

From snapping out Brownian motions to Walsh's spider processes on star-like graphs

Adam Bobrowski and Elżbieta Ratajczyk

Abstract. By analyzing matrices involved, we prove that a snapping-out Brownian motion with large permeability coefficients is a good approximation of Walsh's spider process on the star-like graph $K_{1,k}$. Thus, the latter process can be seen as a Brownian motion perturbed by a trace of semi-permeable membrane at the graph's center.

Mathematics Subject Classification (2020). 35B06, 46E05, 47D06, 47D07, 47D09.

Keywords. Walsh's spider process, snapping-out Brownian motion, skew Brownian motion, invariant subspaces, transmission conditions.

1. Introduction

1.1. Sticky snapping-out Brownian motion

Given a natural number $k \geq 2$ and non-negative parameters

$$a_i, b_i, c_i, \quad i \in \mathcal{K} := \{1, \dots, k\}$$

with $b_i > 0$, we think of the following Markov process on the compact space

$$S_k := \bigcup_{i \in \mathcal{K}} (\{i\} \times [0, \infty]).$$

While on the i th copy of $[0, \infty]$, our process is initially indistinguishable from the *sticky Brownian motion* with stickiness coefficient a_i/b_i , as described, for example, in [29] (see also [11]); in the particular case of $a_i = 0$, the sticky Brownian motion is the reflected Brownian motion. However, when the time spent at the i th copy of 0 exceeds an exponential time (independent of the Brownian motion) with parameter c_i , the process jumps to one of the points $(j, 0)$, $j \neq i$, all choices being equally likely. At the moment of jump the process forgets its past and starts to behave like a sticky Brownian motion on the j th copy of $[0, \infty]$, and so on (see Figure 1).

FIGURE 1. Sticky snapping out Brownian motion is a Feller process on k copies of $[0, \infty]$ (here $k = 3$), which on the i th copy behaves like a one-dimensional sticky Brownian motion with stickiness coefficient a_i/b_i . After spending enough time at $(0, i)$ the process jumps to one of the points $(0, j)$, $j \neq i$ to continue its motion on the corresponding copy of $[0, \infty]$, and so on. Times between jumps are governed by parameters c_i .

The so-defined process has Feller property and thus can be characterized by means of a Feller generator in $C(S_k)$, the space of continuous functions on S_k . To describe this generator, say, A_p^{s-o} (subscript p is a shorthand for the ordered set of parameters a_i, b_i, c_i described above), in detail, we introduce first the space $C[0, \infty]$ of real-valued, continuous functions f on $[0, \infty)$ such that the limits $\lim_{x \rightarrow \infty} f(x)$ exist and are finite, and note that $C(S_k)$ is isometrically isomorphic to

$$\mathfrak{F}_k := (C[0, \infty])^k,$$

the Cartesian product of k copies of $C[0, \infty]$; we identify a sequence $(f_i)_{i \in \mathcal{K}}$ with the function $f : S_k \rightarrow \mathbb{R}$ given by $f(i, x) = f_i(x)$, $i \in \mathcal{K}$, $x \in [0, \infty)$. Then, we define the domain $D(A_p^{s-o})$ of A_p^{s-o} as composed of $(f_i)_{i \in \mathcal{K}} \in \mathfrak{F}_k$ such that

- (a) each f_i is twice continuously differentiable with $f_i'' \in C[0, \infty]$,
- (b) we have

$$a_i f_i''(0) - b_i f_i'(0) = c_i \left[\frac{1}{k-1} \sum_{j \neq i} f_j(0) - f_i(0) \right], \quad i \in \mathcal{K}. \quad (1.1)$$

Moreover, for such $(f_i)_{i \in \mathcal{K}}$, we agree that $A_p^{s-o}(f_i)_{i \in \mathcal{K}} = (f_i'')_{i \in \mathcal{K}}$.

Boundary/transmission conditions of the type (1.1) have been studied and employed extensively by a number of authors in a variety of contexts (see e.g. the abundant bibliography in [9]). Among more recent literature involving relatives of (1.1), one could mention the model of inhibitory synaptic receptor dynamics of P. Bressloff [17]; see also [18], and references given in these papers. It seems that the probabilistic meaning of relations (1.1), in the case of $k = 2$, $a_1 = a_2 = 0$, has been first explained in [13], where they were put in the context of Feller boundary conditions; the subsequent [28] provides a construction of the underlying process and introduces the name *snapping-out* Brownian motion.

Our main theorem in this paper says that snapping-out Brownian motion with very large coefficients c_i can be used as an approximation for the famous Walsh's spider process.

FIGURE 2. The infinite star-like graph $K_{1,k}$ with $k = 8$ edges. Walsh's sticky process on $K_{1,k}$ is a Feller process whose behavior at the graph's center is characterized by the boundary condition visible above; outside of the center, on each of the edges, the process behaves like a standard one-dimensional Brownian motion.

1.2. Walsh's sticky process

Walsh's sticky process (a generalization of Walsh's spider process) is a Feller process on the space obtained from S_k by lumping together all the points $(i, 0) \in S_k, i \in \mathcal{K}$, that is, on the infinite metric graph $K_{1,k}$ depicted at Figure 2. The space $C(K_{1,k})$ of continuous functions on $K_{1,k}$ can be identified with the subspace

$$\mathfrak{F}_k^0 := \{(f_i)_{i \in \mathcal{K}} \in \mathfrak{F}_k \mid f_i(0) = f_j(0), i, j \in \mathcal{K}\} \subset \mathfrak{F}_k.$$

The generator, say, A_q^{SP} , of Walsh's sticky process is characterized by non-negative numbers β and $\alpha_i, i \in \mathcal{K}$ such that $\beta + \sum_{i \in \mathcal{K}} \alpha_i = 1$ — subscript q denotes the ordered set of such numbers. Namely, see [27, Thm. 2.2], we define the domain $D(A_q^{\text{SP}}) \subset \mathfrak{F}_k^0$ of A_q^{SP} as composed of $(f_i)_{i \in \mathcal{K}} \in \mathfrak{F}_k^0$ such that

- (a) each f_i is twice continuously differentiable with $f_i'' \in C[0, \infty]$,
- (b) $f_i''(0) = f_j''(0), i, j \in \mathcal{K}$,
- (c) $\beta f''(0) = \sum_{i \in \mathcal{K}} \alpha_i f'_i(0)$,

and agree that $A_q^{\text{SP}}(f_i)_{i \in \mathcal{K}} = (f_i'')_{i \in \mathcal{K}}$. Notably, by condition (b) above, $A_q^{\text{SP}} f$ belongs to \mathfrak{F}_k^0 and in particular it is meaningful to speak of $f''(0)$ for $f \in D(A_q^{\text{SP}})$, even though $f'(0)$ is not well-defined.

The related process was first introduced in the case of $k = 2$ and $\beta = 0$ by Walsh in [34] (see also [24]) under the name of *skew* Brownian motion: it differed from the standard Brownian motion on \mathbb{R} only in the fact that signs of its excursions from 0 were determined by independent Bernoulli variables. In an informal description of the process generated by A_q^{SP} in the general case of $k \geq 2$ (still with $\beta = 0$) we think of the graph as the spider's web, and of α_i as the probability that a spider passing through graph's center will continue its movement on the i th edge of the graph; β is an additional parameter (playing a similar role to a_i s of (1.1); this fact is also reflected in (1.2)) that tells us how sticky the graph's center is. For more on the Walsh's process see [3, 26, 30, 35].

FIGURE 3. State-space collapse. As permeability coefficients c_i become infinite, times spent at the points $(i, 0)$, $i \in \mathcal{K}$ before jumps become shorter and shorter. As a result, in the limit all these points are lumped together and S_k becomes $K_{1,k}$ (here $k = 5$).

1.3. The main result

Let p be a fixed set of parameters for A_p^{s-o} , and for $\varepsilon > 0$ let $p(\varepsilon)$ be the same set with c_i s replaced by $\varepsilon^{-1}c_i$, $i \in \mathcal{K}$. Our first limit theorem (Theorem 3.2) says that the semigroups generated by $A_{p(\varepsilon)}^{s-o}$ converge, as $\varepsilon \rightarrow 0$, to the semigroup of sticky Walsh's process with parameters

$$\alpha_i := db_i c_i^{-1}, i \in \mathcal{K} \quad \text{and} \quad \beta := d \sum_{j \in \mathcal{K}} a_j c_j^{-1} \quad (1.2)$$

where $d := \frac{1}{\sum_{j \in \mathcal{K}} (a_j + b_j) c_j^{-1}}$ is a normalizing constant; this set of parameters will be denoted $q(p)$. In the case of $k = 2$ and $a_1 = a_2 = 0$ the result described above has been proved in [8], and later reproduced in [9]; see also [14] for a recent continuation.

To explain the meaning of the theorem we note first that the state-space of the snapping-out Brownian motion can also be thought of as the $K_{1,k}$ graph, provided that we imagine that at the graph's center there is a multi-faceted, semipermeable membrane, and thus we distinguish between positions 'virtually at the graph's center' but on the i th edge, $i \in \mathcal{K}$ (we are thus doing a reverse process to that of lumping points). In this interpretation, c_i is the permeability coefficient, telling us how quickly a particle diffusing on the i th edge can filter through the membrane to continue its chaotic motion on the other side. By replacing c_i by $\varepsilon^{-1}c_i$ for all $i \in \mathcal{K}$ and letting $\varepsilon \rightarrow 0$ we make the membrane completely permeable, and thus the limit process's state-space reduces to $K_{1,k}$ (see Figure 3). Formulae (1.2) show that despite the apparent absence of the membrane, in the limit there remains some kind of asymmetry in the way particles approaching the graph's center from different edges pass through this center. Thus, Walsh's sticky process can be seen as a process with a trace of semipermeable membrane at the graph's center.

On the more technical side, Theorem 3.2 says that the semigroups $\{e^{tA_{p(\varepsilon)}^{s-o}}, t \geq 0\}$, which are defined on $C(S_k)$, converge only on $C(K_{1,k}) \subset C(S_k)$. In Sections 4 and 5, devoted to the case of $a_i = 0$, $i \in \mathcal{K}$, we complement this theorem with information on convergence outside of $C(K_{1,k})$, and on convergence of the related cosine families — see Theorems 4.1 and 5.1,

and Corollary 5.2. An estimate of the growth of stochastic matrices involved constitutes a key element in this analysis.

The main results are preceded with Section 2 where, as a preparation, we prove two generation theorems, and Section 3.1, where they are put into the perspective of the general theory of convergence of semigroups and cosine families.

2. Two generation theorems

In this section we show that operators defined in Introduction are indeed Feller generators; in particular, we compute their resolvents which will constitute a key to our main limit theorem. We start with a linear algebra lemma.

Lemma 2.1. *Let $A_i, B_i, C_i, i \in \mathcal{K}$ be given constants such that $A_i > 0$. Then, for any $\varepsilon > 0$ there is precisely one solution $(D_i(\varepsilon))_{i \in \mathcal{K}} \in \mathbb{R}^k$ to the system*

$$\varepsilon A_i D_i(\varepsilon) = \varepsilon B_i + \frac{1}{k-1} \sum_{j \neq i} (C_j + D_j(\varepsilon)) - C_i - D_i(\varepsilon), \quad i \in \mathcal{K}. \quad (2.1)$$

Moreover, the limits $\lim_{\varepsilon \rightarrow 0} D_i(\varepsilon), i \in \mathcal{K}$ exist and are finite.

Proof. The idea is to rewrite (2.1) so that uniqueness and convergence of $D_i(\varepsilon)$ becomes evident. To this end, we let

$$D(\varepsilon) = \sum_{i \in \mathcal{K}} A_i D_i(\varepsilon) \quad (2.2)$$

and note that, by (2.1), $D(\varepsilon) = \sum_{i \in \mathcal{K}} B_i$. It follows that $D(\varepsilon)$ in fact does not depend on ε and we will write simply D instead.

Without loss of generality, we assume from now on that $A_k = \max_{i \in \mathcal{K}} A_i$. Then, by substituting $\frac{D}{A_k} - \sum_{i \neq k} \frac{A_i}{A_k} D_i(\varepsilon)$ for $D_k(\varepsilon)$ into (2.1), we obtain the following system of relations

$$\begin{aligned} \left(1 + \varepsilon A_i + \frac{A_i}{(k-1)A_k}\right) D_i(\varepsilon) &= \varepsilon B_i + \frac{1}{k-1} \sum_{j \neq i} C_j - C_i + \frac{D}{(k-1)A_k} \\ &+ \frac{1}{k-1} \sum_{j \neq i, k} \left(1 - \frac{A_j}{A_k}\right) D_j(\varepsilon), \end{aligned} \quad (2.3)$$

involving variables with the first $k-1$ indexes

$$i \in \mathcal{L} := \{1, \dots, k-1\}.$$

This system is easier to handle. To see this, we equip \mathbb{R}^{k-1} with the norm $\|(\xi_i)_{i \in \mathcal{L}}\| := \max_{i \in \mathcal{L}} |\xi_i|$. Then, for any $\varepsilon \geq 0$, the norm of the linear operator $O_\varepsilon : \mathbb{R}^{k-1} \rightarrow \mathbb{R}^{k-1}$ given by

$$O_\varepsilon(\xi_i)_{i \in \mathcal{L}} = \left(\frac{1}{k-1} \frac{1}{m_i(\varepsilon)} \sum_{j \in \mathcal{L} \setminus \{i\}} \left(1 - \frac{A_j}{A_k}\right) \xi_j \right)_{i \in \mathcal{L}}$$

where $m_i(\varepsilon) := 1 + \varepsilon A_i + \frac{A_i}{(k-1)A_k} > 1$, is smaller than 1. For, $\|O_\varepsilon\|$ does not exceed

$$\max_{i \in \mathcal{L}} \frac{1}{k-1} \frac{1}{m_i(\varepsilon)} \sum_{j \in \mathcal{L} \setminus \{i\}} \left(1 - \frac{A_j}{A_k}\right) < \max_{i \in \mathcal{L}} \frac{1}{k-1} \sum_{j \in \mathcal{L} \setminus \{i\}} \left(1 - \frac{A_j}{A_k}\right) < \frac{k-2}{k-1} < 1.$$

Hence, $I - O_\varepsilon$ is invertible and so (2.1) has the unique solution

$$(D_i(\varepsilon))_{i \in \mathcal{L}} = (I - O_\varepsilon)^{-1} (E_i(\varepsilon))_{i \in \mathcal{L}} \quad (2.4)$$

where $E_i(\varepsilon) = \varepsilon B_i + \frac{1}{k-1} \sum_{j \neq i} C_j - C_i + \frac{D}{(k-1)A_k}$, $i \in \mathcal{L}$. Moreover, we have $\lim_{\varepsilon \rightarrow 0} O_\varepsilon = O_0$ and $\lim_{\varepsilon \rightarrow 0} E_i(\varepsilon) = -C_i + \frac{1}{k-1} \sum_{j \neq i} C_j + \frac{1}{k-1} \frac{D}{A_k}$, $i \in \mathcal{K}$. Hence, (2.4) establishes convergence of $(D_i(\varepsilon))_{i \in \mathcal{L}}$, as $\varepsilon \rightarrow 0$. Since the sum in (2.2) does not depend on ε and A_i s are nonzero, this implies convergence of all $D_i(\varepsilon)$ s and thus completes the proof. \square

Proposition 2.2. *For any set p of non-negative parameters a_i, b_i, c_i with $b_i > 0$, the operator A_p^{s-o} of Section 1.1 is a Feller generator.*

Proof. A_p^{s-o} is obviously densely defined, and arguing as, for example, in [10, Sec. 6] we find out that this operator satisfies the positive-maximum principle. Hence, by [25, Thm 19.11] or [6, Thm. 8.3.4], we are to check only that for any $g \in C(S_k)$ and $\lambda > 0$ there is an $f \in D(A_p^{s-o})$ solving $\lambda f - A_p^{s-o} f = g$, that is, for any $(g_i)_{i \in \mathcal{K}} \in \mathfrak{F}_k$ and $\lambda > 0$ there is an $(f_i)_{i \in \mathcal{K}} \in D(A_p^{s-o})$ such that $\lambda f_i - f_i'' = g_i$, $i \in \mathcal{K}$. (Such an $(f_i)_{i \in \mathcal{K}}$ is unique, because A_p^{s-o} satisfies the positive-maximum principle and is thus dissipative — see [20, Lemma 2.1, p. 165].)

To this end, we search for f_i s of the form

$$f_i(x) := C_i e^{\sqrt{\lambda}x} + D_i e^{-\sqrt{\lambda}x} - \frac{1}{\sqrt{\lambda}} \int_0^x \sinh \sqrt{\lambda}(x-y) g_i(y) dy, \quad x \geq 0, i \in \mathcal{K}, \quad (2.5)$$

for some constants $C_i, D_i, i \in \mathcal{K}$, and note that the limits $\lim_{x \rightarrow \infty} f_i(x)$ exist and are finite iff

$$C_i = \frac{1}{2\sqrt{\lambda}} \int_0^\infty e^{-\sqrt{\lambda}y} g_i(y) dy, \quad i \in \mathcal{K}. \quad (2.6)$$

Moreover, condition (1.1) is satisfied iff

$$\gamma_i^+ D_i = \gamma_i^- C_i + a_i c_i^{-1} g_i(0) + \frac{1}{k-1} \sum_{j \neq i} (C_j + D_j) - C_i - D_i, \quad i \in \mathcal{K} \quad (2.7)$$

where $\gamma_i^\pm := b_i c_i^{-1} \sqrt{\lambda} \pm \lambda a_i c_i^{-1}$, $i \in \mathcal{K}$. Since (2.7) is obviously a particular case of (2.1) with $\varepsilon = 1$, $A_i = \gamma_i^+$ and $B_i = \gamma_i^- C_i + a_i c_i^{-1} g_i(0)$, existence of (unique) solution to this system is guaranteed by Lemma 2.1. \square

Our second generation theorem is a simple case of the general result of [26, Thm. 2.8] and [27, Thm. 3.7], but we sketch its proof here since in what follows we need the form of the resolvent of A_q^{SP} .

Proposition 2.3. *Operator A_q^{SP} is a Feller generator.*

Proof. We proceed as in the proof of the previous proposition. First of all, density of $D(A_q^{\text{sp}})$ and the positive-maximum principle for A_q^{sp} do not pose a problem. Secondly, to find a solution to the resolvent equation we search for f_i s of the form (2.5) (with C_i s defined by (2.6)), and note that the defining conditions (b) and (c) are satisfied iff

$$f_i(0) = f_j(0) \quad \text{that is} \quad C_i + D_i = C_j + D_j, \quad i, j \in \mathcal{K} \quad (2.8)$$

and

$$\beta[\lambda(C_i + D_i) - g(0)] = \sqrt{\lambda} \sum_{j \in \mathcal{K}} \alpha_j (C_j - D_j), \quad i \in \mathcal{K}, \quad (2.9)$$

respectively. Denoting by $f(0)$ the common value of (2.8) we check that the system (2.8)–(2.9) has the following unique solution: $D_i = f(0) - C_i, i \in \mathcal{K}$ where $f(0) = \frac{\beta g(0) + 2\sqrt{\lambda} \sum_{i \in \mathcal{K}} \alpha_i C_i}{\lambda\beta + \sqrt{\lambda}(1-\beta)}$. This completes the proof. \square

3. The main convergence theorem

3.1. A sketch of the theory of convergence of semigroups and bird's-eye view of our results

The main idea of the Trotter–Kato–Neveu convergence theorem [1, 19, 22, 32], a cornerstone of the theory of convergence of semigroups [9, 16], is that convergence of resolvents of *equibounded* semigroups in a Banach space F , gives an insight into convergence of the semigroups themselves. Hence, in studying the limit of equibounded semigroups, say, $\{e^{tB_\varepsilon}, t \geq 0\}$, generated by the operators $B_\varepsilon, \varepsilon > 0$ we should first establish existence of the strong limit

$$R_\lambda := \lim_{\varepsilon \rightarrow 0} (\lambda - B_\varepsilon)^{-1}.$$

The general theory of convergence (see [9, Chapter 8]) covers also the case in which, unlike in the classical version of the Trotter–Kato–Neveu theorem, the (common) range of the operators $R_\lambda, \lambda > 0$ so-obtained is *not* dense in F , and stresses the role of the so-called *regularity space*, defined as the closure of the range of R_λ :

$$F_{\text{reg}} := \text{cl}(\text{Range} R_\lambda) \subset F.$$

Namely, F_{reg} turns out to coincide with the set of $f \in F$ such the limit $T(t)f := \lim_{\varepsilon \rightarrow 0} e^{tB_\varepsilon} f$ exists and is uniform with respect to t in compact subintervals of $[0, \infty)$; then $\{T(t), t \geq 0\}$, termed the *regular limit* of $\{e^{tB_\varepsilon}, t \geq 0\}, \varepsilon > 0$, is a strongly continuous semigroup in F_{reg} .

It should be stressed, though, that this statement does not exclude the possibility of the existence of $f \notin F_{\text{reg}}$ such that the strong limit $\lim_{\varepsilon \rightarrow 0} e^{tB_\varepsilon} f$ exists for all $t \geq 0$. Such *irregular* convergence of semigroups, which is known to be always uniform with respect to t in compact subsets of $(0, \infty)$ — see [5] or [9, Thm 28.4] — is not so uncommon, especially in the context of singular perturbations [2, 9, 31], but needs to be established by different means.

In our first limit theorem (Theorem 3.2) we fix the set p of parameters a_i, b_i, c_i of Section 1.1 and consider operators $A_{p(\varepsilon)}^{\text{s-o}}, \varepsilon > 0$ defined as $A_p^{\text{s-o}}$ with

$p = p(\varepsilon)$ obtained from p by replacing all c_i s by $\varepsilon^{-1}c_i$ and leaving the remaining parameters intact. We prove that the regularity space for this family of semigroups of operators is $C(K_{1,k}) \subset C(S_k)$, and that the sticky Walsh's process is their regular limit. In Section 4, under additional assumption that all a_i are zero, we will show $A_{p(\varepsilon)}^{s-o}$ generate also equibounded cosine families, and therefore the limit $\lim_{\varepsilon \rightarrow 0} e^{tA_{p(\varepsilon)}^{s-o}} f, t \geq 0$ exists also for $f \in C(S_k) \setminus C(K_{1,k})$. In Section 5 we show that convergence of semigroups (and cosine families) on the regularity space is in fact uniform with respect to t , and that outside of this subspace the cosine families do not converge at all.

3.2. The main theorem

Let p and $p(\varepsilon), \varepsilon > 0$ be as in the preceding section. In other words, elements of the domain of $A_{p(\varepsilon)}^{s-o}$ satisfy the transmission conditions

$$\varepsilon a_i f_i''(0) - \varepsilon b_i f_i'(0) = c_i \left[\frac{1}{k-1} \sum_{j \neq i} f_j(0) - f_i(0) \right], \quad i \in \mathcal{K}, \quad (3.1)$$

and we are interested in the strong limit of the semigroups $\{e^{tA_{p(\varepsilon)}^{s-o}}, t \geq 0\}$ generated by $A_{p(\varepsilon)}^{s-o}$, as $\varepsilon \rightarrow 0$. As explained above, our first task is to prove existence of the limit of resolvents of $A_{p(\varepsilon)}^{s-o}$. This is achieved in the following proposition.

Proposition 3.1. *The limit $R_{\lambda g} := \lim_{\varepsilon \rightarrow 0} (\lambda - A_{p(\varepsilon)}^{s-o})^{-1} g$ exists for all $g \in C(S_k)$ and $\lambda > 0$, and the regularity space for $\{e^{tA_{p(\varepsilon)}^{s-o}}, t \geq 0\}, \varepsilon > 0$ coincides with $C(K_{1,k})$. Moreover, for $g \in C(K_{1,k})$, $R_{\lambda g} = (\lambda - A_{q(p)}^{sp})^{-1} g$ where $q(p)$ is the set of parameters given in (1.2).*

Proof. Fix $g \in C(S_k)$. Function $f_\varepsilon = (\lambda - A_{p(\varepsilon)}^{s-o})^{-1} g$ solves the resolvent equation for $A_{p(\varepsilon)}^{s-o}$ and hence, as we know from the proof of Proposition 2.2, is of the form (2.5)–(2.6) with certain $D_i = D_i(\varepsilon)$. More specifically, the vector of these coefficients is a unique solution to the system

$$\varepsilon \gamma_i^+ D_i(\varepsilon) = \varepsilon \gamma_i^- C_i + \varepsilon a_i c_i^{-1} g_i(0) + \frac{1}{k-1} \sum_{j \neq i} (C_j + D_j(\varepsilon)) - C_i - D_i(\varepsilon), \quad (3.2)$$

where, as in Proposition 2.2, $\gamma_i^\pm := b_i c_i^{-1} \sqrt{\lambda} \pm \lambda a_i c_i^{-1}, i \in \mathcal{K}$. We are thus dealing again with a special case of (2.1), and Lemma 2.1 tells us that the limits $D_i^0 := \lim_{\varepsilon \rightarrow 0} D_i(\varepsilon), i \in \mathcal{K}$ exist and are finite. Since neither the first nor the third term in (2.5) depend on ε , this establishes existence of the limit $\lim_{\varepsilon \rightarrow 0} (\lambda - A_{p(\varepsilon)}^{s-o})^{-1} g$.

To prove the second sentence in the proposition, we first let $\varepsilon \rightarrow 0$ in (3.2) to obtain

$$C_i + D_i^0 = \frac{1}{k-1} \sum_{j \neq i} (C_j + D_j^0), \quad i \in \mathcal{K}. \quad (3.3)$$

This shows that $f_i(0) = C_i + D_i^0$ does not depend on $i \in \mathcal{K}$, that is, that $R_{\lambda g}$ belongs to $C(K_{1,k})$. Next, we sum both sides of (3.2) over $i \in \mathcal{K}$ and divide

by ε . This renders

$$\sum_{i \in \mathcal{K}} (b_i c_i^{-1} \sqrt{\lambda} + \lambda a_i c_i^{-1}) D_i^0 = \sum_{i \in \mathcal{K}} (b_i c_i^{-1} \sqrt{\lambda} - \lambda a_i c_i^{-1}) C_i + \sum_{i \in \mathcal{K}} a_i c_i^{-1} g_i(0).$$

If $g \in C(K_{1,k})$, that is, if $g_i(0)$ does not depend on i , this relation can be rearranged as

$$\sum_{i \in \mathcal{K}} (a_i c_i^{-1}) (\lambda (C_i + D_i^0) - g(0)) = \sqrt{\lambda} \sum_{j \in \mathcal{K}} b_j c_j^{-1} (C_j - D_j^0).$$

This means, however, that condition (2.9) is satisfied with α_i s and β specified in (1.2), because we know that $C_i + D_i^0$ does not depend on i . It follows that for the stated choice of parameters, D_i s of (2.8)–(2.9), coincide with D_i^0 s. This establishes $R_\lambda g = (\lambda - A_{q(p)}^{\text{SP}})^{-1} g$ for $g \in C(K_{1,k})$.

As a by-product, the range of R_λ contains $D(A_{q(p)}^{\text{SP}})$, and since the latter is dense in $C(K_{1,k})$ the closure of the range of R_λ contains $C(K_{1,k})$. But we have already established that this range is contained in $C(K_{1,k})$. Hence, the closure of the range of R_λ coincides with $C(K_{1,k})$, as claimed. \square

Proposition 3.1 says in fact more than it is visible on its surface. To wit, the fact that on the regularity space $C(K_{1,k})$, R_λ coincides with $(\lambda - A_{q(p)}^{\text{SP}})^{-1}$ implies that $A_{q(p)}^{\text{SP}}$ is the generator of the regular limit of $\{e^{tA_p^{\text{S-O}}}, t \geq 0\}$ — see e.g. [9, Thm. 8.1 and Corollary 8.3], compare [6, Sections 8.4.3 and 8.4.4]. As an immediate corollary we obtain thus the following main theorem of this section.

Theorem 3.2. *We have*

$$\lim_{\varepsilon \rightarrow 0} e^{tA_p^{\text{S-O}}(\varepsilon)} f = e^{tA_{q(p)}^{\text{SP}}} f, \quad f \in C(K_{1,k})$$

with the limit uniform with respect to t in compact subsets of $[0, \infty)$.

In view of the Trotter–Sova–Kurtz–Mackevičius theorem [25], this result can be seen as expressing a convergence of the random processes involved. We note that A. Gregosiewicz in [23] has found a different proof of our theorem based on a decomposition of resolvents involved.

4. Convergence outside of $C(K_{1,k})$

4.1. Introductory remarks

As already mentioned in Section 3.1, Theorem 3.2 need not tell the entire story: it may happen that $\lim_{\varepsilon \rightarrow 0} e^{tA_p^{\text{S-O}}(\varepsilon)} f$ exists also for $f \in C(S_k) \setminus C(K_{1,k})$, except that this limit cannot be uniform in compact subintervals containing 0. Such convergence of semigroups outside of regularity space can be deduced from the convergence of their resolvents provided that the semigroups enjoy additional regularity properties, such as being uniformly holomorphic — see e.g. [9, Chapter 31]. In [15] it has been proved that, in the case of $k = 2$ and $a_1 = a_2 = 0$, each $A_p^{\text{S-O}}$ is a cosine operator family generator, and all these

families are formed by operators of norm not exceeding 5. As a corollary, in [14] we show that in this case convergence spoken of in Theorem 3.2 extends beyond $f \in C(K_{1,k})$.

It is the purpose of this section to prove a similar result for general $k \geq 3$. Hence, in what follows we assume that $a_i = 0$, $i \in \mathcal{K}$ and, without loss of generality, take $b_i = 1$, $i \in \mathcal{K}$, so that the entire generator A_p^{s-o} is characterized by the vector $c = (c_1, \dots, c_k) \in \mathbb{R}^k$ of (positive) permeability coefficients; to stress this in what follows we write A_c^{s-o} instead of A_p^{s-o} . As a result, transmission conditions (1.1) take the form

$$f'_i(0) = c_i \left[f_i(0) - \frac{1}{k-1} \sum_{j \neq i} f_j(0) \right], \quad i \in \mathcal{K}. \quad (4.1)$$

We will show (see Theorem 4.1) that each A_c^{s-o} generates a strongly continuous cosine family $\{\text{Cos}_{A_c^{s-o}}(t), t \in \mathbb{R}\}$ such that

$$\|\text{Cos}_{A_c^{s-o}}(t)\| \leq M = M(c), \quad t \in \mathbb{R},$$

where $M(c)$ has the following property: for any $r > 0$, $M(rc) = M(c)$. In particular, even though we cannot claim that (as in the case of $k = 2$) there is a universal bound for all cosine families generated by A_c^{s-o} s, we know that for fixed c the operators $A_{c(\varepsilon)}^{s-o}$, defined as A_c^{s-o} with c replaced by $\varepsilon^{-1}c$, generate cosine families that are bounded by a universal constant:

$$\|\text{Cos}_{A_{c(\varepsilon)}^{s-o}}(t)\| \leq M(c), \quad t \in \mathbb{R}, \varepsilon > 0. \quad (4.2)$$

Theorem 3.2 says that the semigroups generated by operators $A_{c(\varepsilon)}^{s-o}$ converge, as $\varepsilon \rightarrow 0$, to the semigroup describing the Walsh's process with parameters

$$\alpha_i := \frac{1}{c_i \sum_{j \in \mathcal{K}} c_j^{-1}}, \quad i \in \mathcal{K} \quad \text{and} \quad \beta := 0. \quad (4.3)$$

To denote this simpler set of parameters we write $\alpha(c)$ instead of $q(p)$.

As explained in detail in [14], estimate (4.2), when combined with Proposition 3.1, implies the following second main result of our paper.

Theorem 4.1.

- (a) For $f \in C(K_{1,k})$, $\lim_{\varepsilon \rightarrow 0} \text{Cos}_{A_{c(\varepsilon)}^{s-o}}(t)f = \text{Cos}_{A_{\alpha(c)}^{\text{sp}}}(t)f$ uniformly in $t \in [0, t_0]$ for $t_0 > 0$.
- (b) For $f \in C(S_k) \setminus C(K_{1,k})$, $\lim_{\varepsilon \rightarrow 0} e^{tA_{c(\varepsilon)}^{s-o}}f = e^{tA_{\alpha(c)}^{\text{sp}}}f$ uniformly in $t \in (t_0^{-1}, t_0)$ for $t_0 > 1$.

To elaborate on these succinct statements: first of all, $A_{\alpha(c)}^{\text{sp}}$ is also the generator of a cosine family in $C(K_{1,k})$ (see our Section 5 for more details). As such, despite not being densely defined in $C(S_k)$, it is also the generator of a semigroup $\{e^{tA_{\alpha(c)}^{\text{sp}}}, t \geq 0\}$ of operators in $C(S_k)$ — see e.g. [4, Corollary 5.1]. These operators are extensions of those defined in $C(K_{1,k})$, and the semigroup generated by $A_{\alpha(c)}^{\text{sp}}$ is not strongly continuous in $t \in [0, \infty)$ but merely in $t \in (0, \infty)$ (of course, for $f \in C(K_{1,k})$, $\lim_{t \rightarrow 0+} e^{tA_{\alpha(c)}^{\text{sp}}}f = f$). This clarifies statement (b).

Condition (a) also requires a comment. Since we were able to extend convergence of semigroups from $C(K_{1,k})$ to the entire $C(S_k)$, it may seem natural to ask whether the same can be done with convergence of the related cosine families. However, as proved in [12] (see also [9, Chapter 61]), cosine families by nature cannot converge outside of the regularity space. As applied to our case, this theorem tells us that (a) is the best result possible in the sense that the limit cosine family cannot be extended beyond $C(K_{1,k})$ — see also our Section 5.

Finally, we remark that the fact that each A_c^{s-o} is the generator of a cosine family can also be proved using decomposition of resolvent techniques (see [23]); however, this approach does not give a universal bound for the norm of $\text{Cos}_{A_c^{s-o}}(t)$, $t \in \mathbb{R}$, $\varepsilon > 0$ (found in (4.2)).

4.2. Definition of $M(c)$

Given $c = (c_1, \dots, c_k)$ with all $c_i > 0$ we think of the $k \times k$ intensity matrix $Q = (q_{i,j})_{i,j \in \mathcal{K}}$ given by

$$q_{i,j} = \begin{cases} -c_i, & i = j, \\ \frac{c_i}{k-1}, & i \neq j. \end{cases} \quad (4.4)$$

The Markov chain generated by Q is irreducible and its invariant measure is $\alpha = (\alpha_i)_{i \in \mathcal{K}}$, where α_i are defined in (4.3).

Let $c := \max_{i \in \mathcal{K}} c_i$ and $Q_0 := c^{-1}Q$. We denote the entries of the matrix e^{tQ_0} by $p_{i,j}^0(t)$. Since $Q_0 + I_k$, where I_k is the $k \times k$ identity matrix, is a transition matrix of an irreducible and reversible discrete time Markov chain with the invariant measure α , Corollary 2.1.5 in [33] implies that

$$|p_{i,j}^0(t) - \alpha_j| \leq e^{-\omega t} \sqrt{\frac{\alpha_j}{\alpha_i}} = e^{-\omega t} \sqrt{\frac{c_i}{c_j}}, \quad t \geq 0, \quad i, j \in \mathcal{K}, \quad (4.5)$$

where the *spectral gap* ω is the smallest non-zero eigenvalue of $-Q_0$. We note that Q_0 does not change if c is replaced by rc where $r > 0$, and thus neither does change the ω . It follows that the same applies to the constant

$$M = M(c) := \left(1 + 2 \max_{i \in \mathcal{K}} \frac{c_i}{c\omega} \sum_{j \in \mathcal{K}} \left(\sqrt{\frac{c_i}{c_j}} + \frac{1}{k-1} \sum_{\ell \neq i} \sqrt{\frac{c_\ell}{c_j}} \right)\right). \quad (4.6)$$

4.3. Cosine families

A strongly continuous family $\{C(t), t \in \mathbb{R}\}$ of operators in a Banach space F is said to be a cosine family iff $C(0)$ is the identity operator and

$$2C(t)C(s) = C(s+t) + C(t-s), \quad t, s \in \mathbb{R}.$$

The generator of such a family is defined by

$$Af = \lim_{t \rightarrow 0} 2t^{-2}(C(t)f - f)$$

for all $f \in F$ such the limit on the right-hand side exists. For example, in $C[-\infty, \infty]$, the space of continuous functions on \mathbb{R} that have finite limits at $\pm\infty$, there is the *basic cosine family* given by

$$C(t)f(x) = \frac{1}{2}[f(x+t) + f(x-t)], \quad x \in \mathbb{R}, t \in \mathbb{R}.$$

Its generator is the one-dimensional Laplace operator $f \mapsto f''$ with domain composed of twice continuously differentiable functions on \mathbb{R} such that $f'' \in C[-\infty, \infty]$.

Each cosine family generator is automatically the generator of a strongly continuous semigroup (but not vice versa). The semigroup such operator generates is given by the *Weierstrass formula* (see e.g. [1, p. 219])

$$T(0)f = f \quad \text{and} \quad T(t)f = \frac{1}{2\sqrt{\pi t}} \int_{-\infty}^{\infty} e^{-\frac{s^2}{4t}} C(s) f ds, \quad t > 0, f \in F.$$

This formula expresses the fact that the cosine family is thus (in this case) a more fundamental object than the semigroup, and properties of the semigroup can be hidden in those of the cosine family (see e.g. [11]). Moreover, semigroups that are generated by generators of cosine families are much more regular than other semigroups. In particular, such semigroups are holomorphic, but even among holomorphic semigroups there are those that are not generated by cosine family generators (see [1] again).

4.4. Lord Kelvin's method of images and the generation theorem

For a number of Laplace operators in $C[0, \infty]$ with domains characterized by Feller–Wentzel boundary conditions at $x = 0$ the cosine families they generate can be constructed semi-explicitly as (isomorphic images of) subspace cosine families for the basic cosine families in $C[-\infty, \infty]$ — see [7, 15] and references given there. The trick, known as the *Lord Kelvin method of images* [7, 21], comes down to noticing that each boundary condition unequivocally shapes extensions of elements of $C[0, \infty]$ to elements of $C[-\infty, \infty]$; for example, the Neumann and Dirichlet boundary conditions lead to even and odd extensions, respectively. These extensions form an invariant subspace for the basic cosine family, and the cosine family we are searching for turns out to be an isomorphic image of the basic cosine family as restricted to this subspace.

In this section we use the same idea to show that the operator $A_c^{\varepsilon-o}$ with transmission conditions (4.1) generates a cosine family $\{\text{Cos}_{A_c^{\varepsilon-o}}(t), t \in \mathbb{R}\}$ of operators in \mathfrak{F}_k : we will construct $\{\text{Cos}_{A_c^{\varepsilon-o}}(t), t \in \mathbb{R}\}$ as an isomorphic image of a subspace cosine family of the *Cartesian product cosine family* $\{C_D(t), t \in \mathbb{R}\}$ ('D' for 'Descartes'). The latter is defined in the Cartesian product space

$$\mathfrak{G}_k := (C[-\infty, \infty])^k,$$

(equipped with the maximum norm) by the formula

$$C_D(t)(f_i)_{i \in \mathcal{K}} = (C(t)f_i)_{i \in \mathcal{K}}, \quad (f_i)_{i \in \mathcal{K}} \in \mathfrak{G}_k, t \in \mathbb{R}.$$

This is to say that $\text{Cos}_{A_c^{\varepsilon-o}}(t)$ will be found to be of the form

$$\text{Cos}_{A_c^{\varepsilon-o}}(t)(f_i)_{i \in \mathcal{K}} = RC_D(t)(\tilde{f}_i)_{i \in \mathcal{K}}, \quad (f_i)_{i \in \mathcal{K}} \in \mathfrak{F}_k, t \in \mathbb{R}, \quad (4.7)$$

where $\tilde{f}_i \in C[-\infty, \infty]$, $i \in \mathcal{K}$, is a suitable extension of $f_i \in C[0, \infty]$ and $R: \mathfrak{G}_k \rightarrow \mathfrak{F}_k$ is the restriction operator assigning to a $(g_i)_{i \in \mathcal{K}} \in \mathfrak{G}_k$ the member $(f_i)_{i \in \mathcal{K}}$ of \mathfrak{F}_k given by $f_i = g_i|_{\mathbb{R}_+}$, $i \in \mathcal{K}$. Our first lemma says that

extensions $\tilde{f}_i, i \in \mathcal{K}$ are determined uniquely by the fact that a cosine family leaves the domain of its generator invariant.

Lemma 4.2. *For $(f_i)_{i \in \mathcal{K}} \in D(A_c^{s-o})$ there exists its unique extension $(\tilde{f}_i)_{i \in \mathcal{K}} \in \mathfrak{G}_k$ such that*

$$RC_D(t)(\tilde{f}_i)_{i \in \mathcal{K}} \in D(A_c^{s-o})$$

for $t \in \mathbb{R}$. Moreover, each $\tilde{f}_i, i \in \mathcal{K}$ belongs to the domain of the generator of the basic cosine family and

$$\|(\tilde{f}_i)_{i \in \mathcal{K}}\|_{\mathfrak{G}_k} \leq M \|(f_i)_{i \in \mathcal{K}}\|_{\mathfrak{F}_k}, \quad (4.8)$$

where M is defined in (4.6).

Proof. **Step I, existence and uniqueness of $\tilde{f}_i, i \in \mathcal{K}$.** Our task is to find

$$g_i(x) := \tilde{f}_i(-x), \quad x \geq 0, i \in \mathcal{K}, \quad (4.9)$$

satisfying compatibility conditions $f_i(0) = g_i(0)$. Since $C_D(t) = C_D(-t), t \geq 0$, we must also have

$$\frac{d}{dx} [\tilde{f}_i(x-t) + \tilde{f}_i(x+t)]|_{x=0} = c_i \left[\tilde{f}_i(t) + \tilde{f}_i(-t) - \frac{1}{k-1} \sum_{j \neq i} (\tilde{f}_j(t) + \tilde{f}_j(-t)) \right],$$

that is

$$f'_i(t) - g'_i(t) = c_i \left[f_i(t) + g_i(t) - \frac{1}{k-1} \sum_{j \neq i} (f_j(t) + g_j(t)) \right], \quad (4.10)$$

for $t \geq 0, i \in \mathcal{K}$. This system can be rewritten as

$$(g_i - f_i)'_{i \in \mathcal{K}} = Q(g_i - f_i)_{i \in \mathcal{K}} + 2Q(f_i)_{i \in \mathcal{K}},$$

where $Q = (q_{i,j})_{i,j \in \mathcal{K}}$ is the intensity matrix defined in (4.4). Hence, g_i are uniquely determined and (because of the compatibility condition) given by

$$(g_i(t))_{i \in \mathcal{K}} = (f_i(t))_{i \in \mathcal{K}} + 2 \int_0^t [e^{(t-s)Q} Q] (f_i(s))_{i \in \mathcal{K}} ds, \quad t \geq 0. \quad (4.11)$$

From now on, we treat (4.10) and (4.11) as the definition of $(\tilde{f}_i)_{i \in \mathcal{K}}$.

Step II, an estimate for $p'_{i,j}(t)$. We note that $e^{tQ}, t \geq 0$ is the matrix of transition probabilities, say, $p_{i,j}(t)$, for the Markov chain with intensity matrix Q , whereas $Qe^{tQ} = e^{tQ}Q = \frac{d}{dt} e^{tQ} = (p'_{i,j}(t))_{i,j \in \mathcal{K}}$. Moreover,

$$\begin{aligned} |p'_{i,j}(t)| &= \left| \sum_{\ell \in \mathcal{K}} q_{i,\ell} p_{\ell,j}(t) \right| = \left| \sum_{\ell \neq i} \frac{c_i}{k-1} p_{\ell,j}(t) - c_i p_{i,j}(t) \right| \\ &\leq \frac{c_i}{k-1} \sum_{\ell \neq i} |p_{\ell,j}(t) - p_{i,j}(t)| \leq \frac{c_i}{k-1} \sum_{\ell \neq i} (|p_{\ell,j}(t) - \alpha_j| + |p_{i,j}(t) - \alpha_j|) \end{aligned}$$

for $t \geq 0, i, j \in \mathcal{K}$. Next, (4.5) and $p_{i,j}(t) = p_{i,j}^0(ct), i, j \in \mathcal{K}$ imply that

$$|p_{i,j}(t) - \alpha_j| \leq e^{-c\omega t} \sqrt{\frac{c_i}{c_j}}, \quad t \geq 0, i, j \in \mathcal{K}. \quad (4.12)$$

This in turn renders

$$|p'_{i,j}(t)| = c_i e^{-c\omega t} \left(\sqrt{\frac{c_i}{c_j}} + \frac{1}{k-1} \sum_{\ell \neq i} \sqrt{\frac{c_\ell}{c_j}} \right), \quad t \geq 0, \quad i, j \in \mathcal{K}. \quad (4.13)$$

The last two estimates will be of key importance in what follows.

Step III, each \tilde{f}_i belongs to $C[-\infty, \infty]$, and (4.8) holds. For our first claim in this step it suffices to show that $g_i \in C[0, \infty]$, and since continuity of g_i is clear, it is enough to prove that the integral in (4.11) converges, as $t \rightarrow \infty$, to $\Pi m - m$ where $m := (m_i)_{i \in \mathcal{K}}, m_i := \lim_{t \rightarrow \infty} f_i(t)$ and $\Pi m = (\sum_{j \in \mathcal{K}} \alpha_j m_j)_{i \in \mathcal{K}}$. Now, the last statement is true if $f_i(t) = m_i$ for $t \geq 0$ and $i \in \mathcal{K}$ because then the integral equals $\int_0^t e^{(t-s)Q} Q m \, ds = e^{tQ} m - m$ and (4.12) implies that $\lim_{t \rightarrow \infty} e^{tQ} m = \Pi m$. Hence, we are left with showing that the integral in question converges to 0 provided that $m = 0$.

To this end, we let \mathbb{R}^k be equipped with the maximum norm. Then, (4.13) shows that the norm of $e^{tQ} Q$ as the operator in \mathbb{R}^k can be estimated as follows:

$$\|e^{tQ} Q\| = \max_{i \in \mathcal{K}} \sum_{j \in \mathcal{K}} |p'_{i,j}(t)| \leq c M_0 e^{-c\omega t} \quad t \geq 0 \quad (4.14)$$

where $M_0 := \max_{i \in \mathcal{K}} \sum_{j \in \mathcal{K}} \left(\sqrt{\frac{c_i}{c_j}} + \frac{1}{k-1} \sum_{\ell \neq i} \sqrt{\frac{c_\ell}{c_j}} \right)$.

Next, if $m = 0$, given $\epsilon > 0$ we can find a $t_0 > 0$ such that $|f_i(s)| < \epsilon, i \in \mathcal{K}$ as long as $s \geq t_0$. Hence, for $t > t_0$ the integral in question does not exceed $\int_0^{t_0} \|e^{(t-s)Q} Q\| \|f\|_{\mathfrak{F}_k} \, ds + \epsilon \int_{t_0}^t \|e^{(t-s)Q} Q\| \, ds$. Since, by (4.14) the first summand converges to 0, as $t \rightarrow \infty$, and the second is bounded by $\frac{\epsilon M_0}{c\omega}$, our first claim follows.

As to the other claim, (4.13) implies also $\int_0^\infty |p'_{i,j}(t)| \, dt \leq \frac{c_i}{c\omega} \left(\sqrt{\frac{c_i}{c_j}} + \frac{1}{k-1} \sum_{\ell \neq i} \sqrt{\frac{c_\ell}{c_j}} \right)$. Thus, (4.11) combined with $\int_0^t [e^{(t-s)Q} Q](f_i(s))_{i \in \mathcal{K}} \, ds = \left(\sum_{j \in \mathcal{K}} \int_0^t p'_{i,j}(t-s) f_j(s) \, ds \right)_{i \in \mathcal{K}}$ shows that

$$\|(g_i)_{i \in \mathcal{K}}\| \leq \left(1 + 2 \max_{i \in \mathcal{K}} \sum_{j \in \mathcal{K}} \int_0^\infty |p'_{i,j}(t)| \, dt \right) \leq M \|(f_i)_{i \in \mathcal{K}}\|. \quad (4.15)$$

Hence, (4.8) is established.

Step IV, \tilde{f}_i is in the domain of the generator of the basic cosine family. Since f_i are twice continuously differentiable on $[0, \infty)$, (4.11) shows that so are $g_i, i \in \mathcal{K}$. Also, by differentiating (4.11) we recover (4.10), which in turn, when evaluated at $t = 0$ yields $g'_i(0) = f'_i(0) - 2c_i \left[f_i(0) - \frac{1}{k-1} \sum_{j \neq i} (f_j(0)) \right] = -f'_i(0), i \in \mathcal{K}$. This proves that the left-hand and right-hand derivatives of \tilde{f}_i agree at $t = 0$, and we see from (4.10) that \tilde{f}_i is continuously differentiable on the entire \mathbb{R} . The same relation reveals, furthermore, that g'_i is continuously differentiable on $[0, \infty)$, since so is f'_i , and a little calculation using the already established $f'_i(0) = -g'_i(0)$ yields $f''_i(0) = g''_i(0)$ completing the proof that \tilde{f}_i is twice continuously differentiable.

We are left with proving that the limits $\lim_{t \rightarrow \infty} g_i''(t)$ exist and are finite. To this end, we note first that existence of finite limits $\lim_{t \rightarrow \infty} f_i''(t)$ implies that $\lim_{t \rightarrow \infty} f_i'(t) = 0, i \in \mathcal{K}$. Furthermore, since, as we have established in Step III, $\lim_{t \rightarrow \infty} (g_i(t))_{i \in \mathcal{K}} = m + 2(\Pi m - m)$, and (4.10) can be rewritten as $(g_i'(t))_{i \in \mathcal{K}} = (f_i'(t))_{i \in \mathcal{K}} - Q[(g_i(t))_{i \in \mathcal{K}} + (f_i(t))_{i \in \mathcal{K}}]$, we obtain $\lim_{t \rightarrow \infty} (g_i'(t))_{i \in \mathcal{K}} = -2Q\Pi m = 0$. Hence, differentiating (4.10) once again shows that $\lim_{t \rightarrow \infty} g_i''(t)$ exists and equals $\lim_{t \rightarrow \infty} f_i''(t)$. \square

Lemma 4.2 tells us in particular that if (4.7) is to define a cosine family generated by A_c^{s-o} , there is but one choice for extensions $\tilde{f}_i, i \in \mathcal{K}$. Hence, we introduce the extension operator

$$E: \mathfrak{F}_k \ni (f_i)_{i \in \mathcal{K}} \mapsto (\tilde{f}_i)_{i \in \mathcal{K}} \in \mathfrak{G}_k,$$

where, for all $(f_i)_{i \in \mathcal{K}} \in \mathfrak{F}_k$ (not just for $(f_i)_{i \in \mathcal{K}} \in D(A_c^{s-o})$), $\tilde{f}_i, i \in \mathcal{K}$ are given by (4.9) and (4.11). In terms of E , (4.7) can be written as

$$\text{Cos}_{A_c^{s-o}}(t) = RC_D(t)E, \quad t \in \mathbb{R}, \quad (4.16)$$

and, since, by the lemma, $\|E\| \leq M$, and clearly $\|R\| \leq 1$, we conclude that $\|\text{Cos}_{A_c^{s-o}}(t)\| \leq M, t \in \mathbb{R}$.

Theorem 4.3. *Formula (4.16) defines a strongly continuous cosine family in \mathfrak{F}_k . Moreover, this cosine family is generated by A_c^{s-o} .*

Proof. Let $s \in \mathbb{R}$ and $(f_i)_{i \in \mathcal{K}} \in D(A_c^{s-o})$. By Lemma 4.2, $RC_D(t)E(f_i)_{i \in \mathcal{K}} \in D(A_c^{s-o})$ for all $t \in \mathbb{R}$, and the cosine equation for $\{C_D(t), t \in \mathbb{R}\}$ implies that

$$RC_D(t)C_D(s)E(f_i)_{i \in \mathcal{K}} = \frac{1}{2}RC_D(t+s)E(f_i)_{i \in \mathcal{K}} + \frac{1}{2}RC_D(t-s)E(f_i)_{i \in \mathcal{K}}$$

belongs to $D(A_c^{s-o})$ for $t \in \mathbb{R}$. By uniqueness of extensions for elements of $D(A_c^{s-o})$, established in Lemma 4.2, it follows that $C_D(s)E(f_i)_{i \in \mathcal{K}}$ coincides with $ERC_D(s)E(f_i)_{i \in \mathcal{K}}$. Hence, for all $t \in \mathbb{R}$

$$\begin{aligned} 2 \text{Cos}_{A_c^{s-o}}(t) \text{Cos}_{A_c^{s-o}}(s)(f_i)_{i \in \mathcal{K}} &= 2RC_D(t)[ERC_D(s)E](f_i)_{i \in \mathcal{K}} \\ &= 2RC_D(t)C_D(s)E(f_i)_{i \in \mathcal{K}} \\ &= RC_D(t+s)E(f_i)_{i \in \mathcal{K}} + RC_D(t-s)E(f_i)_{i \in \mathcal{K}} \\ &= \text{Cos}_{A_c^{s-o}}(t+s)(f_i)_{i \in \mathcal{K}} + \text{Cos}_{A_c^{s-o}}(t-s)(f_i)_{i \in \mathcal{K}}. \end{aligned}$$

Since $D(A_c^{s-o})$ is dense in \mathfrak{F}_k , this proves that $\{\text{Cos}_{A_c^{s-o}}(t), t \in \mathbb{R}\}$ is a cosine family. The family is strongly continuous since so is the Cartesian product cosine family $\{C_D(t), t \in \mathbb{R}\}$.

Turning to the claim concerning the generator: Let $(f_i)_{i \in \mathcal{K}} \in D(A_c^{s-o})$. By Lemma 4.2 each \tilde{f}_i belongs to the domain of the basic cosine family and thus we have $\lim_{t \rightarrow 0} \frac{2}{t^2}[C(t)\tilde{f}_i - \tilde{f}_i] = \tilde{f}_i'', i \in \mathcal{K}$ in the sense of the supremum norm of $C[-\infty, \infty]$. It follows that $\lim_{t \rightarrow 0} \frac{2}{t^2}[C_D(t)(\tilde{f}_i)_{i \in \mathcal{K}} - (\tilde{f}_i)_{i \in \mathcal{K}}] = (\tilde{f}_i'')_{i \in \mathcal{K}}$ in the norm of \mathfrak{G}_k . Hence, $(f_i)_{i \in \mathcal{K}}$ belongs to the domain of the generator, say, G , of the cosine family $\{\text{Cos}_{A_c^{s-o}}(t), t \in \mathbb{R}\}$, and $G(f_i)_{i \in \mathcal{K}} = R(\tilde{f}_i'')_{i \in \mathcal{K}} = (f_i'')_{i \in \mathcal{K}} = A_c^{s-o}(f_i)_{i \in \mathcal{K}}$. On the other hand, $D(A_c^{s-o})$ cannot be a proper subset of the domain of G since A_c^{s-o} is a Feller generator and, in

particular, for $\lambda > 0$, $\lambda - A_c^{s-o}$ is injective and its range is \mathfrak{F}_k (see e.g. [6] p. 267). \square

Remark 1. A close inspection of the proof of Theorem 4.1 reveals that the space of extensions, that is, the range of E , is an invariant subspace for $\{C_D(t), t \in \mathbb{R}\}$. As restricted to this range, $\{C_D(t), t \in \mathbb{R}\}$ is a strongly continuous cosine family, and (4.16) says that $\{\text{Cos}_{A_c^{s-o}}, t \in \mathbb{R}\}$ is an isomorphic image of this cosine family.

5. Convergence of cosine families

It may be thought unclear how do we know, in Theorem 4.1, that $A_{\alpha(c)}^{\text{SP}}$ is a cosine family generator. The generation theorem for $A_{\alpha(c)}^{\text{SP}}$ can be proved directly, but can also be obtained as a by-product of Proposition 3.1, Theorem 3.2 and estimate (4.2). Indeed, as proved in [9, Chapter 60], if (4.2) holds, Proposition 3.1 implies existence of a strongly continuous cosine family in $C(K_{1,k})$ given by $\text{Cos}(t)f = \lim_{\varepsilon \rightarrow 0} \text{Cos}_{A_{\alpha(c)}^{s-o}}(t)f, t \in \mathbb{R}, f \in C(K_{1,k})$. Denoting by G the generator of this family we see also, by the Weierstrass formula, that $\lim_{\varepsilon \rightarrow 0} e^{tA_{\alpha(c)}^{s-o}}f = e^{tG}f, t \geq 0, f \in C(K_{1,k})$. Hence, by Theorem 3.2, we need to have $G = A_{\alpha(c)}^{\text{SP}}$, showing that $A_{\alpha(c)}^{\text{SP}}$ is a cosine family generator.

In this section, we want to argue that the abstract Kelvin formula (4.16) provides an additional insight into both the convergence theorem (Theorem 4.1) and the generation theorem for $A_{\alpha(c)}^{\text{SP}}$. Details are given in Theorem 5.1, below. Its notations involve the projection operator $\Pi : \mathfrak{F}_k \rightarrow \mathfrak{F}_k^0$ given by

$$\Pi(f_i)_{i \in \mathcal{K}} = \left(\sum_{j \in \mathcal{K}} \alpha_j f_j \right)_{i \in \mathcal{K}}$$

where $\alpha_i, i \in \mathcal{K}$ are defined in (4.3). We recall that in Step III of the proof of Lemma 4.2 we used Π to denote the operator $\Pi : \mathbb{R}^k \rightarrow \mathbb{R}^k$ which formally acts in the same way as the one introduced here; below, notationally we will not distinguish between these two operators either.

Theorem 5.1.

- (a) For $f \in C(K_{1,k})$, $\lim_{\varepsilon \rightarrow 0} \text{Cos}_{A_{\alpha(c)}^{s-o}}(t)f = \text{Cos}_{A_{\alpha(c)}^{\text{SP}}}(t)f$ uniformly in $t \in \mathbb{R}$.
- (b) For $f \in C(K_{1,k})$, $\lim_{\varepsilon \rightarrow 0} e^{tA_{\alpha(c)}^{s-o}}f = e^{tA_{\alpha(c)}^{\text{SP}}}f$ uniformly in $t \geq 0$.
- (c) The cosine family generated by $A_{\alpha(c)}^{\text{SP}}$ is given by the abstract Kelvin formula

$$\text{Cos}_{A_{\alpha(c)}^{\text{SP}}}(t) = RC_D(t)E, \quad t \in \mathbb{R}, \quad (5.1)$$

where $E : C(K_{1,k}) \stackrel{iz}{=} \mathfrak{F}_k^0 \rightarrow \mathfrak{G}_k$ maps a vector $(f_i)_{i \in \mathcal{K}} \in \mathfrak{F}_k^0$ to the vector $(\tilde{f}_i)_{i \in \mathcal{K}} \in \mathfrak{G}_k$ of extensions of f_i s given by $\tilde{f}_i(-x) = g_i(x), x \geq 0, i \in \mathcal{K}$ and

$$(g_i)_{i \in \mathcal{K}} = 2\Pi(f_i)_{i \in \mathcal{K}} - (f_i)_{i \in \mathcal{K}}. \quad (5.2)$$

Proof. Condition (b) is a direct consequence of (a) by the Weierstrass formula (see [14] for details, if necessary). Also, by Theorem 4.3, $\text{Cos}_{A_{i \in \mathcal{K}}^{\sigma(\epsilon)}}(t)$ is given by (4.16) with $E = E(\epsilon)$ defined in (4.9) and (4.11) with Q replaced by $\epsilon^{-1}Q$. Therefore, since we already know that the limit cosine family is generated by $A_{\alpha(c)}^{\text{SP}}$, to show (a) and (c) simultaneously it suffices to prove that, for any $(f_i)_{i \in \mathcal{K}}$,

$$I_\epsilon(t) := \epsilon^{-1} \int_0^t [e^{s\epsilon^{-1}Q}Q](f_i(t-s))_{i \in \mathcal{K}} ds$$

converges uniformly in $t \geq 0$ to $\Pi(f_i(t))_{i \in \mathcal{K}} - (f_i(t))_{i \in \mathcal{K}}$. In the special case of $f_i(x) = \text{const.}, x \geq 0, i \in \mathcal{K}$, this results is immediate, since then the integral is zero, and so is $\Pi(f_i(t))_{i \in \mathcal{K}} - (f_i(t))_{i \in \mathcal{K}}$. Therefore, we are left with proving this convergence for $(f_i)_{i \in \mathcal{K}}$ such that $f_i(0) = 0, i \in \mathcal{K}$.

Under this assumption, given $\epsilon > 0$ one can find a $\delta > 0$ such that $|f_i(s)| < \epsilon, i \in \mathcal{K}$ as long as $s < \delta$. Therefore, by (4.14), for $t \leq \delta$, $\|I_\epsilon(t)\| \leq \frac{\epsilon c M_0}{\epsilon} \int_0^t e^{-\epsilon^{-1}c\omega s} ds < \frac{\epsilon M_0}{\omega}$, and so

$$\|I_\epsilon(t) - \Pi(f_i(t))_{i \in \mathcal{K}} + (f_i(t))_{i \in \mathcal{K}}\| \leq (2 + \frac{M_0}{\omega})\epsilon, \quad t \in [0, \delta], \epsilon > 0. \quad (5.3)$$

Also, there is a δ_1 , and without loss of generality we can assume that $\delta_1 < \delta$, such that $|s| < \delta_1$ implies $|f_i(t-s) - f_i(t)| < \epsilon, i \in \mathcal{K}, t > \delta$, because $f_i, i \in \mathcal{K}$, being members of $C[0, \infty]$, are uniformly continuous. Hence, introducing $J_\epsilon(\delta_1, t) := \epsilon^{-1} \int_0^{\delta_1} [e^{s\epsilon^{-1}Q}Q](f_i(t))_{i \in \mathcal{K}} ds$, and arguing as above we obtain $\|I_\epsilon(\delta_1) - J_\epsilon(\delta_1, t)\| \leq \frac{\epsilon M_0}{\omega}$. At the same time, using estimate (4.14) again, $\|I_\epsilon(t) - I_\epsilon(\delta_1)\| \leq M_0 \|(f_i)_{i \in \mathcal{K}}\|_{\mathfrak{F}_k} e^{-\omega\epsilon^{-1}\delta_1}$. Hence, for $M_1 := \max(2 + \frac{M_0}{\omega}, M_0 \|(f_i)_{i \in \mathcal{K}}\|_{\mathfrak{F}_k})$,

$$\|I_\epsilon(t) - J_\epsilon(\delta_1, t)\| \leq M_1(\epsilon + e^{-\omega\epsilon^{-1}\delta_1}), \quad t \geq \delta, \epsilon > 0. \quad (5.4)$$

Finally, we have $J_\epsilon(\delta_1, t) = e^{\epsilon^{-1}\delta_1 Q}(f_i(t))_{i \in \mathcal{K}} - (f_i(t))_{i \in \mathcal{K}}$ and we know that (a) operators $e^{\epsilon^{-1}\delta_1 Q}, \epsilon > 0$ are contractions in \mathbb{R}^k (and thus are in particular equibounded) and $\lim_{\epsilon \rightarrow 0} e^{\epsilon^{-1}\delta_1 Q}v = \Pi v$ for any $v \in \mathbb{R}^k$, and (b) the set $K := \{u \in \mathbb{R}^k; v = (f_i(t))_{i \in \mathcal{K}} \text{ for some } t \geq \delta\}$ is compact in \mathbb{R}^k . It follows that for sufficiently small ϵ

$$\sup_{t \geq \delta} \|J_\epsilon(\delta_1, t) - \Pi(f_i(t))_{i \in \mathcal{K}} + (f_i(t))_{i \in \mathcal{K}}\| \leq \epsilon.$$

This, when combined with (5.3) and (5.4), shows that

$$\limsup_{\epsilon \rightarrow 0} \sup_{t \geq 0} \|I_\epsilon(t) - \Pi(f_i(t))_{i \in \mathcal{K}} + (f_i(t))_{i \in \mathcal{K}}\| \leq (M_1 + 1)\epsilon.$$

Since ϵ is arbitrary, the proof is complete. \square

We note that point (c) in the theorem just proved implies that each A_q^{SP} is a cosine family generator, as long as $\beta = 0$. Indeed, given $\alpha = (\alpha_i)_{i \in \mathcal{K}}$ with positive α_i such that $\sum_{i=1}^k \alpha_i$ we can take $c := (\alpha_i^{-1})_{i \in \mathcal{K}}$ and then $\alpha = \alpha(c)$.

It is also interesting to note that the proof of convergence of the integral $I_\epsilon(t)$ to $\Pi(f_i)_{i \in \mathcal{K}} - (f_i)_{i \in \mathcal{K}}$ carries out also to $(f_i)_{i \in \mathcal{K}} \in C(S_k) \setminus C(K_{1,k})$ except that than the limit function is not continuous at $t = 0$, and therefore

the limit cannot be uniform. Indeed, only in the first step of the proof, where we look at the case of constant functions, do we see a difference: in the case under consideration the constant depends on the edge, that is, we have $f_i(x) = u_i, x \geq 0, i \in \mathcal{K}$ where $u = (u_i)_{i \in \mathcal{K}} \in \mathbb{R}^k$. Hence, the integral equals $e^{tQ}u - u$, and this, for $t > 0$ converges to $\Pi u - u \neq 0$, whereas $e^{0Q}u - u = 0$. Here is an immediate corollary to this remark.

Corollary 5.2. *For $f \in C(S_k) \setminus C(K_{1,k})$, the limit $\lim_{\varepsilon \rightarrow 0} \text{Cos}_{A_{c(\varepsilon)}^{s-o}}(t)f$ exists for no $t \neq 0$.*

This result, which complements Thm. 5.1 (a), provides a much more specific information than the general theorem of [12], which says simply that there is at least one $t \neq 0$ for which the above limit does not exist.
