at a rate of 12 frames per second, i.e. approximately 100 frames per video in total. Each video consisted of five successive prompts, as shown in Figure 4, of twenty frames each. While making the videos, the students realized that sometimes they did not get the results they expected from the AI, so they used *negative prompts* with the same frame rate to better guide the generative model and get more accurate results from, in this case, *deformable stable diffusion* (Patreon, 2022) which is an open source software and provides significantly better results than other non-diffusion based models such as generative adversarial networks (GANs) (Dhariwal and Nichol, 2021).

Each working group was composed by two students. Within the global themes, students are given the freedom to write the prompts, which encourages creativity and innovation of the outputs. Note that although there are similar elements because the themes were bounded, there are many elements that differ as can be seen in Figures 4a,b,c. During this activity, some students detected the presence of bias in artificial intelligence, which led to an enriching ethical debate. Through a historical example observed in the first frames of Figure 4g, it was discussed how in the 1920s, the AI did not recognize the possibility of black people belonging to higher socioeconomic classes in American society. However, in stills from the 2000s, a significant change is observed in the same figure, where AI is already able to recognize and anticipate without difficulty the existence of families composed of black women and white men in the upper classes. This progress reflects how AI has adapted to the evolution of racial integration in contemporary society. Although there is still work to be done, it is clear that AI systems are moving toward more ethical and less discriminatory practices, in line with social evolution. Students understood that the data on which these AI models are trained are generated by humans, which highlights the importance of being meticulous and ethical in their selection and handling. Understanding these aspects is not only a fundamental part of learning, but also key to fostering inclusive, equitable and

quality education, in line with the United Nations *Sustainable Development Goal* (SDG) number 4: *quality education*, (Ferguson and Roofe, 2020; Sdg, 2019).

Next, the answers to the questionnaire made by the students at the end of the activity will be analyzed in detail. This survey has questions of different categories, so they will be analyzed separately, although an overall conclusion will be given at the end of the activity.

3.1. Binary questions analysis

The proposed binary questions aim to understand the level of training of students from different schools regarding the ethical uses of artificial intelligence, as well as to investigate whether teachers encourage its integration into their teaching methods.

In question 17, 60% of students reported that they have received training on the ethical use of AI as can be seen in Figure 5. However, a striking contrast is evident from the responses to question 16, where only 10% of students reported that their teachers actively promote or facilitate the use of AI in their academic pursuits. This disparity highlights a potential area for professional development among educators. There is a notable opportunity to enhance teacher training, focusing on the integration and pedagogical applications of AI across various disciplines. Additionally, it was observed that students frequently turned to online resources to gather more detailed information on subjects such as history or art to better tailor their AI-driven prompts. This behavior suggests an enhancement in students' research and academic study skills facilitated by the utilization of AI technologies. The proactive use of AI in educational settings appears to contribute positively to the interdisciplinary research capabilities of students (Kamposiori, Warwick and Mahony, 2022). In question 15, a significant majority (90%) of the students responded negatively to the idea of entrusting their activities to artificial intelligence. The subsequent question, question 22, sought to elucidate the reasons behind their reluctance. Analysis of the responses reveals frequent use of the words *mistake* and *help*. Some students' explanations are:

- "You never know if the AI can make a mistake. After all, it is a replica of us, and we make mistakes. They might make fewer mistakes, but they can still make them."
- "Even though it has performed well, there have been instances when it did not think the same way I did."
- "Not entirely reliable."
- "May be flawed."
- "To help me but not to do everything"

Only the 10% of the students indicated that they would leave their activities in the hands of AI focused on AI's capabilities to help human beings, "Because it seems to me that it is very well qualified to help human beings."

Figure 4: Videos produced by students' free prompts. a) A man in egypt with pyramids in the background, a man in the ancient greece, a roman emperor during the fall of roman empire, a native american being colonized, a french republican during french revolution. b) Primitive man and women in a cavern, man and women of the roman empire, man and women archer in a castle, mustketeer and a woman musketeer in the medium age, man and women in the wall street of new york. c) a prehistorical landscape with a bunch of dinosaurs trending on artstation, four pyramids in the desert with a sunny sky, the roman colosseum with a gladiator fighting against a lion, an historical castle with a rtmuch under a storm, a city of Dubai in a sunny day with their skyscrapers. d) a beautiful city with Velazquez style, a beautiful city with Picasso style. e) Fractals, vivid colors. f) a beautiful boy dressed like 1920s style, a beautiful boy dressed like 1940s style, a beautiful boy dressed like 1960s style, a beautiful boy dressed like a rock style, a beautiful boy dressed with sport clothes. g) Man and a woman dressed like in the 1920s, Man and a woman dressed like in the 1940s, Man and a woman dressed like in the 1960s, Man and a woman dressed like in the 1980s, Man and a woman dressed like in the 2000s.

Figure 5: Binary responses.

Overall, these comments reflect a general concern about the potential for errors and a lack of complete reliability in AI systems, influencing the students' trust in such technologies for managing their activities.

3.2. Likert scale questions analysis

Once the students' responses to the Likert scale questions were collected, it is proceeded to their analysis using descriptive statistics. The results obtained are shown in Table 4. Likewise, Figure 6 shows the study of correlations between the questions in Table 1 belonging to the dimensions LPE, IM, CPI, EE and FOP to better understand how they relate to each other and to understand student behaviors. In this analysis, special attention is paid to correlations whose values, positive or negative, exceed the threshold of 0.75, since this indicates a strong association between the questions analyzed. Note that question 14 is not included in the correlation matrix since it does not provide useful information on the relationships between the variables, since as can be seen in Table 4, $\sigma_{14} = 0$, there being no dispersion in the sample responses.

Analysis of the survey responses reveals that active class participation is closely linked to several positive outcomes in student learning and motivation concerning AI. First, there is a high correlation (0.88) between active participation (question 1 from Table 1) and learning how different technologies can collaborate to generate innovative results (question 4 from Table 1). The proposed methodology encourages students' active participation ($\mu_1 = 4.8$), thus enhancing AI learning through collaboration between technologies ($\mu_4 = 4.4$). Moreover, this active participation that promotes this methodology favours significantly the students' motivation to explore AI-related topics outside the school setting ($\mu_{10} = 4.1$). Finally, active participation also has a significantly high correlation with the interaction of AI tools (question 6 from Table 1) as an interesting experience within the classroom ($\mu_6 = 4.5$) and with overall satisfaction with the proposed methodology (question 13 from Table 1, $\mu_{13} = 4.7$).

The high correlation (0.83) between question 7 and question 12 from Table 1 indicates that increased student

Table 4

Descriptive statistics of Likert scale evaluated questions, where three is the Neutral status and $n = 10$.

ID Question	μ	Mode	σ	Wilcoxon
1	4.8	5	0.421	0.00195
2	4.6	5	0.516	0.00195
3	4.7	5	0.483	0.00195
4	4.4	5	0.843	0.00829
5	4.3	4	0.674	0.00617
6	4.5	5	0.707	0.00575
7	4.5	5	0.849	0.00665
8	4.0	4	0.816	0.01518
9	1.8	1	0.918	0.01387
10	4.1	4	0.994	0.01762
11	4.5	4	0.527	0.00195
12	4.0	4	0.942	0.01969
13	4.7	5	0.483	0.00195
14	5.0	5	0.000	-

interest in exploring AI-related topics after participating in the learning methodology is strongly associated with increased interest in exploring technology-related careers in the future. This suggests that the classroom experience is not only sparking increased interest in the AI subject itself ($\mu_7 = 4.5$), but is also inspiring students to consider career options within the technology field ($\mu_{12} = 4.0$). This finding is significant as it indicates the potential positive impact that AI learning methodology can have in shaping students' future career paths. Apart from that, the high correlation (0.95) between students' interest in AI-related topics (question 7 from Table 1) and satisfaction with the learning methodology used (question 13 from Table 1) suggests that students' satisfaction favors their curiosity to learn more about AI. As student satisfaction is very high ($\mu_{13} = 4.7$), it shows that this methodology favors students' interest in AI topics.

On the other hand, a notable observation emerges when examining the high correlation between questions 6 and 8, indicating that an experience perceived as interesting and enriching with AI tools in class is strongly associated with an increase in students' confidence in using these technologies.

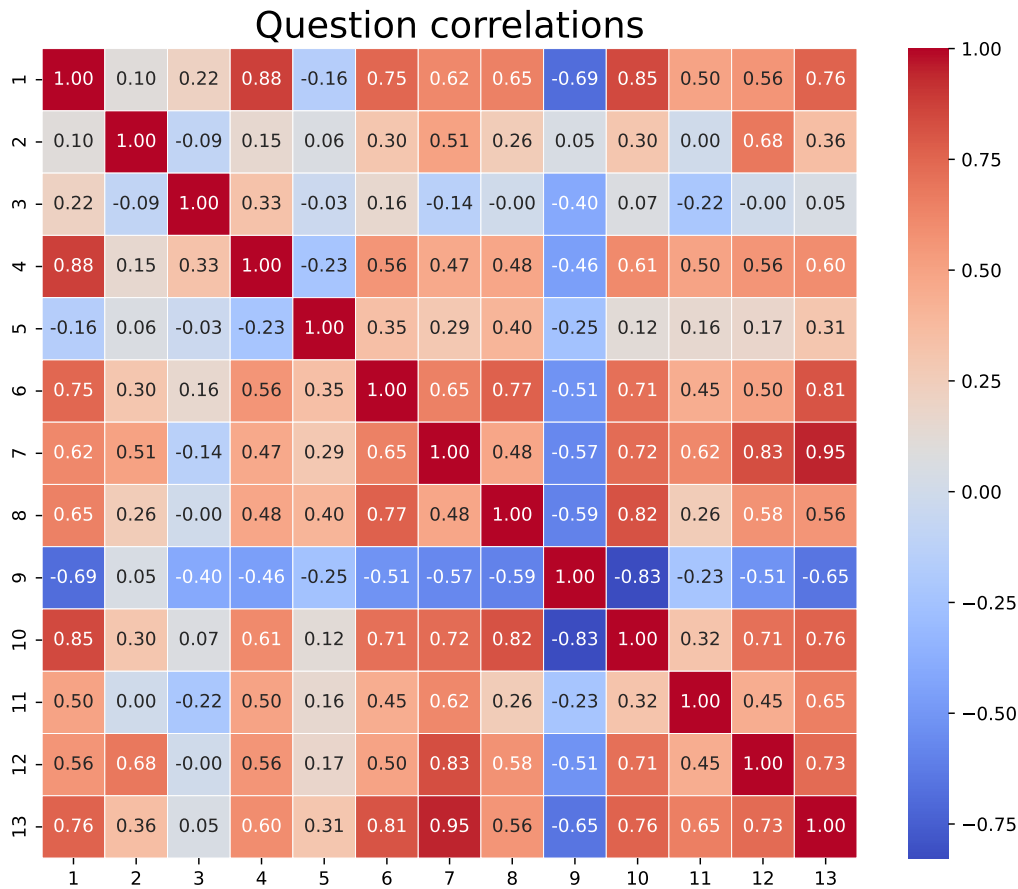

Figure 6: Correlation matrix among the Likert scale questions.

In the proposed methodology, students perceive that interaction with AI tools is positive and beneficial to their learning ($\mu_6 = 4.5$), so they also feel more confident and competent when using these technologies ($\mu_8 = 4.0$). Furthermore, the correlation of 0.81 between question 6 and question 13 reveals that a positive and enriching experience with the interaction of AI tools in class is closely linked to a higher overall satisfaction with the AI learning methodology. In this methodology, as students rate their experience with AI tools highly, they also have a very positive and satisfying perception ($\mu_{13} = 4.7$) of how the subject is taught in the classroom.

Question 10 has a notable positive correlation with question 8 (0.82) and with question 13 (0.76). This means that increased student motivation to learn about AI-related topics outside the school environment, as reflected in question 10, is highly correlated with both a greater feeling of safety in using AI technologies, as indicated by question 8, and greater overall satisfaction with the AI learning methodology and its applications in the classroom, as reflected in question 13.

These high correlations suggest that when students show greater interest and motivation to explore AI outside the classroom due to the learning methodology used, they also tend to feel more confident in using these technologies and are more satisfied with the way they are taught the subject matter in the classroom. This finding is significant because it suggests that the AI learning methodology is not only succeeding in increasing students' motivation to learn about the subject ($\mu_{10} = 4.1$), but it is also positively impacting their confidence ($\mu_8 = 4.0$) and satisfaction ($\mu_{13} = 4.7$) regarding how the subject is taught in the classroom. On the other hand, question 10 has a high negative correlation with question 9. This indicates that as students' perception of frustration decreases during their participation in the AI learning methodology (question 9 from Table 1), their motivation to learn about AI-related topics outside the school environment increases (question 10 from Table 1). This methodology favors that frustration is very low ($\mu_9 = 1.8$), and, therefore, that motivation to inquire about AI is high ($\mu_{10} = 4.1$). Finally, note that the value three on the

Likert scale reflects a neutral opinion. The students never responded to this option when answering the questionnaire, as is often the case in many studies, in which participants simply chose the intermediate option to not participate or to respond quickly.

This analysis of correlations and dimensions relies on the Wilcoxon test (Wiedermann and von Eye, 2013) to evaluate the significance of responses with respect to the neutral value on Likert scales. This non-parametric test is suitable for ordinal data and does not require assumptions of normality, being useful even in small samples. The results of the Wilcoxon test are presented in Table 4. The findings indicate very low *p-values* for all questions, suggesting significant differences between the responses and the neutral value of the Likert scale. This discrepancy highlights a trend where responses tend to be polarized rather than neutral, implying that students have displayed attitudes that are not passive or neutral, but rather demonstrate satisfaction with the evaluated methodology. It is important to note that question 14 lacks a *p-value* due to zero variability in the responses ($\sigma_{14} = 0$), meaning all responses were identical and therefore not suitable for significance testing. This uniformity in responses eliminates the possibility of conducting a meaningful statistical analysis for this particular question, but in itself as all responses were 5/5 on the Likert scale it can be concluded that all students recommend this methodology.

3.3. Free responses analysis

Next, a deeper analysis of the free responses provided by the students in the questionnaire will be conducted. The main objective is to gain a deeper understanding of their opinions, perceptions and experiences related to the methodology and the proposed activities. The specific questions to be addressed in this analysis are detailed in Table 3. These questions were designed to capture the direct impressions of the students, allowing them to freely express their thoughts and feelings about the activity and their experience with artificial intelligence. To facilitate understanding and visualization of the most recurring themes and words in the students' responses, word-clouds are created as shown in Figure 7. These word-clouds highlight the most frequently used words, providing a visual representation that helps to quickly identify the main themes and predominant opinions among students. Analysis of the free responses and word-clouds will provide us with a more complete and nuanced view of student perceptions. They will allow us to identify patterns, trends, and areas of interest or concern, which in turn will help us better understand how students perceive and value the methodology and their interaction with artificial intelligence.

When analyzing question 9, which addresses the frustration experienced during the activity, it is observed that the mean is 1.8, with the mode being 1. This suggests that most students felt actively engaged in the activity and did not experience a great deal of frustration. On the other hand, question 18 focused on understanding the reasons behind any frustration or confusion students may have felt. This question

was only answered if students expressed feeling frustrated or lost during the activity. Most indicated that their frustration was due to the AI interpreting the prompts in a different way than they had thought. A representative response was: *"Because I told the AI one thing and it interprets it differently from me."* This response suggests that the trainee experiences a sense of doubt regarding the AI, questioning whether the AI is always right. This discrepancy in interpretation may influence the students's perception of the AI's accuracy and reliability, or lead to a decrease in the trainee's confidence in his or her abilities, perceiving that his or her understanding or presentation of information does not match the level of accuracy or objectivity possessed by the AI (Singh, 2023; Famaye, Adisa and Irgens, 2023).

These results point to a key understanding on the part of the learners: what they understand and communicate does not necessarily match what the AI models understand. This is also due to the lack of interpretability of models. This discrepancy in interpretation between learners and AI highlights the importance of being careful and clear in explanations and communications with AI. Students need to understand that machines interpret information differently than humans and that it is necessary to be precise and detailed in instructions and explanations. This learning can be a valuable lesson for students, not only in the context of the specific activity but also in their future interaction with AI technology.

Question 19 focuses on how the applied methodology has contributed to enhancing students' creativity. The responses show a positive response and reveal several dimensions in which the methodology has had an impact on students' creativity. First, students indicate that the methodology has allowed them to think more openly and with a greater number of ideas *"Thinking in a more open way and with more ideas"*, suggesting that it fosters divergent thinking, in which multiple perspectives are explored, which is fundamental to creativity. In addition, students mention the *"infinite amount of possibilities"* that can be achieved with the use of AI. It gives them a wide range of options to explore and experiment with, enhancing their creativity by not limiting them to a single solution or approach. An interesting aspect is that, although the AI generates the content, learners feel responsible for thinking about what they want the AI to accomplish *"Even though the AI generates everything for you, you are the one who thinks about what you want the AI to do."* This perception reflects a human-machine collaboration, in which the participant guides and personalizes content production, which could contribute to their sense of authorship and creativity. In addition, the methodology has inspired learners to investigate previously unknown topics to improve their prompts, seeking information from other sources and feeling ambitious to explore them. This suggests that the methodology not only enhances creativity but also promotes self-directed learning and intellectual curiosity, underscoring the positive impact of the methodology on student learning. Interestingly, the use of these technologies makes students have to do more research on the topics to

about the potential risks and challenges associated with AI. There is a sense of unease and caution about the limits and possible negative consequences. Responses such as “*I am a bit worried that it will get out of control*”, “*I am interested but it can be dangerous*”, “*It is a double-edged sword and I worry that it will create more problems than it solves*”, reflect this perception of AI as a tool, with potential for both good and evil depending on how it is used “*Well, but you have to be careful in who uses it or how they use it*”. As can be seen in Figure 7, the most frequent words in the responses are *motivated* and aspects of concern such as *worry*, *worried* or *destroy*.

After conducting a thorough analysis of the numerical and free responses provided in our survey, the initial questions posed at the beginning of this study can now be addressed. These questions will be answered using the findings and data obtained, enabling us to provide an informed and detailed assessment of the issues investigated.

4. Research questions discussion

In this section, the findings obtained are discussed to answer the initial research questions, with a focus on students’ perceptions of the integration and impact of artificial intelligence in education. The answers provided by students offer us valuable insight into their emotions, attitudes and experiences related to the evolution of AI, its potential to foster creativity, the attitude of teachers towards its use, and its ability to enrich learning in different disciplines. Through this analysis, a better understanding of how students perceive and value AI as an educational tool is sought, identifying opportunities and challenges in its integration in the educational setting.

4.1. RQ1. What emotions do students experience when they think about the evolution of AI and how do they evaluate the ethical implications and responsibilities of using AI tools in their learning?

When considering the evolution of artificial intelligence, students experience a range of diversified emotions. On the one hand, many are excited and motivated by the transformative potential of AI, seeing opportunities for innovation and advancement in a variety of fields, including education. This optimistic outlook reflects an openness to the possibilities that AI can offer in terms of improving teaching, facilitating learning and personalizing education. On the other hand, not all students share a completely positive view. There are feelings of caution and concern regarding the potential risks and ethical challenges that AI might pose. These sentiments are reflective of a growing awareness among students of the ethical responsibilities involved in the use of AI tools. This ethical awareness manifests itself in a self-directed learning curve, where students show an interest and commitment to understanding the ethical implications and responsibilities associated with the use of AI in their learning. In this sense, students are not only interested in harnessing the capabilities

of AI but also show a genuine concern for using it ethically and responsibly in their educational process.

4.2. RQ2. Can the use of generative AI foster creativity and innovation in students?

The implementation of generative artificial intelligence positively influences students’ creativity and innovation. This technology provides the students the freedom to create and experiment, which encourages the development of their imagination and innovative thinking. The hands-on approach with AI-based challenges motivates students to explore new methodologies and topics, which contributes to the expansion of their academic horizons. Direct experience works as a stimulus for their creativity, enhancing skills such as critical thinking and problem-solving (Stein, 2014).

4.3. RQ3. Do teachers currently encourage the use of AI as a resource to support lectures or assignments?

Despite the educational potential of AI, 90% of students indicated that their teachers do not encourage them to use AI technologies as support tools in their classes. This points to a significant gap between students’ interest and willingness to use AI and support or promotion by educators. The lack of incentive on the part of teachers suggests an opportunity for improvement in the integration of AI in teaching, highlighting the need to educate and train teachers in these emerging technologies to maximize their potential in the classroom.

4.4. RQ4. Can the use of generative AI help with learning in other disciplines?

The use of generative AI proves useful for learning in other disciplines. Students use AI to explore deeper into various topics, design engaging learning activities, and enhance their understanding of content. This suggests that it can be a valuable tool for enhancing and supplementing learning in a wide range of subjects and topics. In this study, it was observed that students, to create more fine-tuned prompts, researched other sources, learning from them in an interactive, no-cost, game-like manner. This practice not only enriches their knowledge in the specific discipline but also fosters research skills and synthesis of information playfully and effectively. In addition, the use of generative AI allows personalizing the study and adapting resources and activities to the individual needs and interests of each student, which contributes to deeper and more personalized learning.

5. Conclusions

The AI rapid learning methodology proposed in this study has proven to be effective in motivating and fostering participation and collaboration among students, even in uncontrolled environments where they do not know each other. The proposed activities also stimulate interest in STEM-related careers, enhancing creativity and highlighting the role of AI as a support tool, while remarking that not all

tasks can be performed solely by AI. As it has been observed the sample in gender is unbalanced and given that this type of methodologies allow to stimulate interest, it would be interesting to be able to offer this type of activities in educational centers in order that there is a gender equality in the interest of pursuing technical careers.

Most of the participants indicate that they would consider using generative AI as a support tool in their classes, covering various areas of knowledge to strengthen the understanding of the content. However, 90% of them indicate that their teachers do not encourage them to use these technologies. This situation represents an opportunity for significant improvement. It would be beneficial for teachers of different subjects to be trained in these technologies to integrate them effectively into their teaching, thus allowing them to take full advantage of the educational potential of AI in the classroom. Through this formative framework, students have a direct understanding of the positive potential of AI for the future but also understand the associated risks themselves, indicating a self-directed learning curve regarding the ethical considerations of AI use.

This methodology appears to have a significant impact on students' perceptions and interest in AI. Encouraging active participation in classes by maintaining student interest, promoting technological collaboration, and enhancing students' experience with AI tools are key areas for improving education. This study highlights the importance of integrating such methodologies to not only educate but also prepare students for responsible and ethical use of AI in their future activities.

6. Acknowledgement

This activity is part of the 4^oESO+EMPRESA Program organized by the Subdirección General de Centros de Educación Secundaria de la Comunidad de Madrid, in collaboration with the CSIC Delegation in Madrid and organized and developed by the Artificial Perception Group of the Centro de Automática y Robótica. Héctor Montes is grateful to the National Research System of Panama (SNI-SENACYT) for the support provided to its members.
