

# JACOBSON RADICALS OF ORE EXTENSIONS

JOOYOUNG SHIN

ABSTRACT. Let  $R$  be a ring,  $\sigma$  be an automorphism of  $R$ , and  $D$  be a  $\sigma$ -derivation on  $R$ . We will show that if  $R$  is an algebra over a field of characteristic 0 and  $D$  is  $q$ -skew, then  $J(R[x; \sigma, D]) = I \cap R + I_0$  where  $I = \{r \in R : rx \in J(R[x; \sigma, D])\}$  and  $I_0 = \{\sum_{i \geq 1} r_i x^i : r_i \in I\}$ . We will prove that  $J(R[x; \sigma, D]) \cap R$  is nil if  $\sigma$  is locally torsion and one of the following conditions is given: (1)  $R$  is a PI-ring, (2)  $R$  is an algebra over a field of characteristic  $p > 0$  and  $D$  is a locally nilpotent derivation such that  $\sigma D = D\sigma$ . This answers partially an open question by Greenfeld, Smoktunowicz and Ziemkowski.

## 1. INTRODUCTION

Let  $R$  be a ring and  $\sigma$  be an automorphism of  $R$ . An additive map  $D : R \rightarrow R$  that satisfies  $D(ab) = \sigma(a)D(b) + D(a)b$  for all  $a, b \in R$  is called a  $\sigma$ -derivation of  $R$ . If for every  $a \in R$ , there exists an integer  $n = n_a > 0$  such that  $\sigma^n(a) = a$ , then  $\sigma$  is called locally torsion. If for every  $a \in R$ , there is an integer  $m = m_a > 0$  such that  $D^m(a) = 0$ , then  $D$  is called locally nilpotent.

An Ore extension  $R[x; \sigma, D]$  is a ring of polynomials of form  $a_n x^n + \cdots + a_1 x + a_0$  with  $n \geq 0$  and  $a_0, \dots, a_n \in R$  with standard addition and multiplication given by  $xa = \sigma(a)x + d(a)$  for all  $a \in R$ . There are two important special cases of Ore extensions. When  $\sigma = 1$ , the Ore extension is called a differential polynomial ring or a skew polynomial ring of derivation type and denoted by  $R[x; D]$ . When  $D = 0$ , the Ore extension is called a skew polynomial ring of automorphism type and denoted by  $R[x; \sigma]$ .

Let  $J(R)$  be the Jacobson radical of  $R$ . It is well-known that every element  $r_1$  in  $J(R)$  is quasi-regular which means that there exists an element  $r_2$  in  $J(R)$  such that

$$0 = r_1 + r_2 + r_1 r_2 = r_1 + r_2 + r_2 r_1.$$

One famous open question in ring theory is the Koethe conjecture asking whether every one-sided nil ideal is contained in a two-sided nil ideal [9]. In 1972, Krempa showed that Koethe conjecture is equivalent to whether a polynomial ring over a nil ring is Jacobson radical [10]. In 1956, Amitsur proved that the Jacobson radical of a

*Key words and phrases.* Jacobson radical; Ore extension; locally torsion automorphism; polynomial identity rings; locally nilpotent derivation.

polynomial ring,  $J(R[x])$ , is equal to  $(J(R[x]) \cap R)[x]$  and  $J(R[x]) \cap R$  is a nil ideal of  $R$  [1]. In 1983, Ferrero, Kishimoto, and Motose proved that  $J(R[x; D]) = (J(R[x; D]) \cap R)[x; D]$  [5]. They showed that if  $R$  is a commutative ring, then  $J(R[x; D]) \cap R$  is nil [5]. In 1980, Bedi and Ram proved that the Jacobson radical of a skew polynomial ring of automorphism type,  $J(R[x; \sigma])$ , is equal to  $K \cap J(R) + K_0$  where  $K = \{r \in R : rx \in J(R[x; \sigma])\}$  and  $K_0 = \{\sum_{i \geq 1} r_i x^i : r \in K\}$  [2]. In particular, they showed that if  $\sigma$  is locally torsion, then  $K$  is nil and so  $J(R[x; \sigma]) = K[x; \sigma]$  [2]. However, Amitsur's theorem does not hold for general Ore extensions. Bedi and Ram showed a counter-example [2]. In section 2, we will extend their result to Ore extension and show the following theorem.

**Theorem 1.** *Let  $R$  be an algebra over a field of characteristic 0. Let  $\sigma$  and  $D$  be an automorphism and a  $q$ -skew  $\sigma$ -derivation on  $R$ . Then  $R[x; \sigma, D] = I \cap J(R) + I_0$  where  $I = \{r \in R : rx \in J(R[x; \sigma, D])\}$  and  $I_0 = \{\sum_{i \geq 1} r_i x^i : r_i \in I\}$ .*

In 2016, Madill proved that if  $R$  is a polynomial identity ring, then  $J(R[x; D]) \cap R$  is nil [11]. In 2017, Smoktunowicz proved that if  $R$  is an algebra over a field  $F$  of characteristic  $p > 0$  and  $d$  is a locally nilpotent derivation on  $R$ , then  $J(R[x; D]) \cap R$  is a nil ideal of  $R$  [15]. We may wonder whether such results can be gained on Ore extensions. In 2019, Greenfeld, Smoktunowicz and Ziemkowski posed the question below. In section 3, we will give partial answers to the question.

**Question 1.** [6, Question 6.17] *Consider  $J(R[x; \sigma, D]) \cap R$ . Is it nil if we assume that  $D$  is locally nilpotent? What if we assume that  $\sigma$  is locally torsion?*

## 2. JACOBSON RADICALS OF ORE EXTENSIONS

Throughout this section, let  $R$  be an algebra over a field  $F$ . Let  $\sigma$  and  $D$  be an automorphism and a  $\sigma$ -derivation on  $R$ . If there exists a nonzero  $q \in F$  such that  $D\sigma = q\sigma D$ , then  $D$  is said to be  $q$ -skew. We can find the following useful formula in [7] and [8].

**Proposition 1.** *Let  $\sigma$  be an endomorphism of  $R$ , and  $D$  be a  $q$ -skew  $\sigma$ -derivation on  $R$ . Then for any  $r \in R$  and non-negative integer  $k$ ,*

$$x^k r = \sum_{i=0}^k \binom{k}{i}_q \sigma^i D^{k-i}(r) x^i$$

where  $\binom{k}{j}_q$  is the evaluation at  $t = q$  of a polynomial function

$$\binom{k}{j}_t = \frac{(t^k - 1)(t^{k-1} - 1) \dots (t^{k-j+1} - 1)}{(t^j - 1)(t^{j-1} - 1) \dots (t - 1)}.$$

In particular, for any positive integer  $m$ , if  $q$  is a primitive  $m$ -th root of unity, then  $\binom{km}{jm}_q = \binom{k}{j}$ .

**Lemma 1.** *Let  $\sigma$  be an automorphism on  $R$  and  $D$  be a  $q$ -skew  $\sigma$ -derivation on  $R$ . Then  $J(R[x; \sigma, D]) \cap R$  is closed under  $\sigma$ .*

*Proof.* Define a map  $\sigma^* : R[x; \sigma, D] \rightarrow R[x; \sigma, D]$  by  $\sigma^*(\sum_{i=0}^n a_i x^i) = \sum_{i=0}^n q^{-i} \sigma(a_i) x^i$  for any  $a_i \in R$ . Since  $\sigma$  is an automorphism and  $q$  is in a field  $F$ ,  $\sigma^*$  is well-defined and bijective. Now, we claim that  $\sigma^*$  is an automorphism. Let  $f(x) = \sum_{i=0}^n a_i x^i$  and  $g(x) = \sum_{i=0}^m b_i x^i$  for  $n \leq m$  be polynomials in  $R[x; \sigma, D]$ .

$$\begin{aligned} \sigma^*(f(x) + g(x)) &= \sigma^*\left(\sum_{i=0}^n (a_i + b_i) x^i + \sum_{i=n+1}^m b_i x^i\right) \\ &= \sum_{i=0}^n q^{-i} \sigma(a_i + b_i) x^i + \sum_{i=n+1}^m q^{-i} \sigma(b_i) x^i \\ &= \sum_{i=0}^n (q^{-i} \sigma(a_i) + q^{-i} \sigma(b_i)) x^i + \sum_{i=n+1}^m q^{-i} \sigma(b_i) x^i \\ &= \sum_{i=0}^n q^{-i} \sigma(a_i) x^i + \sum_{i=0}^m q^{-i} \sigma(b_i) x^i \\ &= \sigma^*(f(x)) + \sigma^*(g(x)). \end{aligned}$$

To show that  $\sigma^*(f(x)g(x)) = \sigma^*(f(x))\sigma^*(g(x))$ , it suffices to show that  $\sigma^*(ax^n bx^m) = \sigma^*(ax^n)\sigma^*(bx^m)$ . Since  $D$  is  $q$ -skew, by Proposition 1

$$\begin{aligned} \sigma^*(ax^n bx^m) &= \sigma^*\left(\sum_{i=0}^n \binom{n}{i}_q a \sigma^i D^{n-i}(b) x^{i+m}\right) \\ &= \sum_{i=0}^n \binom{n}{i}_q q^{-(i+m)} \sigma(a \sigma^i D^{n-i}(b)) x^{i+m} \\ &= \sum_{i=0}^n \binom{n}{i}_q q^{-(i+m)} \sigma(a) \sigma^{i+1} D^{n-i}(b) x^{i+m} \\ &= \sum_{i=0}^n \binom{n}{i}_q q^{-(i+m)} q^{-(n-i)} \sigma(a) \sigma^i D^{n-i} \sigma(b) x^{i+m} \\ &= q^{-n-m} \sigma(a) \left( \sum_{i=0}^n \binom{n}{i}_q \sigma^i D^{n-i} \sigma(b) x^{i+m} \right) \\ &= (q^{-n} \sigma(a) x^n) (q^{-m} \sigma(b) x^m) \\ &= \sigma^*(ax^n) \sigma^*(bx^m). \end{aligned}$$

Thus,  $\sigma^*$  is an automorphism on  $R[x; \sigma, D]$ . We know that Jacobson radicals are closed under isomorphisms. That means that  $\sigma^*(J(R[x; \sigma, D])) \subseteq J(R[x; \sigma, D])$ . Then for any  $a \in J(R[x; \sigma, D]) \cap R$ , we have that  $\sigma(a) = \sigma^*(a) \in J(R[x; \sigma, D]) \cap R$ .

□

**Lemma 2.** *Let  $R$  be a ring,  $\sigma$  be an automorphism of  $R$ , and  $D$  be a  $q$ -skew  $\sigma$ -derivation on  $R$ . Then,  $J(R[x; \sigma, D]) \cap R$  is a  $D$ -ideal of  $R$ .*

*Proof.* Since  $J(R[x; \sigma, D])$  is an ideal of  $R[x; \sigma, D]$ ,  $J(R[x; \sigma, D]) \cap R$  is an ideal of  $R$ . Take  $a \in J(R[x; \sigma, D]) \cap R$ . By Lemma 1,  $\sigma(a) \in J(R[x; \sigma, D]) \cap R$ . Let  $R^*$  be a ring  $R$  with adjoined identity. We know that  $J(R[x; \sigma, D])$  is an ideal of  $R^*[x; \sigma, D]$ . Then,  $xa$  and  $\sigma(a)x$  are in  $J(R[x; \sigma, D])$ . We get that  $D(a) = xa - \sigma(a)x \in J(R[x; \sigma, D])$ . Since  $D(a) \in R$ , thus  $D(a) \in J(R[x; \sigma, D]) \cap R$ . □

From Lemma 1 and 2, we can define  $(J(R[x; \sigma, D]) \cap R)[x; \sigma, D]$ . It is an ideal of  $R[x; \sigma, D]$ . However, in general, the equality

$$J(R[x; \sigma, D]) = (J(R[x; \sigma, D]) \cap R)[x; \sigma, D]$$

is false. One can find the following counterexample in [2, Example 3.5].

**Example 1.** [2, Example 3.5] *Let  $R = \bigoplus_{i \in \mathbb{Z}} S_i$  where  $S_i = S$  is an arbitrary ring which is not Jacobson radical. Let  $\sigma : R \rightarrow R$  be an automorphism such that  $\sigma(\sum_{i \in \mathbb{Z}} a_i) = \sum_{i \in \mathbb{Z}} a_{i-1}$ . Consider  $R[x; \sigma]$ . Let  $K = \{r \in R : rx \in J(R[x; \sigma])\}$ . Take any  $a = \sum_{i \in \mathbb{Z}} a_i \in R$ . If  $a_i = 0$  for all  $i \notin [m, n]$ , then  $(axR[x; \sigma])^{n-m+2} = 0$ . Thus,  $K = R$ . Since  $J(R[x; \sigma]) = K \cap J(R) + K_0$  where  $K_0 = \{\sum_{i \geq 1} r_i x^i : r \in K\}$ , so  $J(R[x; \sigma]) = J(R) + K_0$ . Since  $J(R) = \bigoplus_{i \in \mathbb{Z}} J(S_i)$ , we obtain that  $J(R[x; \sigma]) \neq J(R)[x; \sigma]$ .*

Now, one may ask the following question.

**Question 2.** *When is  $J(R[x; \sigma, D])$  equal to  $J(R[x; \sigma, D]) \cap R$ ? If  $\sigma$  is locally torsion or  $D$  is locally nilpotent, then is  $J(R[x; \sigma, D])$  equal to  $J(R[x; \sigma, D]) \cap R$ ?*

We will follow the idea of Bedi and Ram and prove Theorem 1. Suppose that  $R$  does not have identity 1. Consider  $R^* = R \oplus F$  which is the Dorroh extension of  $R$  with componentwise addition and multiplication defined by  $(r_1, m_1)(r_2, m_2) = (r_1 r_2 + m_2 r_1 + m_1 r_2, m_1 m_2)$  for  $r_1, r_2 \in R$  and  $m_1, m_2 \in F$ . Then  $R^*$  has identity  $(0, 1)$  and  $R$  is a  $F$ -subalgebra of  $R^*$ . Define  $\sigma^*((r, m)) = (\sigma(r), m)$  and  $D^*((r, m)) = (D(r), 0)$  for any  $(r, m) \in R \oplus F$ . We can check that  $\sigma^*$  and  $D^*$  are an automorphism and  $\sigma^*$ -derivation on  $R \oplus F$ . Since  $R^*[x; \sigma^*, D^*]/R[x; \sigma, D] \cong F[x]$  and  $F$  is a field, so  $J(R^*[x; \sigma^*, D^*]) = J(R[x; \sigma, D])$ . Thus, we can assume that  $R$  has identity.

One can find the following definitions and some useful lemmas in [12]. Let  $S$  be a ring with identity 1 and  $R$  be a subring of  $S$  with the same 1. Let  $V_S$  be a  $S$ -module and let  $W_S$  be a submodule of  $V_S$ . If there exists a  $S$ -submodule  $U_S$  of  $V_S$  such that  $V_S = W_S + U_S$ , then we write  $W_S | V_S$ . The set  $\{y_1 = 1, y_2, \dots, y_n\}$  is called a normalizing basis for  $S$  over  $R$  if the following conditions are satisfied:

- (1) every element  $r$  of  $S$  can be written uniquely as

$$r = \beta_1 y_1 + \beta_2 y_2 + \dots + \beta_n y_n$$

for some  $\beta_1, \beta_2, \dots, \beta_n \in R$ ,

- (2) there exist automorphisms  $\phi_1, \phi_2, \dots, \phi_n$  of  $R$  such that  $y_i\beta = \phi_i(\beta)y_i$  for all  $\beta \in R$ .

**Lemma 3.** [12, Theorem 16.3] *Let  $S$  be a ring with identity 1 and let  $R$  be a subring with the same 1. If  $\{y_1 = 1, y_2, \dots, y_n\}$  is a normalizing basis for  $S$  over  $R$ , then*

$$(J(S))^n \subseteq J(R)S \subseteq J(S).$$

**Lemma 4.** [12, Theorem 16.5] *Let  $S$  be a ring and  $R$  be a subring with the same identity 1. Suppose that as left  $R$ -modules, we have  $R_R|S_R$ . Then  $J(S) \cap R \subseteq J(R)$ .*

**Lemma 5.** *Let  $R$  be an algebra over a field  $F$ . Let  $\sigma$  and  $D$  be an automorphism and  $\sigma$ -derivation on  $R$ .*

- (1) *If  $f(x) = a_nx^n + \dots + a_1x + a_0$  is a nonzero polynomial in  $J(R[x; \sigma, D])$ , then  $J(R[x; \sigma, D])$  has a monomial  $ma_nx^n$  for some  $m \in \mathbb{Z}$ .*  
 (2) *If  $f(x) = x^n a_n + \dots + xa_1 + a_0$  is a nonzero polynomial in  $J(R[x; \sigma, D])$ , then  $J(R[x; \sigma, D])$  has a monomial  $x^n(ma_n)$  for some  $m \in \mathbb{Z}$ .*

*Proof.* We will show that the first statement holds. The second statement can be shown similarly.

Assume that  $R$  has identity. Let  $f(x) = a_nx^n + \dots + a_1x + a_0$  be a nonzero polynomial in  $J(R[x; \sigma, D])$ . If  $n = 0$ , it is trivial. Suppose that  $n \geq 1$ . We will consider two cases: 1. characteristic of  $F$  is 0, 2. characteristic of  $F$  is a prime  $p \neq 0$ .

Case 1. Let  $\zeta$  be a complex primitive  $(n+1)$ -th root of unity and  $S = R \otimes_{\mathbb{Z}} \mathbb{Z}[\zeta]$ . Then,  $R$  and  $\mathbb{Z}[\zeta]$  are contained in  $S$  [4, Chapter II, §3, no.7, Corollary 1]. Define  $\sigma' : S \rightarrow S$  by  $\sigma'(r \otimes m) = \sigma(r) \otimes m$ . We can check that  $\sigma'$  is an automorphism on  $S$ . Define  $D' : S \rightarrow S$  by  $D'(r \otimes m) = D(r) \otimes m$ . We can check that  $D'$  is a  $\sigma'$ -derivation on  $R$ . Now,  $R[x; \sigma, D] \subseteq S[x; \sigma', D']$  and  $S[x; \sigma', D']$  has a normalizing basis over  $R[x; \sigma, D]$ . So,  $f(x) \in J(S[x; \sigma', D'])$  by Lemma 3.

Let  $\beta_1, \beta_2, \dots, \beta_{n+1}$  be  $n+1$  distinct units of  $\mathbb{Z}[\zeta]$ . Define maps  $\lambda_{\beta_i} : S[x; \sigma', D'] \rightarrow S[x; \sigma', D']$  by  $\lambda_{\beta_i}(\sum_{j=0}^k s_j x^j) = \sum_{j=0}^k s_j \beta_i^j x^j$  for any  $s_j \in S$ . Since  $\sigma'(\beta_i) = \beta_i$  and  $D'(\beta_i) = 0$ , they are well-defined automorphisms of  $S[x; \sigma', D']$ . Thus,  $\lambda_{\beta_i}(f(x)) \in J(S[x; \sigma', D'])$ . We obtain  $da_nx^n \in J(S[x; \sigma', D'])$  where nonzero  $d \in \mathbb{Z}[\zeta]$  is the value of the Vandermonde determinant. Let  $d = d_1, d_2, \dots, d_t$  be the conjugates of  $d$  in the Galois extension  $\mathbb{Q}[\zeta]$  of  $\mathbb{Q}$ . Then  $m := d_1 d_2 \dots d_t \in \mathbb{Q}$ . Since  $d = d_1 \in \mathbb{Z}[\zeta]$ , all  $d_i \in \mathbb{Z}[\zeta]$  for  $i = 1, 2, \dots, t$ . So,  $m \in \mathbb{Z}[\zeta] \cap \mathbb{Q} = \mathbb{Z}$ . Thus,  $ma_nx^n \in J(S[x; \sigma', D']) \cap R[x; \sigma, D]$ . But,  $R[x; \sigma, D]$  is a direct summand of  $S[x; \sigma', D']$  as  $R[x; \sigma, D]$ -module. So,  $J(S[x; \sigma', D']) \cap R[x; \sigma, D] \subseteq J(R[x; \sigma, D])$  by Lemma 4. Hence,  $ma_nx^n \in J(R[x; \sigma, D])$ .

Case 2. Consider the extension  $S = R \otimes_{\mathbb{Z}_p} K$  where  $K$  is a finite field containing  $\mathbb{Z}_p$  and  $|K| > n+1$ . Similar to Case 1, we obtain that  $da_nx^n \in J(S[x; \sigma', D'])$  for some nonzero  $d \in K$ . Thus,  $a_nx^n \in J(R[x; \sigma, D])$ .  $\square$

**Corollary 1.** *Let  $R$  be an algebra over a field  $F$ . Let  $\sigma$  and  $D$  be an automorphism and  $\sigma$ -derivation on  $R$ . Every polynomial of minimal degree in  $J(R[x; \sigma, D])$  is a monomial.*

*Proof.* Let  $f(x) = a_n x^n + \cdots + a_1 x + a_0$  be a polynomial in  $J(R[x; \sigma, D])$  with minimal degree. By Lemma 5, we know that  $ma_n x^n \in J(R[x; \sigma, D])$  for some  $m \in \mathbb{Z}$ . Then  $mf(x) - ma_n x^n \in J(R[x; \sigma, D])$ . However,

$$mf(x) - ma_n x^n = ma_{n-1} x^{n-1} + \cdots + ma_1 x + ma_0.$$

By the minimality of degree,  $mf(x) - ma_n x^n = 0$  and so  $mf(x) = ma_n x^n$ . If characteristic of  $F$  is zero, then  $f(x) = a_n x^n$ . If characteristic of  $F$  is a prime  $p \neq 0$ , then  $m = 1$  by the proof of Lemma 5 and so  $f(x) = a_n x^n$ .

Similarly, if  $f(x) = x^n a_n + \cdots + x a_1 + a_0$  has the minimal degree in  $J(R[x; \sigma, D])$ , then we can get that  $f(x) = x^n a_n \in J(R[x; \sigma, D])$ .  $\square$

Let  $R$  be an algebra over a field  $F$  of characteristic 0. Suppose that  $D$  is  $q$ -skew. Let  $k$  be any non-negative integer. Let  $A = \{r \in R : rx^k \in J(R[x; \sigma, D])\}$ . First,  $0 \in A$ . Since  $J(R[x; \sigma, D])$  is an ideal of  $R[x; \sigma, D]$ , we have that for any  $a, b \in A$ ,  $(a+b)x^k = ax^k + bx^k \in J(R[x; \sigma, D])$ . So,  $A$  is closed under addition. Since  $rax^k \in J(R[x; \sigma, D])$  for any  $a \in A$  and  $r \in R$ , we have that  $A$  is closed under left multiplication, so  $A$  is a left ideal of  $R$ . Now, we will show that  $A$  is a right ideal. Take any  $a \in A$  and  $r \in R$ . Since  $\sigma$  is an automorphism on  $R$ , there is an element  $t$  in  $R$  such that  $\sigma^k(t) = r$ . Consider  $ax^k t$ . Since  $J(R[x; \sigma, D])$  is an ideal of  $R[x; \sigma, D]$ ,  $ax^k t \in J(R[x; \sigma, D])$ .

$$ax^k t = a\sigma^k(t)x^k + \sum_{i=0}^{k-1} \binom{k}{i}_q \sigma^i D^{k-i}(t)x^i.$$

By Lemma 5, we know that  $ma\sigma^k(t)x^k \in J(R[x; \sigma, D])$  for some  $m \in \mathbb{Z}$ . Since  $F$  is of characteristic 0, we obtain that  $a\sigma^k(t)x^k \in J(R[x; \sigma, D])$ . Since  $arx^k = a\sigma^k(t)x^k$ , we obtain that  $ar \in A$ . Therefore,  $A$  is an ideal of  $R$ .

**Lemma 6.** *Let  $R$  be an algebra over a field  $F$  of characteristic 0. Let  $\sigma$  and  $D$  be an automorphism and a  $q$ -skew  $\sigma$ -derivation on  $R$ . If  $J(R[x; \sigma, D]) \neq 0$ , then  $I := \{r \in R : rx \in J(R[x; \sigma, D])\} \neq 0$ .*

*Proof.* Since  $J(R[x; \sigma, D]) \neq 0$ , let  $f(x) = a_n x^n + \cdots + a_1 x + a_0$  be a nonzero polynomial of minimal degree  $n$  in  $J(R[x; \sigma, D])$ . If  $n = 0$ , then trivially  $a_0 x \in J(R[x; \sigma, D])$ . If  $n = 1$ , then  $a_1 x \in J(R[x; \sigma, D])$  by Corollary 1. Assume that  $n \geq 2$ . By Corollary 1,  $f(x) = a_n x^n \in J(R[x; \sigma, D])$ . We claim that  $a_n x \in J(R[x; \sigma, D])$  which is a contradiction to the minimality of degree in  $J(R[x; \sigma, D])$ . Take any element  $r \in R$ .

Then  $f(x)r = a_n x^n r \in J(R[x; \sigma, D])$ . Since  $D$  is  $q$ -skew, by Proposition 1

$$f(x)r = a_n x^n r = \sum_{i=0}^n \binom{n}{i}_q a_n \sigma^i D^{n-i}(r) x^i. \quad (1)$$

Since its degree is  $n$ , Corollary 1 gives us that  $f(x)r = a_n \sigma^n(r) x^n$ . So, the term of degree  $n-1$  has the coefficient  $\binom{n}{n-1}_q a_n \sigma^{n-1} D(r) = 0$ .

Since  $\binom{n}{n-1}_q = \frac{q^n-1}{q-1} = q^{n-1} + \dots + q + 1$  is in the field  $F$ ,  $a_n \sigma^{n-1} D(r) = 0$ . Since  $D\sigma = q\sigma D$ , we obtain that  $a_n D\sigma^{n-1}(r) = q^{n-1} a_n \sigma^{n-1} D(r) = 0$ . Since we took  $r$  arbitrarily and  $\sigma$  is an automorphism, we obtain that  $a_n D(R) = 0$ . Thus, for any integer  $k$  and element  $r \in R$ ,

$$a_n x^k r = \sum_{i=0}^k \binom{k}{i}_q a_n \sigma^i D^{k-i}(r) x^i = \sum_{i=0}^k \binom{k}{i}_q q^{-i(k-i)} a_n D^{k-i} \sigma^i(r) x^i = a_n \sigma^k(r) x^k.$$

Let  $A = \{r \in R : r x^n \in J(R[x; \sigma, D])\}$ . We know that  $A$  is an ideal of  $R$  and  $a_n \in A$ . So, we can check that  $(a_n x R[x; \sigma, D])^n \subseteq A_n R[x; \sigma, D]$  where  $A_n = \{a x^n : a \in A\}$ . Indeed, for any non-negative integers  $k_1, k_2$  and elements  $b_1, b_2 \in R$ ,

$$\begin{aligned} (a_n x b_1 x^{k_1})(a_n x b_2 x^{k_2}) &= (a_n x b_1 x^{k_1}) a_n \sigma(b_2) x^{k_2+1} \\ &= a_n x b_1 \sum_{i=0}^{k_1} \binom{k_1}{i}_q \sigma^i D^{k_1-i}(a_n \sigma(b_2)) x^{k_2+1+i} \\ &= a_n \sum_{i=0}^{k_1} \binom{k_1}{i}_q \sigma(b_1 \sigma^i D^{k_1-i}(a_n \sigma(b_2))) x^{k_2+2+i} \end{aligned}$$

Since  $A_n \subseteq J(R[x; \sigma, D])$ , hence  $a_n x \in J(R[x; \sigma, D])$ . □

Let  $R$  be an algebra over a field  $F$  of characteristic 0. Let  $\sigma$  and  $D$  be an automorphism and a  $q$ -skew  $\sigma$ -derivation on a ring  $R$ . We know that  $I$  in Lemma 6 is an ideal of  $R$ . Now, we claim that  $I$  is  $(\sigma, D)$ -stable.

First, we will show that  $I$  is  $\sigma$ -stable. Define a map  $\alpha : R[x; \sigma, D] \rightarrow R[x; \sigma, D]$  by  $\alpha(\sum_{i=0}^n a_i x^i) = \sum_{i=0}^n q^{-i} \sigma(a_i) x^i$  for any  $a_i \in R$ . Since  $\sigma$  is an automorphism,  $\alpha$  is a well-defined automorphism. We know that  $\alpha(J(R[x; \sigma, D])) \subseteq J(R[x; \sigma, D])$ . Thus, for any  $r \in I$ ,  $q^{-1} \sigma(r) x = \alpha(rx) \in J(R[x; \sigma, D])$  and so  $q^{-1} \sigma(r) \in I$ . Since  $I$  is an ideal of  $R$ , thus  $\sigma(r) = q(q^{-1} \sigma(r)) \in I$  and  $I$  is  $\sigma$ -stable. Moreover, since  $\sigma$  is an automorphism and so  $D\sigma^{-1} = q^{-1} \sigma^{-1} D$ , we can see that  $I$  is  $\sigma^{-1}$ -stable. That means that  $I$  is  $\sigma$ -invariant.

Now, let's show that  $I$  is  $D$ -stable. Take any  $r \in I$ . Since  $I$  is  $\sigma$ -stable, we know that  $\sigma(r) x \in J(R[x; \sigma, D])$ . Then  $xr - D(r) = \sigma(r) x \in J(R[x; \sigma, D])$ . By Lemma 5,  $x(mr) \in J(R[x; \sigma, D])$  for some  $m \in \mathbb{Z}$ . Since  $F$  is of characteristic 0,  $xr \in J(R[x; \sigma, D])$ . Thus,  $D(r) = xr - \sigma(r) x \in J(R[x; \sigma, D])$  and  $I$  is  $D$ -stable.

*Proof of Theorem 1.* We assume that  $R$  has identity. First, we will show that  $I \cap J(R) + I_0 \subseteq J(R[x; \sigma, D])$ . Since  $J(R[x; \sigma, D])$  is an ideal of  $R[x; \sigma, D]$ , it is clear that  $I_0$  is a subset of  $J(R[x; \sigma, D])$ . Let  $r \in I \cap J(R)$ . Take any polynomial  $x^n r_n + \cdots + xr_1 + r_0 \in R[x; \sigma, D]$ . Let  $\beta = r(x^n r_n + \cdots + xr_1 + r_0)$ . Then  $\beta = f(x) + rr_0$  where  $f(x) \in rR[x; \sigma, D]$ . Since  $r \in I$ , so  $rx \in J(R[x; \sigma, D])$  and  $f(x) \in J(R[x; \sigma, D])$ . Since  $r \in J(R)$ , so  $rr_0$  has the quasi-inverse  $b$  and we obtain that

$$\beta b = f(x)b + rr_0 b = f(x)b - (rr_0 + b) = f(x)b - (\beta - f(x) + b).$$

We know that  $\beta + b + \beta b = f(x)b + f(x) \in J(R[x; \sigma, D])$ . There is  $c \in J(R[x; \sigma, D])$  such that  $\beta + b + \beta b + c + (\beta + b + \beta b)c = 0$ . So,  $\beta + (b + c + bc) + \beta(b + c + bc) = 0$  and thus  $\beta$  is quasi-regular and so  $rR[x; \sigma, D]$  is a quasi-regular right ideal. Therefore,  $r \in J(R[x; \sigma, D])$  and  $I \cap J(R) \subseteq J(R[x; \sigma, D])$ .

Now, let's show that  $J(R[x; \sigma, D]) \subseteq I \cap J(R) + I_0$ . We know that  $I$  is an ideal of  $R$ . Define a map  $\bar{\sigma} : R/I \rightarrow R/I$  by  $\bar{\sigma}(r + I) = \sigma(r) + I$  for any  $r \in R$ . Since  $I$  is  $\sigma$ -invariant and  $\sigma$  is an automorphism of  $R$ ,  $\bar{\sigma}$  is a well-defined automorphism on  $R/I$ . Define a map  $\bar{D} : R/I \rightarrow R/I$  by  $\bar{D}(r + I) = D(r) + I$  for any  $r \in R$ . Since  $I$  is  $D$ -stable,  $\bar{D}$  is well-defined. Since  $D$  is a  $\sigma$ -derivation on  $R$ ,  $\bar{D}$  is a  $\bar{\sigma}$ -derivation on  $R/I$ . Consider  $(R/I)[x; \bar{\sigma}, \bar{D}]$ . We define another map  $\theta : R[x; \sigma, D] \rightarrow (R/I)[x; \bar{\sigma}, \bar{D}]$  by  $\theta(\sum_{i=0}^n a_i x^i) = \sum_{i=0}^n (a_i + I)x^i$  for  $a_i \in R$ . We can check that  $\theta$  is a well-defined surjective homomorphism. Since the kernel of  $\theta$  is  $I[x; \sigma, D]$ , we have that  $R[x; \sigma, D]/I[x; \sigma, D] \cong (R/I)[x; \bar{\sigma}, \bar{D}]$ . We claim that  $J((R/I)[x; \bar{\sigma}, \bar{D}]) = 0$ . Let  $(r + I)x \in J((R/I)[x; \bar{\sigma}, \bar{D}])$ . We can see that

$$\frac{R[x; \sigma, D]rx + I[x; \sigma, D]}{I[x; \sigma, D]} \text{ is a quasi-regular left ideal of } \frac{R[x; \sigma, D]}{I[x; \sigma, D]}$$

and

$$\frac{R[x; \sigma, D]rx + I[x; \sigma, D]}{I[x; \sigma, D]} \text{ is isomorphic to } \frac{R[x; \sigma, D]rx + I_0}{I_0}.$$

Since  $I_0 \subseteq J(R[x; \sigma, D])$ , so  $R[x; \sigma, D]rx + I_0 \subseteq J(R[x; \sigma, D])$  and  $R[x; \sigma, D]rx \subseteq J(R[x; \sigma, D])$ . Thus,  $rx \in J(R[x; \sigma, D])$  and  $r \in I$ . Hence,  $J((R/I)[x; \bar{\sigma}, \bar{D}]) = 0$ . Since  $J(R[x; \sigma, D]/I[x; \sigma, D]) \cong J((R/I)[x; \bar{\sigma}, \bar{D}])$ , we obtain that  $J(R[x; \sigma, D]) \subseteq I[x; \sigma, D]$ . It remains to show that a constant term of every polynomial in  $J(R[x; \sigma, D])$  is in  $J(R)$ . Let  $g(x) = b_m x^m + \cdots + b_1 x + b_0$  be a polynomial in  $J(R[x; \sigma, D])$ . Since  $g(x) \in J(R[x; \sigma, D]) \subseteq I[x; \sigma, D]$ , every coefficient  $b_i$  is contained in  $I$ . Thus,  $b_1 x, b_2 x^2, \dots, b_m x^m \in J(R[x; \sigma, D])$ . So,  $b_0 = g(x) - (b_1 x + b_2 x^2 + \cdots + b_m x^m) \in J(R[x; \sigma, D])$ . Hence,  $b_0 \in J(R[x; \sigma, D]) \cap R \subseteq J(R)$ .  $\square$

### 3. ORE EXTENSIONS WITH LOCALLY TORSION AUTOMORPHISMS

Since the multiplication on Ore extensions  $R[x; \sigma, D]$  is defined by  $xa = \sigma(a)x + D(a)$  for all  $a \in R$ , we can find the following rules.

**Lemma 7.** [6, Lemma 5.1] *Let  $R$  be a ring,  $\sigma$  be an endomorphism of  $R$ , and  $D$  be a  $\sigma$ -derivation on  $R$ . Then, in  $R[x; \sigma, D]$ , the following equation holds:*

$$x^n a = \sum_{m=0}^n \left( \sum_{\substack{\deg_{\sigma}(w)=m \\ \deg_d(w)=n-m}} w(a) \right) x^m.$$

where  $w(a) = w(\sigma, D)(a)$  is a monomial in  $\sigma$  and  $d$  at  $a$ , and  $\deg_{\sigma}(w)$  and  $\deg_D(w)$  denote respectively degrees of  $\sigma$  and  $D$  in  $w$ .

In 2011, Bergen and Grzeszczuk considered the skew power series ring  $R[[x; \sigma, D]]$  as all infinite sums in form of  $a_0 + a_1x + a_2x^2 + \dots$  for all  $a_0, a_1, a_2, \dots$  [3]. The skew power series ring is closed under standard addition. However, the multiplication given by  $xa = \sigma(a)x + D(a)$  is not necessarily well-defined. In 2019, Greenfeld, Smoktunowicz, and Ziemkowski proved that if  $D$  is locally nilpotent, the natural multiplication from  $R[x; \sigma, D]$  to  $R[[x; \sigma, D]]$  is well-defined [6].

**Lemma 8.** [6, Theorem 5.3] *Let  $R$  be a ring,  $\sigma$  be an endomorphism, and  $D$  be a locally nilpotent  $\sigma$ -derivation. Then natural multiplication from  $R[x; \sigma, D]$  to  $R[[x; \sigma, D]]$  is well-defined.*

Now, we will investigate when  $J(R[x; \sigma, D]) \cap R$  is a nil ideal of  $R$ . Specifically, we will consider Ore extensions  $R[x; \sigma, D]$  where  $\sigma$  is locally torsion. Throughout this section, the center of  $R$  is denoted by  $Z(R)$  and the nilradical of  $R$  is denoted by  $N(R)$ .

**Lemma 9.** [14, Theorem 1.6.14] *Let  $R$  be a PI ring such that  $N(R) = 0$ . Then every nonzero ideal of  $R$  intersects  $Z(R)$  nontrivially.*

**Lemma 10.** *Let  $R$  be a ring. Let  $a$  be an element in  $R$  such that  $a + N(R) \in Z(R/(N(R)))$ . If  $a^t \in N(R)$  for some positive integer  $t$ , then  $a \in N(R)$ .*

*Proof.* Since  $a^t \in N(R)$ ,  $a$  is nilpotent. Since  $a + N(R) \in Z(R/(N(R)))$ , we have that  $(a\mathbb{Z} + aR + N(R))/(N(R))$  is a nil ideal of  $R/N$  and so  $a\mathbb{Z} + aR + N(R)$  is a nil ideal of  $R$ . Thus,  $a\mathbb{Z} + aR + N(R)$  is contained in  $N(R)$ . That means that  $a \in N(R)$ .  $\square$

**Theorem 2.** *Let  $R$  be a PI ring. Let  $\sigma$  be a locally torsion automorphism of  $R$  and  $D$  be a  $\sigma$ -derivation on  $R$ . Then  $J(R[x; \sigma, D]) \cap R$  is a nil ideal of  $R$ .*

*Proof.* The approach follows [11]. Let  $S = J(R[x; \sigma, D]) \cap R$  and let  $N = N(R)$ . We know that  $S$  is an ideal of  $R$ . We will prove that  $S$  is nil. Consider a quotient ring  $L := (S + N)/N$ . Note that  $L$  is an ideal of  $R/N$ , which is a PI ring with the zero upper nilradical.

If  $L = 0$ , then  $S \subseteq N$  and so  $S$  is nil. Suppose that  $L \neq 0$ . By Lemma 9,  $L \cap Z(R/N) \neq \{0\}$ . Take a nonzero element  $a + N \in L \cap Z(R/N)$ . Then  $a \in S$ ,  $a + N \neq N$ , and  $a + N \in Z(R/N)$ . Since  $\sigma$  is locally torsion, there is an integer

$n > 0$  such that  $\sigma^n(a) = a$ . Let  $R^*$  be a ring  $R$  with adjoined identity. Since  $a \in S \subseteq J(R[x; \sigma, D])$  and  $J(R[x; \sigma, D])$  is an ideal of  $R^*[x; \sigma, D]$ , we have that  $ax^n \in J(R[x; \sigma, D])$  and so there exists  $f(x) = \sum_{i=0}^m b_i x^i \in J(R[x; \sigma, D])$  such that

$$f(x) + ax^n + f(x)ax^n = 0. \quad (2)$$

By comparing coefficients of each term, we can get that  $b_0 = b_1 = \dots = b_{n-1} = 0$ . So, write  $f(x) = \sum_{i=n}^m b_i x^i$ . By Lemma 7, equation (2) becomes

$$\begin{aligned} 0 &= \sum_{i=n}^m b_i x^i + ax^n + \left( \sum_{i=n}^m b_i x^i ax^n \right) \\ &= \sum_{i=n}^m b_i x^i + ax^n + \left( \sum_{i=n}^m \sum_{j=0}^i \sum_{\substack{\deg_\sigma(w)=j \\ \deg_d(w)=i-j}} b_i w(a) x^{n+j} \right). \end{aligned}$$

Compare coefficients of each term. From  $x^{n+m}$  term, we get

$$b_m \sigma^m(a) = 0. \quad (3)$$

From  $x^{m+i}$  for  $i = 1, 2, \dots, n-1$ , we get

$$\sum_{l=m-n+i}^m b_l w_{m-n+i, l-m+n-i}(a) = 0 \quad (4)$$

where  $w_{i, l-i}(a) = \sum_{\substack{\deg_\sigma(w)=i \\ \deg_d(w)=l-i}} w(a)$ . From  $x^{n+i}$  term for  $i = 1, 2, 3, \dots, m-n$ , we get

$$b_{n+i} + \sum_{l=i}^m b_l w_{i, l-i}(a) = 0. \quad (5)$$

From  $x^n$  term, we get

$$b_n + a + \sum_{i=n}^m b_i D^i(a) = 0. \quad (6)$$

Let  $A$  be a set of finite products of  $a, \sigma(a), \sigma^2(a), \dots, \sigma^{n-1}(a)$ . We claim that there exists some  $r_j \in A$  such that  $b_{m-j} r_j \in N$  for all  $j = 0, 1, \dots, m-n$ . We will proceed by induction on  $j$ . For  $j = 0$ , equation (3) shows  $b_m \sigma^m(a) = 0$ . Since  $\sigma^n(a) = a$ , so  $\sigma^m(a) \in A$ .

Suppose that the result holds for any  $j \leq k$  with  $k \in \{0, 1, 2, 3, \dots, m - n\}$ . First, consider the case  $k + 1 < n$ . In equation (4), replace  $i$  with  $n - k - 1$ .

$$\begin{aligned}
 0 &= \sum_{l=m-k-1}^m b_l w_{m-k-1, l-m+k+1}(a) \\
 &= b_{m-k-1} w_{m-k-1, 0}(a) + \sum_{l=m-k}^m b_l w_{m-k-1, l-m+k+1}(a) \\
 &= b_{m-k-1} \sigma^{m-k-1}(a) + \sum_{l=m-k}^m b_l w_{m-k-1, l-m+k+1}(a).
 \end{aligned} \tag{7}$$

By the inductive hypothesis, there are  $r_{m-l} \in A$  such that  $b_l r_{m-l} \in N$  for  $l = m - k, m - k + 1, \dots, m$ . Multiply each side of equation (7) by  $r_k r_{k-1} \dots r_0$ . Since  $a + N \in Z(R/N)$  and  $\sigma$  is an automorphism,  $\sigma(a) + N \in Z(R/N)$  and so  $r + N \in Z(R/N)$  for all  $r \in A$ .

$$\begin{aligned}
 0 &= b_{m-k-1} \sigma^{m-k-1}(a) r_k r_{k-1} \dots r_0 \\
 &\quad + \sum_{l=m-k}^m b_l w_{m-k-1, l-m+k+1}(a) r_k r_{k-1} \dots r_0 \\
 &= b_{m-k-1} \sigma^{m-k-1}(a) r_k r_{k-1} \dots r_0 \pmod{N}.
 \end{aligned}$$

Since  $r_{k+1} := \sigma^{m-k-1}(a) r_k r_{k-1} \dots r_0 \in A$ , the result holds.

Next, consider the case  $k + 1 \geq n$ . In equation (5), replace  $i$  with  $m - k - 1$ .

$$\begin{aligned}
 b_{n+m-k-1} + \sum_{l=m-k-1}^m b_l w_{m-k-1, l-m+k+1}(a) &= 0 \\
 b_{n+m-k-1} + b_{m-k-1} w_{m-k-1, 0}(a) + \sum_{l=m-k}^m b_l w_{m-k-1, l-m+k+1}(a) &= 0.
 \end{aligned}$$

By the inductive hypothesis, there are  $r_j$  and  $r_{k-n+1}$  in  $A$  such that  $b_{m-j} r_j \in N$  and  $b_{n+m-k-1} r_{k-n+1} \in N$  for  $0 \leq j \leq k$ . Multiply each side by  $\xi = r_0 r_1 \dots r_{k-1} r_{k-n+1} \in A$ .

$$b_{n+m-k-1} \xi + b_{m-k-1} w_{m-k-1, 0}(a) \xi + \sum_{l=m-k}^m b_l w_{m-k-1, l-m+k+1}(a) \xi = 0.$$

Since  $r + N \in Z(R/N)$  for all  $r \in A$ , thus  $b_{n+m-k-1} \xi \in N$  and  $b_l w_{m-k-1, l-m+k+1}(a) \xi \in N$  for  $m - k \leq l \leq m$ . We have that  $b_{m-k-1} w_{m-k-1, 0}(a) \xi = b_{m-k-1} \sigma^{m-k-1}(a) \xi \in N$ . We can take  $r_{k+1} := \sigma^{m-k-1}(a) \xi \in A$ .

By the claim, there exist  $r_n, r_{n+1}, \dots, r_m \in A$  such that  $b_i r_i \in N$  for  $i = n, n+1, \dots, m$ . Multiply equation (6) by  $r_n r_{n+1} \dots r_m$ . Since  $r+N \in Z(R/N)$  for all  $r \in A$ ,

$$\begin{aligned} 0 &= b_n r_n r_{n+1} \dots r_m + a r_n r_{n+1} \dots r_m + \sum_{i=n}^m b_i D^i(a) r_n r_{n+1} \dots r_m \\ &= b_n r_n r_{n+1} \dots r_m + a r_n r_{n+1} \dots r_m + \sum_{i=n}^m b_i r_n r_{n+1} \dots r_m D^i(a) \pmod{N} \\ &= a r_n r_{n+1} \dots r_m \pmod{N}. \end{aligned}$$

Since  $r_n r_{n+1} \dots r_m \in A$ , we have that  $r_n r_{n+1} \dots r_m + N = a^{t_0} (\sigma(a))^{t_1} \dots (\sigma^{n-1}(a))^{t_{n-1}} + N$  for some non-negative integers  $t_0, t_1, \dots, t_{n-1}$ . Since  $a r_n r_{n+1} \dots r_m \in N$ , we gain that  $(a \sigma(a) \sigma^2(a) \dots \sigma^{n-1}(a))^t \in N$  for some  $t \geq \max\{t_0, t_1, \dots, t_{n-1}\}$ . By Lemma 10, we know that  $a \sigma(a) \sigma^2(a) \dots \sigma^{n-1}(a) \in N$ . Let  $c_0 = a, c_1 = \sigma(a), \dots, c_{n-1} = \sigma^{n-1}(a)$ . Then  $c_0 c_1 \dots c_{n-1} \in N$ . We can find the largest integer  $k$  such that there exists  $i_1 < i_2 < \dots < i_k$  with  $c_{i_1} c_{i_2} \dots c_{i_k} \notin N$  and  $c_{i_1} c_{i_2} \dots c_{i_k} c_{i_{k+1}} \in N$  where  $c_{i_1}, \dots, c_{i_k}, c_{i_{k+1}}$  are distinct. Let  $a_1 = c_{i_1} c_{i_2} \dots c_{i_k}$ . Then  $a_1 \notin N$ ,  $a_1 \in S$ ,  $a_1 + N \in Z(R/N)$ , and  $\sigma^n(a_1) = a_1$ . Let  $a_2 = a_1 + \sigma(a_1) + \dots + \sigma^{n-1}(a_1)$ . Then  $a_2 \in S$  and  $a_2 + N \in Z(R/N)$ . If  $a_2 \in N$ , then  $a_1 a_2 \in N$  and  $a_1 \sigma^j(a_1) \in N$  for any positive integer  $j$  by the maximality of  $k$ , and so  $a_1^2 \in N$ . By Lemma 10,  $a_1 \in N$  which is a contradiction. Thus,  $a_2 \notin N$ . Moreover, since  $\sigma^n(a_1) = a_1$ , we have that  $\sigma(a_2) = a_2$ . Since  $a_2 \notin N$ ,  $a_2 \in S$ , and  $a_2 + N \in Z(R/N)$ , we can proceed a similar way to the previous steps comparing coefficients of  $g(x) + a_2 x + g(x) a_2 x = 0$  where  $g(x)$  is the quasi-inverse of  $a_2 x$ . We gain that  $a_2^p \in N$  for some positive integer  $p$ . By Lemma 10,  $a_2 \in N$  which is a contradiction. Hence,  $L = 0$ .  $\square$

**Theorem 3.** *Let  $R$  be an algebra over a field of characteristic  $p > 0$ ,  $\sigma$  be a locally torsion automorphism of  $R$ , and  $D$  be a locally nilpotent  $\sigma$ -derivation on  $R$ . If  $\sigma D = D\sigma$ , then  $J(R[x; \sigma, D]) \cap R$  is a nil ideal of  $R$ .*

*Proof.* The approach follows [15]. We know that  $J(R[x; \sigma, D]) \cap R$  is an ideal of  $R$ . We will show that  $J(R[x; \sigma, D]) \cap R$  is nil. Take any element  $a \in J(R[x; \sigma, D]) \cap R$ . Since  $\sigma$  is locally torsion and  $D$  is locally nilpotent, we can take an integer  $m > 0$  such that  $\sigma^m(a) = a$  and  $D^{p^m}(a) = 0$ . By Proposition 1, we have  $x^{mp^m} a = a x^{mp^m}$ . Let  $R^*$  be a ring  $R$  with adjoined identity. Since  $a \in J(R[x; \sigma, D]) \cap R \subseteq J(R[x; \sigma, D])$  and  $J(R[x; \sigma, D])$  is an ideal of  $R^*[x; \sigma, D]$ ,  $a x^{mp^m}$  has the quasi-inverse  $p(x) = \sum_{i=0}^t b_i x^i \in R[x; \sigma, D]$ . Let  $A$  be a subring of  $R$  generated by  $a, b_i, \sigma^l(D^j(a)), \sigma^l(D^j(b_i))$  for integers  $0 \leq i \leq t$  and  $j \geq 0$  and  $l \in \mathbb{Z}$ . Since  $\sigma D = D\sigma$ ,  $\sigma$  is an automorphism of  $A$  and  $D$  is a  $\sigma$ -derivation on  $A$ , so  $A[x; \sigma, D]$  is a subring of  $R[x; \sigma, D]$ . Note that  $a x^{mp^m}$  is quasi-regular in  $A[x; \sigma, D]$ .

Since  $D$  is locally nilpotent and  $\sigma$  is locally torsion, there is an integer  $k = mq$  for some  $q > 0$  such that  $\sigma^k(b_i) = b_i$  and  $D^{p^k}(b_i) = 0$  for all  $i = 0, 1, 2, \dots, t$ . By

Proposition 1,  $x^{kp^k} b_i = b_i x^{kp^k}$  for all  $i = 0, 1, 2, \dots, t$ . Since  $\sigma D = D\sigma$ , we have that

$$\begin{aligned} x^{kp^k} \sigma^l(D^j(b_i)) - \sigma^l(D^j(b_i)) x^{kp^k} &= x^{kp^k} \sigma^l(D^j(b_i)) - D^j(\sigma^l(b_i)) x^{kp^k} \\ &= x^{kp^k} \sigma^l(D^j(b_i)) - D^j(\sigma^{l+kp^k}(b_i)) x^{kp^k} \\ &= x^{kp^k} \sigma^l(D^j(b_i)) - \sigma^{kp^k}(\sigma^l(D^j(b_i))) x^{kp^k} \\ &= D^{kp^k}(\sigma^l(D^j(b_i))) \\ &= \sigma^l(D^{j+kp^k}(b_i)) \\ &= 0. \end{aligned}$$

Moreover, since  $k = mq$ , we can check that  $\sigma^k(a) = a$ ,  $D^{p^k}(a) = 0$ , and  $x^{kp^k} a = ax^{kp^k}$ . Similar to  $x^{kp^k} \sigma^l(D^j(b_i)) = \sigma^l(D^j(b_i)) x^{kp^k}$ , we can find that  $x^{kp^k} \sigma^l(D^j(a)) = \sigma^l(D^j(a)) x^{kp^k}$ . So,  $x^{kp^k}$  commutes with all elements in  $A$ . Therefore,  $D$  is nilpotent on  $A$ .

Consider  $A[x; \sigma, D] \subseteq A[[x; \sigma, D]]$  which is a power series ring in the indeterminate  $x$ . Recall that  $x^{mp^m} a = ax^{mp^m}$ , thus  $(ax^{mp^m})^i = a^i x^{imp^m}$ . In  $A[[x; \sigma, D]]$ , we can see that  $q(x) = (-ax^{mp^m}) + (-ax^{mp^m})^2 + (-ax^{mp^m})^3 + \dots$  is the quasi-inverse of  $ax^{p^m}$ , that is,

$$ax^{mp^m} + ((-ax^{mp^m}) + (-ax^{mp^m})^2 + \dots) + ax^{mp^m} ((-ax^{mp^m}) + (-ax^{mp^m})^2 + \dots) = 0.$$

By the uniqueness of a quasi-inverse,  $q(x) = p(x) \in A[x; \sigma, D] \subseteq A[[x; \sigma, D]]$  and so

$$\sum_{i=0}^{\infty} (-ax^{mp^m})^i = \sum_{i=0}^{\infty} (-a)^i x^{imp^m} \in A[x; \sigma, D]$$

Hence,  $a^i = 0$  for some  $i$ . □
