We present a quantum algorithm for simulating a family of Markovian master equations that can be realized through a probabilistic application of unitary channels and state preparation. Our approach employs a second-order product formula for the Lindblad master equation, achieved by decomposing the dynamics into dissipative and Hamiltonian components and replacing the dissipative segments with randomly compiled, easily implementable elements. The sampling approach eliminates the need for ancillary qubits to simulate the dissipation process and reduces the gate complexity in terms of the number of jump operators. We provide a rigorous performance analysis of the algorithm. We also extend the algorithm to time-dependent Lindblad equations, generalize the noise model when there is access to limited ancillary systems, and explore applications beyond the Markovian noise model. A new error bound, in terms of the diamond norm, for second-order product formulas for time-dependent Liouvillians is provided that might be of independent interest.

One of the first suggested applications of quantum computing was to simulate quantum mechanical systems [1]. Since Feynman's initial proposal, the field of quantum simulation has grown rapidly, resulting in numerous algorithms that offer asymptotic speed-ups over the best possible classical algorithms. Initially, much focus has been on simulating closed quantum systems [2-9], only recently has there been a significant interest in developing quantum algorithms for simulating open quantum systems [10–23]. Notable examples are algorithms to simulate a single quantum channel applied to an input quantum state [11, 15, 19], algorithms that simulate continuous-time dynamics describable by master equations [10–14, 16, 20]. Special attention is paid to dynamics generated by time-independent Lindblad master equations, since they cover the common scenario of a quantum system weakly coupled to a Markovian environment. Some examples include [10-14, 16, 20-22] with [13]achieving the current state-of-the-art asymptotic scaling. Similar to Hamiltonian simulation, the current classical Lindblad simulation algorithms are inefficient, thus efficient quantum algorithms for Lindblad simulation could prove useful for future scientific needs.

Interestingly, many of the current Lindblad simulation algorithms share common features. They deterministically implement the full set of jump operators for the Lindbladian and treat both the dissipative and unitary dynamics on equal footing. In addition, the resources required by these algorithms explicitly increase (polynomially) with respect to the number of Lindblad jump operators along with the overall norm of the Lindbladian. A missing feature in the existing algorithms is taking advantage of the fact that in many realistic open system dynamics, there are classical uncertainty regarding the effect of the environment on the system. This noise-agnostic approach can lead to situations where the noisy open system simulation algorithms can scale worse, sometimes even exponentially worse, than simulating the noiseless system! For example, naive algorithms to simulate Hamiltonian evolution in the presence of *global* depolarizing noise would require exponential time for many of the general-purpose open quantum system algorithms, given the fact that global depolarization requires exponentially many jump operators. However, such an explicit scaling with the number of jump operators can be reduced if the classical randomness, present in the description of the open system dynamics, is directly incorporated into the design of the algorithm to simulate dissipation. This strategy has recently been considered for a restricted class of Lindbladians, in which a firstorder approximation to a dissipator is used for thermal state preparation on a quantum computer [24]. It is also used to simulate continuous-time dynamics by leveraging the intrinsic noise of quantum processors [21, 22], and to design an algorithm that uses a classical processor alongside the quantum computer to reconstruct the dynamics based on a series of sampled states [25].

In this Letter, we present a quantum algorithm for simulating both the coherent and dissipative evolution of a Lindbladian, with no need for any ancilla qubits and reduced gate complexity in the number of jump operators. although for a restricted class of Lindbladians. The class of Lindbladians we consider are sums of a Hamiltonian part and a dissipator, where the dissipator is constrained to generate channels that are convex combinations of unitary channels and fixed state preparation. Although our noise model is restrictive, it does encapsulate many physically relevant dissipative processes such as both local and global depolarizing noise, dephasing and bit-flip noise, and other random Pauli channels. The algorithm we introduce uses a second-order product formula to divide the generator into its Hamiltonian part and dissipator. We then simulate the dissipative portion using a simple sampling protocol, with the Hamiltonian dynamics

being simulated using any Hamiltonian simulation algorithm preferred. The only ancillary qubits needed by the algorithm are what is needed to implement the desired Hamiltonian simulation subroutine. The scaling of the circuit with respect to simulation time and precision is  $O(T^{1.5}/\sqrt{\epsilon})$ , where T is the total simulation time and  $\epsilon$  is the accuracy in the diamond norm. This is an improvement over the  $O(T^2/\epsilon)$  scaling of [24].

We also discuss a generalization of the algorithm to simulate a family of time-dependent Lindbladians. To analyze the performance in the time-dependent case, we prove a new second-order product formula for timedependent Louvillians, consisting of an arbitrary timedependent and an arbitrary time-independent term, which might be of independent interest. Additionally, we explore how limited ancillary qubits can broaden the scope of master equations that our algorithm can simulate, for example simulating local amplitude damping noise using a few ancilla qubits. We also discuss methods to extend the algorithm to non-Markovian master equations.

Stochastically Simulatable Channels.—Let  $\mathcal{E}$  be a CPTP map that can be simulated stochastically, i.e., it can be implemented by sampling a set of quantum operations  $\{\mathcal{A}_i\}$  according to probabilities  $p_i$  such that  $\mathcal{E}(\rho) = \mathbb{E} \left[\mathcal{A}_i(\rho)\right]$  holds. Then the measurement statistics of any quantum circuit composed of multiple applications of  $\mathcal{E}$  can be reproduced by replacing any application of  $\mathcal{E}$  with an implementation of  $\mathcal{A}_i$  sampled independently. In this work we are interested in estimating the expected value of a general observable using our simulation algorithm. With the goal of designing a low-cost quantum algorithm, we restrict the operations. More specifically, we consider stochastically simulatable channels defined below.

**Definition 1.** We call  $\mathcal{E}$  a stochastically simulatable channel if it can be written as:

$$\mathcal{E}(\rho) = q\left(\sum_{i} \lambda_{i} U_{i} \rho U_{i}^{\dagger}\right) + (1-q)\rho_{f}$$
(1)

where  $U_i$  are unitary operators and  $\rho_f$  is a fixed quantum state. Scalars q and  $\lambda_i$  are constrained such that  $0 \le q \le 1$ ,  $0 \le \lambda_i \le 1$ , and  $\sum_i \lambda_i = 1$ .

The cost of implementation of  $\mathcal{E}$  solely depends on the complexity of implementation of  $\{U_i\}$  and also the preparation of  $\rho_f$ . Ideally these operations should be efficiently implementable. Some examples include when  $\{U_i\}$  are *n*-fold tensor products of single-qubit unitaries and also when they are generated by Clifford circuits.

In this work we mainly focus on simulating open quantum systems described by a Lindblad master equation, given as  $\frac{d\rho}{dt} = \mathcal{L}(\rho)$  with  $\mathcal{L} = \mathcal{H} + \mathcal{D}$ , where  $\mathcal{H}(\rho) =$   $-i[H,\rho]$  generates Hamiltonian evolution and the dissipator  $\mathcal{D}(\rho) = \sum_{\mu=1}^{m} (L_{\mu}\rho L_{\mu}^{\dagger} - \frac{1}{2}\{L_{\mu}^{\dagger}L_{\mu},\rho\})$  models the system-environment interactions. Here H is the system Hamiltonian and  $L_{\mu}$  are the Lindblad's jump operators.

An example of a class of Lindblad superoperators that satisfy Definition 1 for a small interval of time are dissipators  $\mathcal{D}$  with jump operators  $L_{\mu} = \alpha_{\mu}U_{\mu}$  for unitaries  $U_{\mu}$ . It is straightforward to check that in this case when  $\delta t \|\mathcal{D}\|_{\diamond} \leq 1$ , the operator  $e^{\delta t \mathcal{D}}$  can be approximated by a random unitary channel with arbitrarily small error [see Supplementary Material (SM)]. When  $U_{\mu}$  belongs to a group of efficiently implementable unitaries, such as *n*fold tensor products of single-qubit unitaries or Clifford circuits, then the random unitary channel fits our ideal scenario discussed above, since the complexity of implementation does not change when the unitaries are composed. This class of Lindblad master equations captures many useful families including random Pauli channels.

New Algorithm.—We now introduce a quantum algorithm to simulate Lindbladian dynamics. In its simplest form, given a time-independent Lindblad superoperator  $\mathcal{L} = \mathcal{H} + \mathcal{D}$  where  $\mathcal{H}$  is the generator of the unitary evolution and  $\mathcal{D}$  is the generator of a (approximately) stochastically simulatable map, our proposed algorithm simulates the evolution of an arbitrary input state  $\rho$  under  $\mathcal{L}$  up to time T and precision  $\epsilon$  by repeatedly implementing Lindbladian simulation gadgets depicted in FIG 1.

$$\rho \xrightarrow{n} \left[ \begin{array}{c} \mathcal{K}_{\delta t} \\ \mathcal{K}_{\delta t} \\ \end{array} \right] \xrightarrow{} \left[ \begin{array}{c} \mathcal{K}_{\delta t} \\ \mathcal{K}_{\delta t} \\ \end{array} \right]} \xrightarrow{} \left[ \begin{array}{c} \mathcal{K}_{\delta t} \\ \mathcal{K}_{\delta t} \\ \end{array} \right]}$$
repeat *r*-times

FIG. 1: Simulation gadget

Each Lindbladian simulation gadget is built of two different subroutines, one implementing the map  $\mathcal{K}_{\delta t}$  which approximates  $e^{\frac{\delta t}{2}\mathcal{H}}$  and can be executed using any choice of Hamiltonian simulation algorithm, and the other,  $\mathcal{N}_{\delta t}$ which approximates  $e^{\delta t\mathcal{D}}$  in expectation using a simple sampling routine.

As discussed before, we assume  $e^{\delta t \mathcal{D}}$  is approximately stochastically simulatable, i.e.,  $e^{\delta t \mathcal{D}} = \mathcal{N}_{\delta t} + \mathcal{O}(\delta t^3)$ , where  $\mathcal{N}_{\delta t}$  satisfies Definition 1. Since  $\mathcal{N}_{\delta t}$  is stochastically simulatable we can write

$$\mathcal{N}_{\delta t}(\rho) = \sum_{i} p_i(\delta t) \mathcal{A}_{\delta t}^{(i)}(\rho) = \mathbb{E}_{i \sim p_i(\delta t)} \left[ \mathcal{A}_{\delta t}^{(i)}(\rho) \right], \quad (2)$$

where:

$$\mathcal{A}_{\delta t}^{(i)}(\rho) = \begin{cases} P_{\delta t}(\rho) = \rho_{\delta t} \text{ for } i = 0, \\ U_{\delta t}^{(i)} \rho U_{\delta t}^{(i)\dagger} \text{ otherwise }, \end{cases}$$
(3)

along with probabilities

$$p_i(\delta t) = \begin{cases} 1 - q(\delta t) \text{ for } i = 0, \\ q(\delta t)\lambda_i(\delta t) \text{ otherwise.} \end{cases}$$
(4)

Therefore our subroutine  $\mathcal{N}_{\delta t}$  can approximate  $e^{\delta t \mathcal{D}}$  up to  $\mathcal{O}(\delta t^3)$ , by simply sampling  $i \sim p_i(\delta t)$  and applying the operation  $\mathcal{A}_{\delta t}^{(i)}$ . Thus the gate complexity of  $\mathcal{N}_{\delta t}$  is independent of the number of jump operators and only depends on the complexity of implementing unitaries  $U_{\delta t}^{(i)}$ and fixed state preparation oracle  $P_{\delta t}$  which replaces the state of the system with a fixed state. This procedure assures the measurement statistics over many different compilations of the quantum circuit implementing  $\mathcal{N}_{\delta t}$ will replicate the measurement statistics of a single circuit implementing  $\mathcal{N}_{\delta t}$  exactly. Thus when compiling each of the Lindbladian simulation gadgets, we independently sample  $i \sim p_i(\delta t)$  and implement the operation  $\mathcal{A}_{\delta t}^{(i)}$  in place of  $\mathcal{N}_{\delta t}$  in the gadget. The full algorithm consists of sequentially repeating the blocks of  $\mathcal{K}_{\delta t}$  using any closed-system quantum simulation algorithm of choice, and sampling  $\mathcal{A}_{\delta t}^{(i)}$  for each  $\mathcal{N}_{\delta t}$  block. The number of repetitions r, required to guarantee a desired accuracy  $\epsilon$ , would determine the gate complexity of the algorithm.

Algorithm Analysis.—At a high level, to analyze the performance of the algorithm, we leverage a product formula for Lindblad superoperators to split up the dynamics into its Hamiltonian part and a stochastically simulatable dissipator. The total simulation time and precision then constrain the individual subroutines' precision and simulation time. Since we can implement  $\mathcal{N}_{\delta t}$  without error, our constraints only apply to the Hamiltonian simulation subroutine  $\mathcal{K}_{\delta t}$ .

First, we introduce some notation. The diamond norm of a linear map  $\mathcal{L}$  over linear operators on a finite-dimensional Hilbert space is defined as  $\|\mathcal{L}\|_{\diamond} = \max_{\|\rho\|_{1}=1} \|\mathcal{I} \otimes \mathcal{L}(\rho)\|_{1}$ , where  $\|\cdot\|_{1}$  denotes the trace norm and  $\mathcal{I}$  the identity map. Following [20] we define  $\|\mathcal{L}\|_{pauli}$  of a Lindblad superoperator  $\mathcal{L}$  as  $\|\mathcal{L}\|_{pauli} = \sum_{k=0}^{s-1} \beta_{0k} + \sum_{\mu=1}^{m} \left(\sum_{k=0}^{s-1} \beta_{\mu k}\right)^{2}$ , where  $H = \sum_{k=0}^{s-1} \beta_{0k} V_{0k}$ , and  $L_{\mu} = \sum_{k=0}^{s-1} \beta_{\mu k} V_{\mu k}$  with  $\beta_{\mu k} > 0$  and  $V_{\mu k}$  an n-fold tensor product of Pauli operators with arbitrary phases. Finally, we denote the total simulation time and precision by T and  $\epsilon$  respectively.

We proceed by finding an upper-bound on the error between r applications of our subroutines and the true evolution generated by  $\mathcal{L}$ . Assuming  $\left(\frac{\|\mathcal{H}\|_{\diamond}}{2} + \|\mathcal{D}\|_{\diamond}\right) \delta t \leq 1$ , we can apply a second-order product formula [26] (see Theorem 2 for our generalized version), alongside the sub-multiplicative and additive properties of the diamond norm [27] to get:

$$\frac{\left\|e^{T\mathcal{L}} - (\mathcal{K}_{\delta t} \circ \mathcal{N}_{\delta t} \circ \mathcal{K}_{\delta t})^{r}\right\|_{\diamond}}{3} \leq \frac{\left\|[\mathcal{H}, \mathcal{D}]\right\|_{\diamond}}{2} \left(\frac{\left\|\mathcal{H}\right\|_{\diamond}}{2} + \left\|\mathcal{D}\right\|_{\diamond}\right) r \delta t^{3} + 2r \left(\epsilon_{H} + \epsilon_{D}\right), \quad (5)$$

where  $\epsilon_H = \|e^{\delta t \mathcal{H}} - \mathcal{K}_{\delta t}\|_{\diamond}$  and  $\epsilon_D = \|e^{\delta t \mathcal{D}} - \mathcal{N}_{\delta t}\|_{\diamond}$ , which represent the errors each of our subroutines incur.

$$\epsilon_D = \left\| e^{\delta t \mathcal{D}} - \mathcal{N}_{\delta t} \right\|_{\diamond} \le c_0 (\|\mathcal{D}\|_{\diamond} \, \delta t)^3, \tag{6}$$

where  $c_0$  is a constant determined by the specifics of the dissipator  $\mathcal{D}$ . As discussed before, dissipators with jump operators of the form  $L_{\mu} = \alpha_{\mu}U_{\mu}$  can be approximated by a stochastically simulatable channel up to arbitrary small error. Such dissipators are an example of when requirement (6) is satisfied. Using  $\|\mathcal{L}\|_{\diamond} \leq 2 \|\mathcal{L}\|_{pauli}$  from [20] to carry out the upper bounds in terms of  $\|\cdot\|_{pauli}$  gives us a way to easily compare to the state-of-the-art Lindblad simulation algorithms [14, 20, 25]. Thus our bound becomes,

$$\begin{aligned} \left\| e^{T\mathcal{L}} - \left( \mathcal{K}_{\delta t} \circ \mathcal{N}_{\delta t} \circ \mathcal{K}_{\delta t} \right)^{r} \right\|_{\diamond} &\leq \\ \frac{8}{3} r (1 + 6c_{0}) \left( \left\| \mathcal{L} \right\|_{pauli} \delta t \right)^{3} + 2r\epsilon_{H}. \end{aligned}$$
(7)

To keep the precision of the total simulation over time T with-in total error of  $O(\epsilon)$  equation (7) implies we must take  $r = O\left(\sqrt{\frac{1+6c_0}{\epsilon}}(\|\mathcal{L}\|_{pauli}T)^{1.5}\right)$ , and  $\epsilon_H = O(\epsilon/r)$ . All that is left is to design an implementation of the Hamiltonian simulation subroutine.

Choosing to use the truncated Taylor series algorithm of [7] provides the gate complexity for the subroutine to be  $\tilde{O}\left(\delta t \|\mathcal{H}\|_{pauli} sn \log\left(\frac{\delta t \|\mathcal{H}\|_{pauli}}{\epsilon_H}\right)\right)$ , where *n* is the number of qubits and *s* in the number of Pauli terms in the Hamiltonian. The total gate complexity is just the subroutine's cost multiplied by *r*. Since subroutine  $\mathcal{N}_{\delta t}$  does not require any ancilla to implement, the only ancilla cost of the algorithm comes from our implementation of  $\mathcal{K}_{\delta t}$ . Assuming we can reset the ancilla registers before each  $\mathcal{K}_{\delta t}$  subroutine, algorithm of Ref. [7] gives us the ancilla cost for implementing  $\mathcal{K}_{\delta t}$  to be  $\tilde{O}\left(\log(s)\log(\delta t/\epsilon_H)\right)$ .

Alternatively, we could use an algorithm based on product formulas [28, 29] to implement the Hamiltonian simulation subroutine  $\mathcal{K}_{\delta t}$ , which would remove the need for any ancilla, at the expense of a worse gate complexity to simulate the Hamiltonian dynamics. We can summarize the analysis in the following theorem.

**Theorem 1.** Let  $\mathcal{L} = \mathcal{H} + \mathcal{D}$  be a Lindbladian with Hamiltonian portion  $\mathcal{H}$  and dissipative portion  $\mathcal{D}$ . Assume  $\mathcal{D}$  generates an approximately stochastically simulatable channel satisfying (6). Then there exists a quantum algorithm that simulates  $e^{T\mathcal{L}}$  up to precision  $\epsilon$  that requires

$$r = O\left(\sqrt{\frac{1+6c_0}{\epsilon}} (\|\mathcal{L}\|_{pauli} T)^{1.5}\right)$$
(8)

calls to oracles  $\mathcal{A}_{\delta t}^{(i)}$ , and any Hamiltonian simulation subroutine  $\mathcal{K}_{\delta t}$  where  $\delta t = T/r$ . No ancilla qubits are

needed beyond what is required for the Hamiltonian simulation subroutine  $\mathcal{K}_{\delta t}$ .

As an example, consider the case of a Lindbladian  $\mathcal{L}_{\gamma}$ that is a sum of an arbitrary Hamiltonian part  $\mathcal{H}$  and a dissipator  $\mathcal{D}_{\gamma}$  which generates the global depolarization channel with rate  $\gamma$ . Applying Theorem 1 gives us the total cost to simulate the dynamics described by  $\mathcal{L}_{\gamma}$  to be  $O\left(n\frac{((\gamma+||\mathcal{H}||_{pauli})T)^{1.5}}{\sqrt{\epsilon}}\right)$  gates along with  $\tilde{O}\left(\log(T/\epsilon)\right)$ ancilla if choosing to use the Hamiltonian simulation subroutine of [7]. As another example, consider the case when  $\mathcal{L}_{\Gamma}$  generates 1-local dephasing noise. In this case, the jump operators have the form  $L_{\mu} = \sqrt{\frac{\Gamma}{2}}Z_{\mu}$  where  $Z_{\mu}$ acts on the  $\mu$ -th qubit. The analysis follows similar to the above with  $\gamma$  replaced by  $n\Gamma/2$ . For details of both calculations see the SM.

Time-dependent Lindblad equation.—The algorithm and analysis above can be generalized to include time-dependent Lindblad superoperators with a timedependent dissipative portion  $\mathcal{D}(t)$ . If the dissipator generates a channel that is approximately stochastically simulatable at all times, i.e.,

$$\mathcal{T}e^{\int_{t}^{t+\delta t}\mathcal{D}(t')dt'}(\rho(t)) = \mathcal{N}_{t,\delta t}(\rho(t)) + \mathcal{O}(\delta t^{3}), \quad (9)$$

holds for all t, then the algorithm can be easily modified to simulate such systems. To do so we leverage Theorem 2 to divide the time-dependent dynamics into its time-dependent dissipator and its Hamiltonian part.

**Theorem 2.** Let  $\mathcal{H}$  and  $\mathcal{D}(t)$  be Lindbladians and  $0 \leq \left(\frac{\|\mathcal{H}\|_{\diamond}}{2} + \sup_{t} \|\mathcal{D}(t)\|_{\diamond}\right) \delta t \leq 1$ , then  $\left\|\mathcal{T}e^{\int_{t}^{t+\delta t} (\mathcal{H}+\mathcal{D}(t'))dt'} - e^{\frac{\delta t}{2}\mathcal{H}} \circ \mathcal{T}e^{\int_{t}^{t+\delta t} \mathcal{D}(t')dt'} \circ e^{\frac{\delta t}{2}\mathcal{H}}\right\|_{\diamond}$  $\leq \frac{\sup_{t} \|[\mathcal{H},\mathcal{D}(t)]\|_{\diamond}}{3} \left(\frac{\|\mathcal{H}\|_{\diamond}}{2} \sup_{t} \|\mathcal{D}(t)\|_{\diamond}\right) \delta t^{3}. \quad (10)$ 

*Proof.* See Supplementary Material.

Similar to the time-independent case, we implement  
subroutines to approximate the dynamics generated by  
these two generators. The only difference lies in how  
we implement the dissipative subroutine. In the time-  
dependent case, we implement the stochastically simu-  
latable channels 
$$\mathcal{N}_{t,\delta t}$$
 as our subroutine approximating  
the dissipative dynamics. Since  $\mathcal{N}_{t,\delta t}$  explicitly depends  
on time, we will implement different stochastically sim-  
ulatable channels at each time step t where we require a  
dissipative subroutine. The rest of the analysis of the al-  
gorithm is similar to the time-independent case. The to-  
tal costs as shown above hold in the time-dependent sce-  
nario with the only difference being, replacing  $\|\mathcal{L}\|_{pauli}$   
with  $\sup_{t} \|\mathcal{L}(t)\|_{pauli}$  and  $c_0$  with  $\sup_{t} c_0(t)$  in Theorem 1.

Generalized noise-model by allowing ancilla qubits.— At the expense of adding ancilla qubits and applying unitary operations on the joint system, one can extend the scope of the proposed method to simulate a larger family of noise models. The Stinespring dilation theorem guarantees that any CPTP map acting on  $2^l \times 2^l$  density operators can be implemented by adding 2l ancilla qubits and performing a (generally complicated) unitary operation on the joint system [30]. However, the probabilistic implementation of channels can reduce this ancilla requirement.

**Remark 1.** The algorithm can implement any CPTP map acting on  $2^l \times 2^l$  density operators using at most l ancilla qubits.

This observation follows from the fact that any such a map can be expressed as a convex combination of extremal channels with each extremal channel only having at most  $2^l$  many Kraus operators [31]. Therefore implementation of dilatation of any of the extremal channels requires at most l ancilla qubits. Given that only one extremal channel needs to be implemented in each compilation, at most l ancilla suffices in each run. The ancilla qubits can be reset after the application of the channel.

Simulation of local noise, naturally arising in many physical systems, is of particular interest. A local (but possibly correlated) noise model can be described by a CPTP map,

$$\mathcal{E}(\rho) = \sum_{i} \lambda_i \mathcal{G}_0^{(i)} \otimes \dots \otimes \mathcal{G}_n^{(i)}(\rho), \qquad (11)$$

where each  $\mathcal{G}_{j}^{(i)}$  acts on the *j*th qubit, with l = 1. If each  $\mathcal{G}_{j}^{(i)}$  is unital then we can expand each operation in terms of a convex combination of single-qubit unitaries. This gives us a description of the operation that satisfies Definition 1 where the  $U_{i}(t)$  operations are *n*-fold tensor products of single-qubit unitaries, thus efficiently implementable. If  $\mathcal{G}_{j}^{(i)}$  are not unital, for example such as amplitude damping, then we only need one ancilla rather than two, to implement each of the local maps. Therefore the full noisy process  $\mathcal{E}(\rho)$  can be simulated by adding at most *n* extra ancilla qubits and 2-qubit gates, which is less than the 2*n* ancilla needed if we chose to directly dilate.

Incorporating time-correlations.—As discussed before, to simulate the Markovian master equation, we implement each dissipation block of  $\mathcal{N}_{t,\delta t}$  by generating samples independent from the other blocks. However, it is straightforward to modify the algorithm to simulate dynamics that have correlations in time by simply introducing correlations in the sampling of dissipation blocks used in the compilation. In particular, the probabilities and operations in equations (3) and (4) can be generalized to define joint probabilities and operations over multiple time steps. Therefore, the domain of master equations simulable by the presented algorithm goes beyond the Markovian master equation we focused on in this work.

Discussions.—We have presented a novel quantum algorithm for simulating restricted, but physically motivated, types of dynamics generated by the Lindblad master equations. Our algorithm leverages classical randomness in the compilation phase of the quantum circuit to circumvent the overhead of deterministically implementing all of the jump operators needed to simulate the dynamics. Our approach eliminates the explicit scaling on the number of jump operators as it appears in previous algorithms, with the only scaling depending on the norm of the Lindblad superoperator, which all other Lindblad simulation circuit scalings depend on. This strategy also has the benefit of reducing ancilla costs since the only ancilla requirements come from the choice of Hamiltonian simulation subroutine. We also treat the closed system dynamics on a different footing than the dissipative dynamics. This approach allows us to leverage the wealth of available closed-system quantum algorithms in addition to extending the algorithm to deal with scenarios where dissipation may be time-dependent or correlated over time.

It would be interesting to see if our approach of leveraging classical randomness and treating the dissipative evolution differently than the closed system evolution can be used to achieve better scaling with respect to T and  $\epsilon$ , ideally  $O(T \log(\frac{1}{\epsilon}))$  of [20] but without the dependence on the number of jump operators and using only a few ancillary qubits. Extending the algorithm to incorporate more general non-Markovian dynamics is another interesting future direction.

### TIME-DEPENDENT SECOND ORDER PRODUCT FORMULA

In this section, we prove a time-dependent second-order product formula bound for Liouvillians. For simplicity, we assume that the Liouvillian  $\mathcal{L}$  splits up into a time-independent component  $\mathcal{H}$  and a time-dependent component  $\mathcal{D}(t)$ . This bound is used in the main text when generalizing our algorithm to incorporate time-dependent dissipators.

Before proving the main result we cite an important Lemma from Kliesch et al. [12] that will be useful in the proof.

**Lemma 3** (Backward time evolution [12]). Let  $\mathcal{L}$  be a Liouvillian. For t > s:

1.  $T_{\mathcal{L}}(t,s) = \mathcal{T}e^{\int_{s}^{t} \mathcal{L}(t')dt'}$  is invertible and its inverse is  $T_{\mathcal{L}}^{-}(t,s)$  as defined by

$$\partial_t T_{\mathcal{L}}^-(t,s) = -T_{\mathcal{L}}^-(t,s)\mathcal{L}$$
(S1)

2. If the Liouvillian  $\mathcal{L}$  is piecewise continuous in time then

$$\left\|T_{\mathcal{L}}^{-}(t,s)\right\|_{\diamond} \le e^{\int_{s}^{t} \left\|\mathcal{L}(t')\right\|_{\diamond} dt'} \tag{S2}$$

*Proof.* See [12].

We now prove the main result.

**Theorem** (3). (restated.) Let  $\mathcal{H}$  and  $\mathcal{D}(t)$  be Liouvillians and  $0 \leq \left(\frac{\|\mathcal{H}\|_{\diamond}}{2} + \sup_{t} \|\mathcal{D}(t)\|_{\diamond}\right)(t-s) \leq 1$ , then

$$\left\| \mathcal{T}e^{\int_{s}^{t}(\mathcal{H}+\mathcal{D}(t'))dt'} - e^{\frac{(t-s)}{2}\mathcal{H}} \circ \mathcal{T}e^{\int_{s}^{t}\mathcal{D}(t')dt'} \circ e^{\frac{(t-s)}{2}\mathcal{H}} \right\|_{\diamond} \leq \frac{\sup_{t} \left\| [\mathcal{H},\mathcal{D}(t)] \right\|_{\diamond}}{3} \left( \frac{\|\mathcal{H}\|_{\diamond}}{2} + \sup_{t} \|\mathcal{D}(t)\|_{\diamond} \right) (t-s)^{3}.$$
(S3)

*Proof.* Define  $T_{\mathcal{L}}(t,s) = \mathcal{T}e^{\int_s^t \mathcal{L}(t')dt'}$  and  $T_{\mathcal{L}}^-(t,s)$  according to Lemma 3. Both  $T_{\mathcal{L}}(t,s)$  and  $T_{\mathcal{L}}^-(t,s)$  are the unique solutions to the differential equations

$$\partial_t T_{\mathcal{L}}(t,s) = \mathcal{L}(t) T_{\mathcal{L}}(t,s) \text{ and } \partial_t T_{\mathcal{L}}^-(t,s) = -T_{\mathcal{L}}^-(t,s) \mathcal{L}(t)$$
 (S4)

with the initial condition  $T_{\mathcal{L}}(s,s) = T_{\mathcal{L}}^{-}(s,s) = \mathcal{I}$ . Rewriting the left hand side of equation (S3) in terms of our definitions gives

$$\epsilon = \left\| T_{\mathcal{H}+\mathcal{D}}(t,s) - T_{\mathcal{H}}\left(t,\frac{t+s}{2}\right) T_{\mathcal{D}}(t,s) T_{\mathcal{H}}\left(\frac{t+s}{2},s\right) \right\|_{\diamond},\tag{S5}$$

which can be rewritten as

$$\epsilon = \left\| T_{\mathcal{H}}\left(t, \frac{t+s}{2}\right) T_{\mathcal{D}}(t,s) T_{\mathcal{H}}\left(\frac{t+s}{2}, s\right) \left( T_{\mathcal{H}}^{-}\left(\frac{t+s}{2}, s\right) T_{\mathcal{D}}^{-}(t,s) T_{\mathcal{H}}^{-}\left(t, \frac{t+s}{2}\right) T_{\mathcal{H}+\mathcal{D}}(t,s) - \mathcal{I} \right) \right\|_{\diamond}$$
(S6)  
$$= \left\| T_{\mathcal{H}}\left(t, \frac{t+s}{2}\right) T_{\mathcal{D}}(t,s) T_{\mathcal{H}}\left(\frac{t+s}{2}, s\right) F(t,s) \right\|_{\diamond}$$
(S7)

where we have defined  $F(t,s) = T_{\mathcal{H}}^{-}(\frac{t+s}{2},s) T_{\mathcal{D}}^{-}(t,s) T_{\mathcal{H}}^{-}(t,\frac{t+s}{2}) T_{\mathcal{H}+\mathcal{D}}(t,s) - \mathcal{I}$ . Focusing on F(t,s) and using the fundamental theorem of calculus one finds:

$$F(t,s) = \int_{s}^{t} \partial_{r} \left( T_{\mathcal{H}}^{-} \left( \frac{r+s}{2}, s \right) T_{\mathcal{D}}^{-}(r, s) T_{\mathcal{H}}^{-} \left( r, \frac{r+s}{2} \right) T_{\mathcal{H}+\mathcal{D}}(r, s) \right) dr$$

$$= \int_{s}^{t} \left\{ \partial_{r} \left[ T_{\mathcal{H}}^{-} \left( \frac{r+s}{2}, s \right) \right] T_{\mathcal{D}}^{-}(r, s) T_{\mathcal{H}}^{-} \left( r, \frac{r+s}{2} \right) T_{\mathcal{H}+\mathcal{D}}(r, s)$$

$$+ T_{\mathcal{H}}^{-} \left( \frac{r+s}{2}, s \right) \partial_{r} \left[ T_{\mathcal{D}}^{-}(r, s) \right] T_{\mathcal{H}}^{-} \left( r, \frac{r+s}{2} \right) T_{\mathcal{H}+\mathcal{D}}(r, s)$$

$$+ T_{\mathcal{H}}^{-} \left( \frac{r+s}{2}, s \right) T_{\mathcal{D}}^{-}(r, s) \partial_{r} \left[ T_{\mathcal{H}}^{-} \left( r, \frac{r+s}{2} \right) \right] T_{\mathcal{H}+\mathcal{D}}(r, s)$$

$$+ T_{\mathcal{H}}^{-} \left( \frac{r+s}{2}, s \right) T_{\mathcal{D}}^{-}(r, s) T_{\mathcal{H}}^{-} \left( r, \frac{r+s}{2} \right) \partial_{r} \left[ T_{\mathcal{H}+\mathcal{D}}(r, s) \right] \right\} dr.$$
(S8)

Applying identities:  $\partial_t T_{\mathcal{H}+\mathcal{D}}(t,s) = (\mathcal{H}+\mathcal{D}(t))T_{\mathcal{H}+\mathcal{D}}(t,s), \ \partial_t T_{\mathcal{H}}^-\left(\frac{t+s}{2},s\right) = -\frac{1}{2}T_{\mathcal{H}}^-\left(\frac{t+s}{2},s\right)\mathcal{H}, \ \partial_t T_{\mathcal{H}}^-\left(t,\frac{t+s}{2}\right) = -\frac{1}{2}T_{\mathcal{H}}^-\left(t,\frac{t+s}{2}\right)\mathcal{H}, \ \text{and} \ \partial_t T_{\mathcal{D}}^-(t,s) = -T_{\mathcal{D}}^-(t,s)\mathcal{D}(t) \text{ yields},$ 

$$F(t,s) = \int_{s}^{t} T_{\mathcal{H}}^{-} \left(\frac{r+s}{2}, s\right) \left\{ -\frac{\mathcal{H}}{2} T_{\mathcal{D}}^{-}(r,s) T_{\mathcal{H}}^{-} \left(r, \frac{r+s}{2}\right) - T_{\mathcal{D}}^{-}(r,s) \mathcal{D}(r) T_{\mathcal{H}}^{-} \left(\frac{r+s}{2}, s\right) - T_{\mathcal{D}}^{-}(r,s) T_{\mathcal{H}}^{-} \left(r, \frac{r+s}{2}\right) \frac{\mathcal{H}}{2} + T_{\mathcal{D}}^{-}(r,s) T_{\mathcal{H}}^{-} \left(r, \frac{r+s}{2}\right) \left(\mathcal{H} + \mathcal{D}(r)\right) \right\} T_{\mathcal{H} + \mathcal{D}}(r,s) dr$$

$$= \int_{s}^{t} T_{\mathcal{H}}^{-} \left(\frac{r+s}{2}, s\right) \left\{ -\frac{\mathcal{H}}{2} T_{\mathcal{D}}^{-}(r,s) T_{\mathcal{H}}^{-} \left(r, \frac{r+s}{2}\right) - T_{\mathcal{D}}^{-}(r,s) \mathcal{D}(r) T_{\mathcal{H}}^{-} \left(\frac{r+s}{2}, s\right) + T_{\mathcal{D}}^{-}(r,s) \mathcal{T}_{\mathcal{H}}^{-} \left(r, \frac{r+s}{2}\right) \left(\frac{\mathcal{H}}{2} + \mathcal{D}(r)\right) \right\} T_{\mathcal{H} + \mathcal{D}}(r,s) dr$$

$$= -\int_{s}^{t} T_{\mathcal{H}}^{-} \left(\frac{r+s}{2}, s\right) \left\{ \left[ T_{\mathcal{D}}^{-}(r,s), \mathcal{D}(r) \right] T_{\mathcal{H}}^{-} \left(\frac{r+s}{2}, s\right) + \left[ \frac{\mathcal{H}}{2} + \mathcal{D}(r), T_{\mathcal{D}}^{-}(r,s) T_{\mathcal{H}}^{-} \left(r, \frac{r+s}{2}\right) \right] \right\} T_{\mathcal{H} + \mathcal{D}}(r,s) dr. \tag{S9}$$

Applying the fundamental theorem of calculus to the terms inside each of the commutators and using the above derivative identities again yields,

$$\begin{split} F(t,s) &= -\int_{s}^{t} T_{\mathcal{H}}^{-} \left(\frac{r+s}{2}, s\right) \int_{s}^{r} \left\{ \partial_{u} \left( \left[ T_{\mathcal{D}}^{-}(u,s), \mathcal{D}(r) \right] T_{\mathcal{H}}^{-} \left( \frac{u+s}{2}, s \right) \right) \\ &+ \partial_{u} \left( \left[ \frac{\mathcal{H}}{2} + \mathcal{D}(r), T_{\mathcal{D}}^{-}(u,s) T_{\mathcal{H}}^{-} \left( u, \frac{u+s}{2} \right) \right] \right) \right\} T_{\mathcal{H} + \mathcal{D}}(r,s) du dr \\ &= -\int_{s}^{t} T_{\mathcal{H}}^{-} \left( \frac{r+s}{2}, s \right) \int_{s}^{r} \left\{ \left[ \partial_{u} \left[ T_{\mathcal{D}}^{-}(u,s) \right], \mathcal{D}(r) \right] T_{\mathcal{H}}^{-} \left( \frac{u+s}{2}, s \right) \right. \\ &+ \left[ T_{\mathcal{D}}^{-}(u,s), \mathcal{D}(r) \right] \partial_{u} \left[ T_{\mathcal{H}}^{-} \left( \frac{u+s}{2}, s \right) \right] \\ &+ \left[ \frac{\mathcal{H}}{2} + \mathcal{D}(r), \partial_{u} \left[ T_{\mathcal{D}}^{-}(u,s) \right] T_{\mathcal{H}}^{-} \left( u, \frac{u+s}{2} \right) + T_{\mathcal{D}}^{-}(u,s) \partial_{u} \left[ T_{\mathcal{H}}^{-} \left( u, \frac{u+s}{2} \right) \right] \right] \right\} T_{\mathcal{H} + \mathcal{D}}(r,s) du dr \\ &= \int_{s}^{t} T_{\mathcal{H}}^{-} \left( \frac{r+s}{2}, s \right) \int_{s}^{r} \left\{ \left[ T_{\mathcal{D}}^{-}(u,s) \mathcal{D}(u), \mathcal{D}(r) \right] T_{\mathcal{H}}^{-} \left( \frac{u+s}{2}, s \right) + \left[ T_{\mathcal{D}}^{-}(u,s), \mathcal{D}(r) \right] T_{\mathcal{H}}^{-} \left( \frac{u+s}{2}, s \right) \frac{\mathcal{H}}{2} \\ &+ \left[ \frac{\mathcal{H}}{2} + \mathcal{D}(r), T_{\mathcal{D}}^{-}(u,s) \mathcal{D}(u) T_{\mathcal{H}}^{-} \left( u, \frac{u+s}{2} \right) + T_{\mathcal{D}}^{-}(u,s) T_{\mathcal{H}}^{-} \left( u, \frac{u+s}{2} \right) \frac{\mathcal{H}}{2} \right] \right\} T_{\mathcal{H} + \mathcal{D}}(r,s) du dr \\ &= \int_{s}^{t} \int_{s}^{r} T_{\mathcal{H}}^{-} \left( \frac{r+s}{2}, s \right) \left\{ T_{\mathcal{D}}^{-}(u,s) \left[ \mathcal{D}(u), \mathcal{D}(r) \right] T_{\mathcal{H}}^{-} \left( \frac{u+s}{2}, s \right) + \left[ T_{\mathcal{D}}^{-}(u,s), \mathcal{D}(r) \right] \mathcal{D}(u) T_{\mathcal{H}}^{-} \left( \frac{u+s}{2}, s \right) \\ &+ \left[ T_{\mathcal{D}}^{-}(u,s), \mathcal{D}(r) \right] \frac{\mathcal{H}}{2} T_{\mathcal{H}}^{-} \left( \frac{u+s}{2}, s \right) \\ &+ \left[ T_{\mathcal{D}}^{-}(u,s), \mathcal{D}(r) \right] \frac{\mathcal{H}}{2} T_{\mathcal{H}}^{-} \left( \frac{u+s}{2}, s \right) \\ &+ \left[ \frac{\mathcal{H}}{2} + \mathcal{D}(r), T_{\mathcal{D}}^{-}(u,s) \left( \frac{\mathcal{H}}{2} + \mathcal{D}(u) \right) T_{\mathcal{H}}^{-} \left( u, \frac{u+s}{2} \right) \right] \right\} T_{\mathcal{H} + \mathcal{D}}(r,s) du dr,$$
 (S10)

where the last equality follows from commuting  $T_{\mathcal{H}}^-$  and  $\mathcal{H}$  since  $\mathcal{H}$  is time-independent. Massaging the last commutator

in the sum yields,

$$F(t,s) = \int_{s}^{t} \int_{s}^{r} T_{\mathcal{H}}^{-} \left(\frac{r+s}{2}, s\right) \left\{ T_{\mathcal{D}}^{-}(u,s) \left[\mathcal{D}(u), \mathcal{D}(r)\right] T_{\mathcal{H}}^{-} \left(\frac{u+s}{2}, s\right) + \left[T_{\mathcal{D}}^{-}(u,s), \mathcal{D}(r)\right] \mathcal{D}(u) T_{\mathcal{H}}^{-} \left(\frac{u+s}{2}, s\right) \right. \\ \left. + \left[T_{\mathcal{D}}^{-}(u,s), \mathcal{D}(r)\right] \frac{\mathcal{H}}{2} T_{\mathcal{H}}^{-} \left(\frac{u+s}{2}, s\right) \right. \\ \left. + T_{\mathcal{D}}^{-}(u,s) \left(\frac{\mathcal{H}}{2} + \mathcal{D}(u)\right) \left[\mathcal{D}(r), T_{\mathcal{H}}^{-} \left(u, \frac{u+s}{2}\right)\right] \right] \\ \left. + T_{\mathcal{D}}^{-}(u,s) \left[\frac{\mathcal{H}}{2}, \mathcal{D}(u)\right] T_{\mathcal{H}}^{-} \left(u, \frac{u+s}{2}\right) + T_{\mathcal{D}}^{-}(u,s) \left[\mathcal{D}(r), \frac{\mathcal{H}}{2}\right] T_{\mathcal{H}}^{-} \left(u, \frac{u+s}{2}\right) \right. \\ \left. + T_{\mathcal{D}}^{-}(u,s) \left[\mathcal{D}(r), \mathcal{D}(u)\right] T_{\mathcal{H}}^{-} \left(u, \frac{u+s}{2}\right) \\ \left. + \left[\frac{\mathcal{H}}{2}, T_{\mathcal{D}}^{-}(u,s)\right] \left(\frac{\mathcal{H}}{2} + \mathcal{D}(u)\right) T_{\mathcal{H}}^{-} \left(u, \frac{u+s}{2}\right) \right] \right. \\ \left. + \left[\mathcal{D}(r), T_{\mathcal{D}}^{-}(u,s)\right] \left(\frac{\mathcal{H}}{2} + \mathcal{D}(u)\right) T_{\mathcal{H}}^{-} \left(u, \frac{u+s}{2}\right) \right\} T_{\mathcal{H}+\mathcal{D}}(r,s) du dr.$$

$$\tag{S11}$$

Simplifying the equation gives us,

$$F(t,s) = \int_{s}^{t} \int_{s}^{r} T_{\mathcal{H}}^{-} \left(\frac{r+s}{2}, s\right) \left\{ -T_{\mathcal{D}}^{-}(u,s) \left(\frac{\mathcal{H}}{2} + \mathcal{D}(u)\right) \left[T_{\mathcal{H}}^{-} \left(u, \frac{u+s}{2}\right), \mathcal{D}(r)\right] \right. \\ \left. - \left[T_{\mathcal{D}}^{-}(u,s), \frac{\mathcal{H}}{2}\right] \left(\frac{\mathcal{H}}{2} + \mathcal{D}(u)\right) T_{\mathcal{H}}^{-} \left(u, \frac{u+s}{2}\right) \right. \\ \left. + T_{\mathcal{D}}^{-}(u,s) \left[\frac{\mathcal{H}}{2}, \mathcal{D}(u) - \mathcal{D}(r)\right] T_{\mathcal{H}}^{-} \left(u, \frac{u+s}{2}\right) \right\} T_{\mathcal{H}+\mathcal{D}}(r,s) du dr \\ \left. = \int_{s}^{t} \int_{s}^{r} T_{\mathcal{H}}^{-} \left(\frac{r+s}{2}, s\right) \left\{ -T_{\mathcal{D}}^{-}(u,s) \left(\frac{\mathcal{H}}{2} + \mathcal{D}(u)\right) \left(\int_{s}^{u} \partial_{v} \left[T_{\mathcal{H}}^{-} \left(v, \frac{v+s}{2}\right) \mathcal{D}(r) T_{\mathcal{H}} \left(v, \frac{v+s}{2}\right)\right] dv \right) T_{\mathcal{H}}^{-} \left(u, \frac{u+s}{2}\right) \\ \left. - \left(\int_{s}^{u} \partial_{v} \left[T_{\mathcal{D}}^{-}(v,s) \frac{\mathcal{H}}{2} T_{\mathcal{D}}(v,s)\right] dv \right) T_{\mathcal{D}}^{-}(u,s) \left(\frac{\mathcal{H}}{2} + \mathcal{D}(u)\right) T_{\mathcal{H}}^{-} \left(u, \frac{u+s}{2}\right) \\ \left. + T_{\mathcal{D}}^{-}(u,s) \left[\frac{\mathcal{H}}{2}, \int_{r}^{u} \partial_{v} \mathcal{D}(v) dv\right] T_{\mathcal{H}}^{-} \left(u, \frac{u+s}{2}\right) \right] \right\} T_{\mathcal{H}+\mathcal{D}}(r,s) du dr.$$
(S12)

Applying the fundamental theorem of calculus again yields

$$F(t,s) = \int_{s}^{t} \int_{s}^{r} T_{\mathcal{H}}^{-} \left(\frac{r+s}{2}, s\right) \left\{ -T_{\mathcal{D}}^{-}(u,s) \left(\frac{\mathcal{H}}{2} + \mathcal{D}(u)\right) \left(\int_{s}^{u} \partial_{v} \left[T_{\mathcal{H}}^{-} \left(v, \frac{v+s}{2}\right) \mathcal{D}(r) T_{\mathcal{H}} \left(v, \frac{v+s}{2}\right)\right] dv \right) T_{\mathcal{H}}^{-} \left(u, \frac{u+s}{2}\right) - \left(\int_{s}^{u} \partial_{v} \left[T_{\mathcal{D}}^{-}(v,s) \frac{\mathcal{H}}{2} T_{\mathcal{D}}(v,s)\right] dv \right) T_{\mathcal{D}}^{-}(u,s) \left(\frac{\mathcal{H}}{2} + \mathcal{D}(u)\right) T_{\mathcal{H}}^{-} \left(u, \frac{u+s}{2}\right) + T_{\mathcal{D}}^{-}(u,s) \left[\frac{\mathcal{H}}{2}, \int_{r}^{u} \partial_{v} \mathcal{D}(v) dv\right] T_{\mathcal{H}}^{-} \left(u, \frac{u+s}{2}\right) \right\} T_{\mathcal{H}+\mathcal{D}}(r,s) du dr.$$
(S13)

Continuing to simplify our expression for F(t,s) gives us

$$\begin{split} F(t,s) &= \int_{s}^{t} \int_{s}^{r} T_{\mathcal{H}}^{-} \left( \frac{r+s}{2}, s \right) \Big\{ \\ &\int_{s}^{u} T_{\mathcal{D}}^{-}(u,s) \left( \frac{\mathcal{H}}{2} + \mathcal{D}(u) \right) T_{\mathcal{H}}^{-} \left( v, \frac{v+s}{2} \right) \left[ \frac{\mathcal{H}}{2}, \mathcal{D}(r) \right] T_{\mathcal{H}} \left( v, \frac{v+s}{2} \right) T_{\mathcal{H}}^{-} \left( u, \frac{u+s}{2} \right) dv \\ &+ \int_{s}^{u} T_{\mathcal{D}}^{-}(v,s) \left[ \mathcal{D}(v), \frac{\mathcal{H}}{2} \right] T_{\mathcal{D}}(v,s) T_{\mathcal{D}}^{-}(u,s) \left( \frac{\mathcal{H}}{2} + \mathcal{D}(u) \right) T_{\mathcal{H}}^{-} \left( u, \frac{u+s}{2} \right) dv \\ &+ \int_{r}^{u} T_{\mathcal{D}}^{-}(u,s) \left[ \frac{\mathcal{H}}{2}, \partial_{v} \mathcal{D}(v) \right] T_{\mathcal{H}}^{-} \left( u, \frac{u+s}{2} \right) dv \\ &\} T_{\mathcal{H} + \mathcal{D}}(r,s) du dr \\ &= \int_{s}^{t} \int_{s}^{r} T_{\mathcal{H}}^{-} \left( \frac{r+s}{2}, s \right) \Big\{ \\ &\int_{s}^{u} T_{\mathcal{D}}^{-}(u,s) \left( \frac{\mathcal{H}}{2} + \mathcal{D}(u) \right) T_{\mathcal{H}}^{-} \left( v, \frac{v+s}{2} \right) \left[ \frac{\mathcal{H}}{2}, \mathcal{D}(r) \right] T_{\mathcal{H}}^{-} \left( \frac{u+s}{2}, \frac{v+s}{2} \right) dv \\ &+ \int_{s}^{u} T_{\mathcal{D}}^{-}(v,s) \left[ \mathcal{D}(v), \frac{\mathcal{H}}{2} \right] T_{\mathcal{D}}^{-}(u,v) \left( \frac{\mathcal{H}}{2} + \mathcal{D}(u) \right) T_{\mathcal{H}}^{-} \left( u, \frac{u+s}{2} \right) dv \\ &+ \int_{r}^{u} T_{\mathcal{D}}^{-}(u,s) \left[ \mathcal{D}(v), \frac{\mathcal{H}}{2} \right] T_{\mathcal{D}}^{-}(u,v) \left( \frac{\mathcal{H}}{2} + \mathcal{D}(u) \right) T_{\mathcal{H}}^{-} \left( u, \frac{u+s}{2} \right) dv \\ &+ \int_{r}^{u} T_{\mathcal{D}}^{-}(u,s) \left[ \frac{\mathcal{H}}{2}, \partial_{v} \mathcal{D}(v) \right] T_{\mathcal{H}}^{-} \left( u, \frac{u+s}{2} \right) dv \\ &+ \int_{r}^{u} T_{\mathcal{D}}^{-}(u,s) \left[ \frac{\mathcal{H}}{2}, \partial_{v} \mathcal{D}(v) \right] T_{\mathcal{H}}^{-} \left( u, \frac{u+s}{2} \right) dv \end{aligned}$$
(S14)

Returning to equation (S6) we find,

$$\begin{split} \epsilon &\leq \int_{s}^{t} \int_{s}^{r} \left\| T_{\mathcal{H}}\left(t, \frac{t+s}{2}\right) T_{\mathcal{D}}\left(t, s\right) T_{\mathcal{H}}\left(\frac{t+s}{2}, \frac{r+s}{2}\right) \right\|_{\diamond} \left\{ \\ &\int_{s}^{u} \left\| T_{\mathcal{D}}^{-}\left(u, s\right) \left(\frac{\mathcal{H}}{2} + \mathcal{D}(u)\right) T_{\mathcal{H}}^{-}\left(v, \frac{v+s}{2}\right) \left[\frac{\mathcal{H}}{2}, \mathcal{D}(r)\right] T_{\mathcal{H}}^{-}\left(\frac{u+s}{2}, \frac{v+s}{2}\right) \right\|_{\diamond} dv \\ &+ \int_{s}^{u} \left\| T_{\mathcal{D}}^{-}\left(v, s\right) \left[\mathcal{D}(v), \frac{\mathcal{H}}{2}\right] T_{\mathcal{D}}^{-}\left(u, v\right) \left(\frac{\mathcal{H}}{2} + \mathcal{D}(u)\right) T_{\mathcal{H}}^{-}\left(u, \frac{u+s}{2}\right) \right\|_{\diamond} dv \\ &+ \int_{r}^{u} \left\| T_{\mathcal{D}}^{-}\left(u, s\right) \left[\frac{\mathcal{H}}{2}, \partial_{v} \mathcal{D}(v)\right] T_{\mathcal{H}}^{-}\left(u, \frac{u+s}{2}\right) \right\|_{\diamond} dv \\ &\leq \int_{s}^{t} \int_{s}^{r} \left\{ \\ &\int_{s}^{u} \left\| T_{\mathcal{D}}^{-}\left(u, s\right) \right\|_{\diamond} \left\| \left(\frac{\mathcal{H}}{2} + \mathcal{D}(u)\right) \right\|_{\diamond} \left\| T_{\mathcal{H}}^{-}\left(v, \frac{v+s}{2}\right) \right\|_{\diamond} \left\| \left[\frac{\mathcal{H}}{2}, \mathcal{D}(r)\right] \right\|_{\diamond} \left\| T_{\mathcal{H}}^{-}\left(\frac{u+s}{2}, \frac{v+s}{2}\right) \right\|_{\diamond} dv \\ &+ \int_{s}^{u} \left\| T_{\mathcal{D}}^{-}\left(v, s\right) \right\|_{\diamond} \left\| \left[ \mathcal{D}(v), \frac{\mathcal{H}}{2} \right] \right\|_{\diamond} \left\| T_{\mathcal{D}}^{-}\left(u, v\right) \right\|_{\diamond} \left\| \left(\frac{\mathcal{H}}{2} + \mathcal{D}(u)\right) \right\|_{\diamond} \left\| T_{\mathcal{H}}^{-}\left(u, \frac{u+s}{2}\right) \right\|_{\diamond} dv \\ &+ \int_{r}^{u} \left\| T_{\mathcal{D}}^{-}\left(u, s\right) \right\|_{\diamond} \left\| \left[ \frac{\mathcal{H}}{2}, \partial_{v} \mathcal{D}(v) \right] \right\|_{\diamond} \left\| T_{\mathcal{H}}^{-}\left(u, \frac{u+s}{2}\right) \right\|_{\diamond} dv \\ &+ \int_{r}^{u} \left\| T_{\mathcal{D}}^{-}\left(u, s\right) \right\|_{\diamond} \left\| \left[ \frac{\mathcal{H}}{2}, \partial_{v} \mathcal{D}(v) \right] \right\|_{\diamond} \left\| T_{\mathcal{H}}^{-}\left(u, \frac{u+s}{2}\right) \right\|_{\diamond} dv \\ &+ \int_{r}^{u} \left\| T_{\mathcal{D}}^{-}\left(u, s\right) \right\|_{\diamond} \left\| \left[ \frac{\mathcal{H}}{2}, \partial_{v} \mathcal{D}(v) \right] \right\|_{\diamond} \left\| T_{\mathcal{H}}^{-}\left(u, \frac{u+s}{2}\right) \right\|_{\diamond} dv \end{aligned}$$

$$(S15)$$

where the second inequality follows from  $||T_{\mathcal{L}}(t,s)||_{\diamond} = 1$  since  $T_{\mathcal{L}}(t,s)$  is a CPTP map. Applying part 2 of Lemma 3

yields,

$$\begin{aligned} \epsilon &\leq \int_{s}^{t} \int_{s}^{r} \left\{ \int_{s}^{u} e^{\frac{\|\mathcal{H}\|_{0}}{2}(u-s) + \int_{s}^{u} \|\mathcal{D}(t')\|_{\diamond} dt'} \left\| \left[ \mathcal{D}(v), \frac{\mathcal{H}}{2} \right] \right\|_{\diamond} \left\| \left( \frac{\mathcal{H}}{2} + \mathcal{D}(u) \right) \right\|_{\diamond} \left\| \left[ \frac{\mathcal{H}}{2}, \mathcal{D}(r) \right] \right\|_{\diamond} dv \\ &+ \int_{s}^{u} e^{\frac{\|\mathcal{H}\|_{0}}{2}(u-s) + \int_{s}^{u} \|\mathcal{D}(t')\|_{\diamond} dt'} \left\| \left[ \mathcal{D}(v), \frac{\mathcal{H}}{2} \right] \right\|_{\diamond} \left\| \left( \frac{\mathcal{H}}{2} + \mathcal{D}(u) \right) \right\|_{\diamond} dv \\ &+ \int_{r}^{u} e^{\frac{\|\mathcal{H}\|_{0}}{2}(u-s) + \int_{s}^{u} \|\mathcal{D}(t')\|_{\diamond} dt'} \left\| \left[ \frac{\mathcal{H}}{2}, \partial_{v} \mathcal{D}(v) \right] \right\|_{\diamond} dv \right\} du dr \\ &\leq \int_{s}^{t} \int_{s}^{r} e^{\left( \frac{\|\mathcal{H}\|_{0}}{2} + \sup_{t} \|\mathcal{D}(t)\|_{\diamond} \right)(u-s)} \left\{ \int_{s}^{u} \left\| \left( \frac{\mathcal{H}}{2} + \mathcal{D}(u) \right) \right\|_{\diamond} \left\| \left[ \frac{\mathcal{H}}{2}, \mathcal{D}(r) \right] \right\|_{\diamond} dv \\ &+ \int_{s}^{u} \left\| \left[ \mathcal{D}(v), \frac{\mathcal{H}}{2} \right] \right\|_{\diamond} \left\| \left( \frac{\mathcal{H}}{2} + \mathcal{D}(u) \right) \right\|_{\diamond} dv \\ &+ \int_{s}^{t} \left\| \left[ \mathcal{D}(v), \frac{\mathcal{H}}{2} \right] \right\|_{\diamond} dv \right\} du dr \\ &\leq \int_{s}^{t} \int_{s}^{r} e^{\left( \frac{\|\mathcal{H}\|_{0}}{2} + \sup_{t} \|\mathcal{D}(t)\|_{\diamond} \right)(u-s)} \left\{ \left( \frac{\|\mathcal{H}\|_{\diamond}}{2} + \sup_{t} \|\mathcal{D}(t)\|_{\diamond} \right) \sup_{t} \left\| [\mathcal{H}, \mathcal{D}(t)] \right\|_{\diamond} (u-s) \\ &+ \sup_{t} \left\| \left[ \frac{\mathcal{H}}{2}, \partial_{t} \mathcal{D}(t) \right] \right\|_{\diamond} ((u-s) - (r-s)) \right\} du dr. \end{aligned}$$
(S16)

Defining  $L = \frac{\|\mathcal{H}\|_{\diamond}}{2} + \sup_{t} \|\mathcal{D}(t)\|_{\diamond}, C = \sup_{t} \|[\mathcal{H}, \mathcal{D}(t)]\|_{\diamond}$ , and  $D = \sup_{t} \|[\mathcal{H}, \partial_{t}\mathcal{D}(t)]\|_{\diamond}$  gives us the bound,

$$\begin{aligned} \epsilon &\leq \int_{s}^{t} \int_{s}^{r} e^{L(u-s)} \left\{ \frac{2LC+D}{2}(u-s) - \frac{D}{2}(r-s) \right\} du dr \\ &\leq \int_{s}^{t} \left\{ \frac{2LC+D}{2L^{2}} \left[ e^{L(r-s)}(L(r-s)-1) + 1 \right] - \frac{D}{2L^{2}}L(r-s) \left[ e^{L(r-s)} - 1 \right] \right\} dr \end{aligned} \tag{S17} \\ &\leq \left\{ \frac{2LC+D}{2L^{3}} \left( 2 \left( 1 - e^{L(t-s)} \right) + L(t-s) \left( 1 + e^{L(t-s)} \right) \right) - \frac{D}{2L^{3}} \left( (L(t-s)-1)e^{L(t-s)} + 1 - \frac{(L(t-s))^{2}}{2} \right) \right\}. \end{aligned}$$

Rewriting the bound we find,

$$\epsilon \leq \left\{ \frac{2LC+D}{2L^3} \left( 2\left(1-e^{L(t-s)}\right) + L(t-s)\left(1+e^{L(t-s)}\right) \right) - \frac{D}{2L^3} \left( (L(t-s)-1)e^{L(t-s)} + 1 - \frac{(L(t-s))^2}{2} \right) \right\}$$
  

$$\epsilon \leq \left\{ \frac{2LC+D}{2L^3} \left( \frac{(L(t-s))^3}{3} + \mathcal{O}\left( (L(t-s))^4 \right) \right) - \frac{D}{2L^3} \left( \frac{(L(t-s))^3}{3} + \mathcal{O}\left( (L(t-s))^4 \right) \right) \right\}$$
(S18)

Assuming  $\left(\frac{\|\mathcal{H}\|_{\diamond}}{2} + \sup_{t} \|\mathcal{D}(t)\|_{\diamond}\right)(t-s) = L(t-s) \leq 1$ , gives us

$$\epsilon \leq \frac{LC}{3}(t-s)^3 = \frac{1}{3} \sup_t \left\| \left[\mathcal{H}, \mathcal{D}(t)\right] \right\|_{\diamond} \left( \frac{\left\|\mathcal{H}\right\|_{\diamond}}{2} + \sup_t \left\|\mathcal{D}(t)\right\|_{\diamond} \right) (t-s)^3$$
(S19)

# EVOLUTION GENERATED BY UNITARY JUMP OPERATORS

Let  $\mathcal{D}$  be a Lindbladian dissipator with jump operators  $L_{\mu}$ . Setting  $L_{\mu} = \alpha_{\mu}U_{\mu}$  where  $U_{\mu}$  is unitary gives us  $\mathcal{D}(\rho) = \sum_{\mu=1}^{m} \left( L_{\mu}\rho L_{\mu}^{\dagger} - \frac{1}{2} \{ L_{\mu}^{\dagger}L_{\mu}, \rho \} \right) = \sum_{\mu=1}^{m} |\alpha_{\mu}|^2 U_{\mu}\rho U_{\mu}^{\dagger} - \sum_{\mu=1}^{m} |\alpha_{\mu}|^2 \rho$ . Define the random unitary channel  $\mathcal{R}(\rho) = \sum_{\mu=1}^{m} |\alpha_{\mu}|^2 U_{\mu}\rho U_{\mu}^{\dagger}$  and  $a = \sum_{\mu=1}^{m} |\alpha_{\mu}|^2$ , hence  $\mathcal{D}(\rho) = \mathcal{R} - a\mathcal{I}$ . Note that  $e^{\delta t\mathcal{D}} = e^{-a\delta t\mathcal{I}}e^{\delta t\mathcal{R}}$ . Assuming  $\delta t \|\mathcal{R}\|_{\diamond} \leq 1$ , we have

$$\left\| e^{\delta t \mathcal{D}} - e^{-a\delta t} \sum_{k=0}^{K} \frac{\delta t^{k}}{k!} \mathcal{R}^{k}(\rho) \right\|_{\diamond} \le c e^{-a\delta t} \frac{(\delta t \|\mathcal{R}\|_{\diamond})^{K+1}}{(K+1)!}.$$
(S20)

# COSTS FOR SIMULATING $\mathcal{L}_{\gamma}$ and $\mathcal{L}_{\Gamma}$

Consider the case of a Lindbladian  $\mathcal{L}_{\gamma}$  which generates arbitrary Hamiltonian evolution along with global depolarizing noise,

$$\mathcal{L}_{\gamma}(\rho) = \mathcal{H}(\rho) + \mathcal{D}_{\gamma}(\rho) = -i[H,\rho] + \sum_{\mu=1}^{m} \left( L_{\mu}\rho L_{\mu}^{\dagger} - \frac{1}{2} \{ L_{\mu}^{\dagger}L_{\mu}, \rho \} \right)$$
$$= -i[H,\rho] + \sum_{\mu=1}^{4^{n}-1} \frac{\gamma}{4^{n}} \left( V_{\mu}\rho V_{\mu}^{\dagger} - \frac{\gamma}{4^{n}}\rho \right)$$
(S21)

where H is an arbitrary Hamiltonian,  $\gamma \in \mathbb{R}_+$ , and  $V_{\mu} \in \{\mathbb{I}, X, Y, Z\}^{\otimes n}/\{\mathbb{I}^{\otimes n}\}$ . There are  $m = 4^n - 1$  jump operators for  $\mathcal{D}_{\gamma}$  of the form  $L_{\mu} = \sqrt{\frac{\gamma}{4^n}} V_{\mu}$ . Since  $V_{\mu}$  is unitary,  $e^{\delta t \mathcal{D}}$  is approximately stochastically simulatable up to arbitrary precision as discussed in the above section. Thus oracles  $\mathcal{A}_{\delta t}^{(i)}$  are compositions of elements in  $\{\mathbb{I}, X, Y, Z\}^{\otimes n}/\{\mathbb{I}^{\otimes n}\}$ . Calculating  $\|\mathcal{L}\|_{pauli}$  gives

$$\|\mathcal{L}\|_{pauli} = \|\mathcal{H}\|_{pauli} + \|\mathcal{D}_{\gamma}\|_{pauli} = \|\mathcal{H}\|_{pauli} + \sum_{\mu=1}^{m} \left(\sum_{k=0}^{s-1} \beta_{\mu k}\right)^{2}.$$
 (S22)

Since jump operators  $L_{\mu} = \sqrt{\frac{\gamma}{4n}} V_{\mu}$  are already in the form of  $L_{\mu} = \sum_{k=0}^{s-1} \beta_{\mu k} V_{\mu k}$  where  $\beta_{\mu k} > 0$  and  $V_{\mu k}$  is an *n*-fold tensor product of Pauli operators with arbitrary phase, we find

$$\sum_{k=0}^{s-1} \beta_{\mu k} = \sqrt{\frac{\gamma}{4^n}}.$$
(S23)

This implies

$$\|\mathcal{L}\|_{pauli} = \|\mathcal{H}\|_{pauli} + \sum_{\mu=1}^{4^n - 1} \frac{\gamma}{4^n} = \|\mathcal{H}\|_{pauli} + \left(1 - \frac{1}{4^n}\right)\gamma = O\left(\|\mathcal{H}\|_{pauli} + \gamma\right).$$
(S24)

Since oracles  $\mathcal{A}_{\delta t}^{(i)}$  are compositions of elements in  $\{\mathbb{I}, X, Y, Z\}^{\otimes n}/\{\mathbb{I}^{\otimes n}\}$ ,  $\mathcal{A}_{\delta t}^{(i)}$  are *n*-fold tensor products of singlequbit Pauli operators with arbitrary phase. Thus each  $\mathcal{A}_{\delta t}^{(i)}$  requires O(n) single-qubit gates to implement. Applying Theorem 1 gives us the total cost to simulate the dynamics described by  $\mathcal{L}_{\gamma}$  to be

$$O\left(n\frac{((\gamma + \|\mathcal{H}\|_{pauli})T)^{1.5}}{\sqrt{\epsilon}}\right)$$
(S25)

1- and 2-qubit gates along with

$$\tilde{O}\left(\log(T/\epsilon)\right)$$
 (S26)

ancilla if choosing to use the Hamiltonian simulation subroutine of [7].

As another example, consider the case when  $\mathcal{L}_{\Gamma}$  generates 1-local dephasing noise. In this case, the jump operators have the form  $L_{\mu} = \sqrt{\frac{\Gamma}{2}} Z_{\mu}$  where  $Z_{\mu}$  acts on the  $\mu$ -th qubit. The analysis follows similar to above with  $\gamma$  replaced by  $n\Gamma/2$ . Similarly, oracles  $\mathcal{A}_{\delta t}^{(i)}$  become *n*-fold tensor products of single qubit unitaries.
