ABSTRACT

The Mixture-of-Experts (MoE) has gained increasing attention in studying Large Vision-Language Models (LVLMs). It uses a sparse model to replace the dense model, achieving comparable performance while activating fewer parameters during inference, thus significantly reducing the inference cost. Existing MoE methods in LVLMs encourage different experts to handle different tokens, and they usually employ a router to predict the routing of each token. However, the predictions are based solely on sample features and do not truly reveal the optimization directions of tokens. This may lead to severe optimization interference between different tokens assigned to an expert. To address this problem, this paper proposes a novel method based on token-level gradient analysis, *i.e.*, Solving Token Gradient Conflict (STGC). Specifically, we first use token-level gradients to identify *conflicting tokens* in experts. After that, we add a specialized loss tailored to eliminate conflicts among tokens within each expert. Our method can serve as a plug-in for diverse Large Vision-Language Models, and extensive experimental results demonstrate its effectiveness. The code will be publicly available at <https://github.com/longrongyang/STGC>.

1 INTRODUCTION

Large Vision-Language Models (LVLMs) have recently demonstrated significant advancements by integrating visual processing modules into Large Language Models (LLMs), bringing LLMs closer to Artificial General Intelligence. Many recent LVLM works (Zhang et al., 2023a; Bai et al., 2023b; Zhang et al., 2023b; Zhao et al., 2023; Chen et al., 2023b) show that large model size and large dataset size are especially important to enhance intelligence, *i.e.*, the scaling law. Even when the model size is sufficiently large, models exhibit "Emergent Abilities", which are not present in small models but are only present in large models. Thus, a series of studies (Li et al., 2022; Dai et al., 2023; Liu et al., 2023b) have expanded the capacity of LVLMs to 13 billion parameters, leading to state-of-the-art performance on various tasks.

Under realistic applications, deploying such large models requires considerable computational resources, making inference extremely expensive. For reducing the inference cost, a popular solution is using the Mixture-of-Experts (MoE) architecture. The MoE, a form of sparsely activated model, has been verified by many works (Fedus et al., 2022; Zoph et al., 2022; Komatsuzaki et al., 2022) to achieve comparable performance with dense models when activating fewer parameters.

With multiple experts in the MoE, a fundamental problem is the routing of tokens. To route tokens to different experts, existing MoE works (Lin et al., 2024; Dai et al., 2024) typically use a router, such as a linear layer, to predict the probability of each token belonging to different experts. The tokens are then dispatched to the expert with the Top- k predicted probability. Additionally, to prevent load imbalance, existing methods usually incorporate a load-balancing loss, which aims to prevent the overuse or underuse of some experts.

Beyond balancing the load, another important goal of routing tokens to different experts is to reduce interference among diverse data. To achieve this goal, some recent works have performed sample-

*Work done during an internship at Kuaishou Technology. †Correspondence to Xi Li.

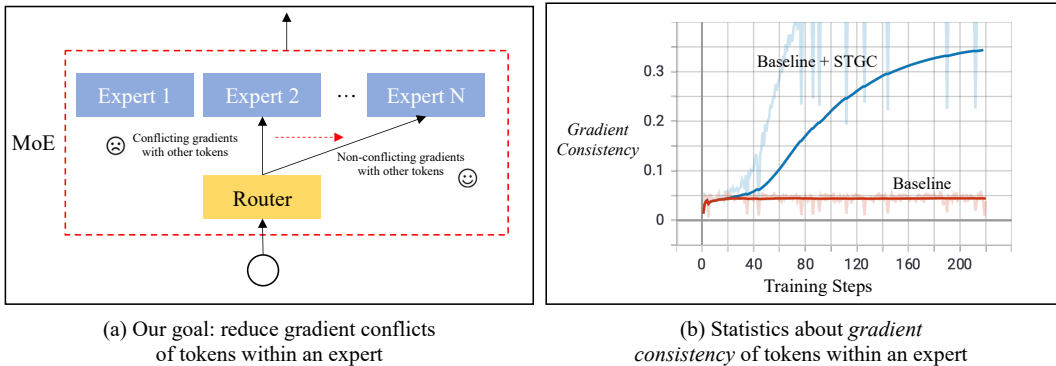

Figure 1: (a) In this work, our goal is to resolve interference among diverse data by reducing gradient conflicts among tokens within an expert. (b) We present statistics on the *gradient consistency* (the mean similarity among gradients of all tokens within an expert). By incorporating the proposed STGC, the *gradient consistency* increases, thereby verifying that STGC achieves our goal.

level clustering on instruction embeddings (Gou et al., 2023), grouping similar samples sent to the same expert. However, because routing during training is at the token level, existing methods struggle with interference between tokens within a sample. Meanwhile, samples with similar embeddings may have distinct optimization objectives, so embedding-based routing is still risky for generating optimization interference among tokens within an expert. Fortunately, the gradient can directly reveal the optimization direction. Therefore, in this work, we aim to explore data interference in the MoE through the lens of **token-level gradients**. As shown in fig. 1 (a), our basic idea is to reduce gradient conflicts of tokens within an expert, addressing severe data interference during the learning of LVLMs under complex and real-world scenarios.

To this end, we propose a novel regularization loss based on token-level gradients in this paper, for **Solving Token Gradient Conflict (STGC)**. The proposed STGC consists of two steps: Specifically: (i) *Conflicting Token Identification*. After processing a batch of data, we perform a backward pass to obtain the token-level gradients for each expert, without updating any model parameters. Within an expert, we define the average gradient of all tokens as the *average gradient*, representing the holistic optimization direction of the expert. Then, all tokens with gradients having negative cosine similarity to the *average gradient* are identified as *conflicting tokens*. (ii) *Conflict Elimination Loss*. For the *conflicting tokens*, we record their routing scores predicted by the router. We then reduce the routing probabilities of these tokens to other experts. As shown in fig. 1 (b), the proposed STGC makes the gradient directions of tokens within an expert become more consistent, *i.e.*, reduces the gradient conflicts of tokens within an expert.

In conclusion, our contribution can be summarized as:

- Beyond relying on sample-level cues, we propose using token-level gradients to identify optimization interference among tokens within an expert.
- We propose a novel conflict elimination loss to resolve gradient conflicts among tokens within an expert, making the gradient directions of tokens within an expert more consistent. This actually prompts the further specialization of experts.
- Designed as a plug-in, our method can be seamlessly integrated into existing Large Vision-Language Models (LVLMs). Extensive experiments confirm its effectiveness.

2 RELATED WORKS

2.1 LARGE VISION-LANGUAGE MODEL

Large Language Models (LLMs) have demonstrated strong instruction following and generalization capabilities. To maintain these capabilities while incorporating visual information, Large Vision-Language Models (LVLMs) such as GPT-4 and LLaVA utilize frozen visual encoders and trainable

visual projectors to integrate visual data into LLMs. They typically encode visual information into visual tokens and use these tokens to condition the adaptation of language tokens within LLMs (OpenAI, 2023; Touvron et al., 2023a; Wei et al., 2022; Touvron et al., 2023b; Zheng et al., 2023; Team, 2023; Sun et al., 2023; Du et al., 2021; Bai et al., 2023a; Yang et al., 2023; Penedo et al., 2023; Taori et al., 2023). Recent works have focused on improving performance through two types of methods. The first type optimizes training strategies, *e.g.*, (Bai et al., 2023b; Chen et al., 2023a). Most works belong to the second type, focusing on enhancing visual components, including expanding visual instruction-tuning datasets (Liu et al., 2023a; Zhang et al., 2023b), improving image encoders (Chen et al., 2023d; Bai et al., 2023b), and aligning the input and projection layers (Lin et al., 2023; Cha et al., 2023; Alayrac et al., 2022; Dai et al., 2023; Ye et al., 2023; Zhao et al., 2023). These efforts, particularly the expansion of visual instruction-tuning datasets and the increase in model scales, have significantly enhanced the visual understanding abilities of LVLMs.

2.2 MIXTURE-OF-EXPERTS (MOE)

The Mixture-of-Experts (MoE) is a hybrid model, consisting of multiple sub-models known as experts, and has shown potential in scaling up models (Shazeer et al., 2017). The key concept of MoE lies in the use of a router to determine the token set that each expert handles, aiming for reducing interference among tokens from different types of samples. Early MoE works have utilized the hard routing mode, where each expert is typically assigned a specific role. For example, a series of works (Bao et al., 2022; Long et al., 2023; Satar et al., 2022; Wang et al., 2022; Shen et al., 2023) consider language and vision gaps in multi-modal data (Liang et al., 2022), decoupling experts by modal category and assigning a specific role to each expert. The key feature of hard routers is that they eliminate the need to learn routing assignments. The hard routing has also been widely applied in task-specific MoEs (Li et al., 2023c; Zhu et al., 2022; Ma et al., 2023; Kudugunta et al., 2021).

Then, soft routers enable a dynamic allocation of tokens among different experts, allowing each expert to focus on its expertise and achieving model sparsity. Recent LLM (Shazeer et al., 2017; Lepikhin et al., 2020; Fedus et al., 2022; Zoph et al., 2022; Komatsuzaki et al., 2022) and LVLM works have mainly focused on soft routers. For instance, Gshard (Lepikhin et al., 2020) incorporates MoE into transformers and achieves excellent performance. Lifelong-MoE (Chen et al., 2023c) uses MoE to mitigate the challenge of catastrophic forgetting in lifelong learning. MoE-LLaVA (Lin et al., 2024) and LLaVA-MoE (Chen et al., 2024) utilize MoE and its variants to empower LVLMs. The approach of expert segmentation increases the number of experts to achieve greater specialization. DeepSeekMoE (Dai et al., 2024) and QwenMoE (Bai et al., 2023a) segment experts by splitting the FFN intermediate hidden dimension. Cluster-based methods, such as MoCLE (Gou et al., 2023), cluster samples and then route those in the same cluster to the same expert. DEMIX (Gururangan et al., 2021) clusters samples according to their task type, ensuring that samples in the same cluster are routed to the same expert. Existing methods primarily operate at the sample level and rely solely on either features or labels, which makes it challenging to address interference between different tokens within a sample. This work aims to utilize token-level gradients to identify and resolve token optimization interference within an expert in the MoE.

3 METHODOLOGY

3.1 OVERVIEW

Large Vision-Language Model: A Large Vision-Language Model (LVLM) aims to effectively integrate the capabilities of the pre-trained LLM and a visual model. Specifically, given a RGB image $\mathbf{v} \in \mathbb{R}^{H \times W \times 3}$, where H and W are its height and width, the vision encoder processes the input image to obtain a visual token sequence $\mathcal{Z} = [z_1, z_2, \dots, z_P] \in \mathbb{R}^{P \times C}$, where P is the sequence length of visual tokens, calculated as $P = \frac{H \times W}{14^2}$. A visual projection layer is then used to map $\mathcal{Z} \in \mathbb{R}^{P \times C}$ to $\mathcal{V} \in \mathbb{R}^{P \times D}$, where D represents the hidden layer size of Large Language Model (LLM). Similarly, the text undergoes word embedding by layer g and is projected to obtain the sequence tokens $\mathcal{T} = [t_1, t_2, \dots, t_N] \in \mathbb{R}^{N \times D}$, where N represents the sequence length of text tokens. Subsequently, the visual and text tokens are concatenated together and fed into a large language model. This model consists of stacked multi-head self-attention (MSA) and feed-forward neural networks

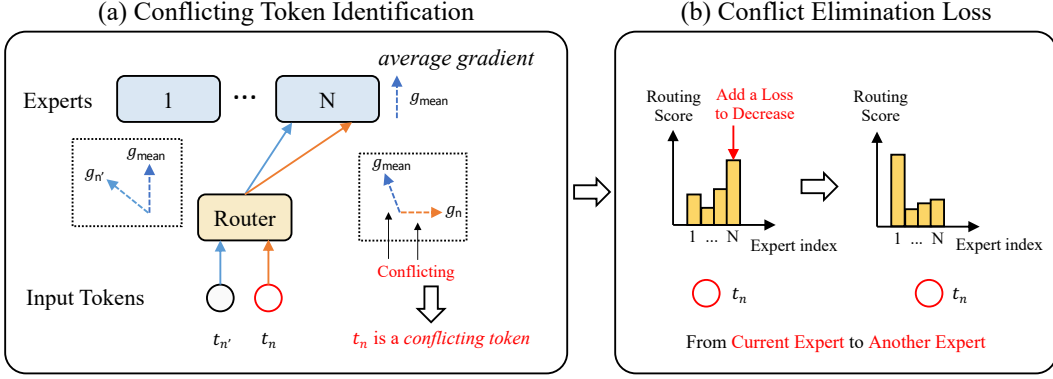

Figure 2: Our pipeline. (a) Conflicting Token Identification. When the gradient of a token has a sufficiently low cosine similarity to the *average gradient* of its assigned expert, this token is marked as a *conflicting token*. (b) Conflict Elimination Loss. We propose a loss term aimed at discouraging the routing of *conflicting tokens* to their assigned experts, achieved by reducing the routing scores for these tokens for their assigned experts.

(FFN), with layer normalization (LN) and residual connections typically used within each block:

$$\mathbf{x}_0 = [v_1, v_2, \dots, v_P, \dots, t_1, t_2, \dots, t_N], \quad (1)$$

$$\mathbf{x}'_\ell = \text{MSA}(\text{LN}(\mathbf{x}_{\ell-1})) + \mathbf{x}_{\ell-1}, \ell \in \{1, \dots, L\}, \quad (2)$$

$$\mathbf{x}_\ell = \text{FFN}(\text{LN}(\mathbf{x}'_\ell)) + \mathbf{x}'_\ell, \ell \in \{1, \dots, L\}, \quad (3)$$

$$\mathcal{Y} = \text{LN}(\mathbf{x}_L), \quad (4)$$

where L is the layer number of LLM. The LVLM model generates an output text sequence $\mathcal{Y} = [y_1, y_2, \dots, y_K] \in \mathbb{R}^{K \times D}$ by progressively generating each element, where $K = P + D$ represents the total length of the output text sequence. Then, the outputs are optimized through a generative loss in an auto-regressive manner. The loss is formulated as:

$$\mathcal{L}_{\text{main}} = - \sum_{i=1}^D \log p_\theta \left(\mathcal{Y}^{[P+i]} \mid \mathcal{Y}, \mathcal{T}^{[:i-1]} \right), \quad (5)$$

where θ is a trainable parameter. The auto-regressive loss for the token t_n is abbreviated as $\mathcal{L}_n(\theta)$.

MoE: The Mixture-of-Expert (MoE) layer is used to replace the FFN layer, *e.g.*, (Dai et al., 2024). A MoE layer consists of multiple FFNs, each representing an expert, *i.e.*, $\mathcal{E} = [e_1, e_2, \dots, e_E]$, where E is the number of experts. The router is typically a linear layer that predicts the probability of each token being assigned to each expert, and we formulate this process as:

$$p_{\text{moe}}(\mathbf{x})_i = \frac{e^{z_{\text{moe}}(\mathbf{x})_i}}{\sum_{j=1}^E e^{z_{\text{moe}}(\mathbf{x})_j}}, \quad (6)$$

where $z_{\text{moe}}(\mathbf{x}) = \mathbf{W} \cdot \mathbf{x}$ and $p_{\text{moe}}(\mathbf{x})_i$ is the routing score of \mathbf{x} for the i -th expert. The matrix $\mathbf{W} \in \mathbb{R}^{D \times E}$ represents the lightweight training parameters for routing. We calculate a weighted sum of the outputs from the Top- k experts with the highest softmax probabilities, where the weighting of each expert is related to the routing score:

$$w_{\text{moe}}(\mathbf{x})_i = \frac{e^{z_{\text{moe}}(\mathbf{x})_i}}{\sum_{j=1}^k e^{z_{\text{moe}}(\mathbf{x})_j}}, \quad (7)$$

$$\text{MoE}(\mathbf{x}) = \sum_{i=1}^k w_{\text{moe}}(\mathbf{x})_i \cdot e_i(\mathbf{x}),$$

where $w_{\text{moe}}(\mathbf{x})_i$ represents the weight of the i -th expert for \mathbf{x} , and $e_i(\mathbf{x})$ is the output of the i -th expert. We express $\mathcal{L}_n(\theta)$ as $\mathcal{L}_n(\theta_{e_i}, \theta')$, where θ_{e_i} denotes the i -th expert, and θ' represents all other parameters except for θ_{e_i} .

Our Method: In this work, our goal is to propose a novel learning strategy for the MoE architecture for reducing interference among diverse data. Specifically, as illustrated in Figure 2, we model the interference among tokens within an expert using token-level gradients, and then design a novel loss function that requires tokens with conflicting gradients to be handled by different experts. The details of these modules will be introduced in the subsequent sections.

3.2 CONFLICTING TOKEN IDENTIFICATION

For the MoE, the key to reducing interference among diverse data is to prevent optimization interference between tokens within an expert. A possible approach is to cluster samples based on their features, using the clustering results to decide which expert the samples should be assigned to. Alternatively, decisions can be made based on the specific task associated with each sample. However, these approaches have two main limitations: (i) They operate at the sample level, whereas the routing is at the token level; routing all tokens within a sample to the same expert does not effectively address interference between tokens within the sample. (ii) The optimization direction is jointly influenced by features and labels, but these methods rely on only one of these two factors. To address these issues, we propose using token-level gradients, which can accurately depict optimization directions at the token level, to identify optimization interference between tokens within an expert.

First, we introduce the negative impact brought by the gradient conflicts. Without loss of generality, we discuss two distinct text tokens, t_n and $t_{n'}$, as shown in Figure 2 (a). Assume that both t_n and $t_{n'}$ are processed by the expert e_i . Let $\mathbf{g}_n = \nabla_{\theta_{e_i}} \mathcal{L}_n(\theta_{e_i}, \theta')$ denote the gradient of the token t_n with respect to the expert θ_{e_i} . A small change in θ_{e_i} in the direction of $-\mathbf{g}_n$ is given by $\theta_{e_i} \leftarrow \theta_{e_i} - \delta \mathbf{g}_n$, with a step size δ . The effect of this change on the performance of another token $t_{n'}$ is measured by:

$$\Delta \mathcal{L}_{n'} = \mathcal{L}_{n'}(\theta_{e_i} - \delta \mathbf{g}_n, \theta') - \mathcal{L}_{n'}(\theta_{e_i}, \theta') = -\delta \mathbf{g}_n \cdot \mathbf{g}_{n'} + o(\delta), \quad (8)$$

where the second equality is obtained by first-order Taylor approximation. Likewise, the effect of an update of θ_{e_i} in the direction of the negative gradient of token n' (i.e., $-\mathbf{g}_{n'}$) on the performance of token n is $\Delta \mathcal{L}_i = -\delta \mathbf{g}_n \cdot \mathbf{g}_{n'} + o(\delta)$. Thus, the model update for token n is considered to negatively affect token n' when $\mathbf{g}_n \cdot \mathbf{g}_{n'} < 0$, since it increases the loss of token n' , and vice versa. We define \mathbf{g}_n and $\mathbf{g}_{n'}$ as conflicting gradients when their cosine similarity $\cos \phi_{nn'} < \tau$, where τ is a threshold and $\phi_{nn'}$ is the angle between \mathbf{g}_n and $\mathbf{g}_{n'}$. Gradient conflicts can cause the optimizer to struggle to converge to a desirable solution, especially when there is a large difference in gradient magnitudes.

We then define the *conflicting token*. The parameters of the expert e_i are updated using the *average gradient*. Let the tokens processed by the expert e_i be denoted as $\{t_1, \dots, t_{N_{e_i}}\}$, the *average gradient* on the expert e_i is represented as:

$$\mathbf{g}_{mean} = \frac{\sum_{n=1}^{N_{e_i}} \mathbf{g}_n}{N_{e_i}}. \quad (9)$$

The *average gradient* indicates the direction of parameter updates for the expert at each iteration. When the gradient of a token and the *average gradient* are conflicting gradients, it suggests that the token is detrimental to the learning of the expert e_i , so his token should be considered for assignment to another expert. A formal definition of a *conflicting token* is provided as follows:

Definition 1 (Conflicting Token) *The token t_n is said to a conflicting token if \mathbf{g}_n and \mathbf{g}_{mean} are conflicting gradients, where \mathbf{g}_{mean} is the average gradient of all tokens in the expert of t_n .*

Lastly, we detail our method for identifying *conflicting tokens*, as illustrated in Figure 2(a). Initially, we unfreeze only the expert layer in the MoE and compute the main loss. We then perform back-propagation to calculate the token-level gradients for each token within the expert layer. Subsequently, we calculate the *average gradient*, as well as the cosine similarity between the gradient of each token and the *average gradient*. Lastly, when the cosine similarity is less than τ , we mark the token as a *conflicting token*. Identifying these tokens allows us to use the precise optimization direction represented by the gradients to reduce interference among diverse data in the next section.

3.3 CONFLICT ELIMINATION LOSS

The learning of a *conflicting token* tends to increase the loss of most other tokens within its corresponding expert. Thus, once a *conflicting token* is identified, it should be reassigned to a different

expert for processing. To achieve this goal, we propose a simple yet effective regularization loss by constraining the routing scores predicted by the router, as shown in Figure 2(b).

Specifically, for each expert within every layer, we first identify the *conflicting tokens* using token-level gradients. Then, the router predicts the probability of each token being assigned to different experts. For a *conflicting token* t_n , we record the routing logits $z_{\text{moe}}(t_n)$, the routing scores $p_{\text{moe}}(t_n)$, and the expert ID id_{moe} it is currently assigned to. Using the expert ID id_{moe} , we calculate the loss:

$$\begin{aligned} z'_{\text{moe}}(t_n) &= -z_{\text{moe}}(t_n), \\ p'_{\text{moe}}(t_n)_i &= \frac{e^{z'_{\text{moe}}(t_n)_i}}{\sum_{j=1}^E e^{z'_{\text{moe}}(t_n)_j}}, \\ \mathcal{L}_{\text{token}} &= \frac{1}{N \cdot E} \sum_{n=1}^N \sum_{i=1}^E \log(p'_{\text{moe}}(t_n)_i) \cdot q_{\text{moe}}(t_n)_i, \end{aligned} \quad (10)$$

Where N is the count of all *conflicting tokens*, E is the number of experts, and $p'_{\text{moe}}(t_n)$ represents the inverted routing score for the token t_n . The $q_{\text{moe}}(t_n)$ define one-hot vectors, with $q_{\text{moe}}(t_n)_{id_{\text{moe}}} = 1$. This loss is designed to encourage the reassignment of *conflicting tokens* to different experts. When k in Top- k exceeds 1, a token may be assigned to multiple experts. Our method focuses on considering all tokens within each expert, regardless of whether a token has also been assigned to other experts.

3.4 TOTAL LOSS

To encourage experts to handle tokens in a balanced manner, the differentiable load balancing loss, as introduced in (Fedus et al., 2022), is typically defined for each MoE layer as follows:

$$\mathcal{L}_{\text{aux}} = E \cdot \sum_{i=1}^E \mathcal{F}_i \cdot \mathcal{P}_i, \quad (11)$$

where \mathcal{F} represents the fraction of tokens processed by each expert e_i , and \mathcal{P} represents the average routing probabilities assigned to expert e_i .

In conclusion, the total loss is given by:

$$\mathcal{L}_{\text{total}} = \mathcal{L}_{\text{main}} + \alpha \cdot \mathcal{L}_{\text{aux}} + \beta \cdot \mathcal{L}_{\text{token}}, \quad (12)$$

where α and β are hyper-parameters.

4 EXPERIMENTS

4.1 EXPERIMENTAL SETUP

Benchmark: In this work, we follow existing works (Liu et al., 2023c; Lin et al., 2024) to evaluate the proposed STGC. STGC is only used in the instruction tuning stage. Some academic-task-oriented and instruction-following benchmarks are collected for evaluating the LVLMs. For academic-task-oriented benchmarks, VQA-v2 (Goyal et al., 2017b) and GQA (Hudson & Manning, 2019) assess the visual perception capabilities of models through open-ended short answers. The VizWiz dataset (Gurari et al., 2018), containing 8,000 images, evaluates the zero-shot generalization of models on visual questions asked by visually impaired people. ScienceQA (Lu et al., 2022), a multiple-choice benchmark, evaluates the zero-shot generalization of models on scientific question answering. TextVQA (Singh et al., 2019a) focuses on text-rich visual question answering tasks. ChartQA (Masry et al., 2022) focuses on visual and logical reasoning tasks over charts through open-ended short answers. DocVQA (Mathew et al., 2021) focuses on reading comprehension tasks over document images through open-ended short answers.

For instruction-following benchmarks, POPE (Li et al., 2023b) evaluates the degree of hallucination in model responses on three sampled subsets of COCO (Lin et al., 2014): Random, Common, and Adversarial. MME (Fu et al., 2023) assesses the visual perception of models with yes/no questions. MMBench (Liu et al., 2023d) evaluates the robustness of model answers with all-round shuffling on

Table 1: **Comparison among different LVLMs on image understanding benchmarks.** “Act.”, “V”, “Q”, “P”, “M”, and “S” represent activated parameters, Vicuna (Chiang et al., 2023), Qwen (Bai et al., 2023a), Phi-2 (Microsoft, 2023), MobileLLaMA (Chu et al., 2023), and StableLM (Team), respectively. Evaluation Benchmarks include VQA^{v2} (Goyal et al., 2017a); GQA (Hudson & Manning, 2019); VisWiz (Gurari et al., 2018); SQA^I: ScienceQA-IMG (Lu et al., 2022); VQA^T: TextVQA (Singh et al., 2019b); POPE (Li et al., 2023a); MME (Fu et al., 2023); MMB: MMBench (Liu et al., 2023d); MM-Vet (Yu et al., 2023a); AI2D (Kembhavi et al., 2016); ChartQA (Masry et al., 2022); DocVQA (Mathew et al., 2021). * indicates that there is some overlap in the training data. † indicates that a stronger visual encoder (siglip-so400m-patch14-384) is used. All “Sparse Model” methods employ the configure 4-Top-2.

multiple choice answers. MM-Vet (Yu et al., 2023b) evaluates the model capabilities in engaging in visual conversations on a diverse range of tasks, and evaluates the correctness and helpfulness of the responses using the GPT-4 evaluation framework. AI2D (Kembhavi et al., 2016), a multiple-choice benchmark, evaluates the model capabilities for science diagram comprehension.

Baseline: Our main baseline is set to MoE-LLaVA (Lin et al., 2024) in this paper. MoE-LLaVA incorporates a Mixture-of-Experts (MoE) into LVLMs, and has proposed a three-stage training scheme. It trains only the MoE in the third stage, *i.e.*, the instruction tuning stage. MoE-LLaVA has 4 experts and selects the Top-2 experts to handle tokens, and we refer to this configuration as 4-Top-2. Building on MoE-LLaVA, we add a novel regularization loss $\mathcal{L}_{\text{token}}$ in this work during the instruction tuning stage to enhance the MoE. For the language model backbone, we follow MoE-LLaVA (Lin et al., 2024) to use StableLM-1.6B and Phi2-2.7B. The visual encoder is typically set as clip-vit-large-patch14-336. α is set to 0.01, following MoE-LLaVA (Lin et al., 2024). We also compare with DYNMOE-LLaVA (Guo et al., 2024), which improves the MoE-LLaVA by dynamically setting the selected expert count during inference.

4.2 IMAGE UNDERSTANDING EVALUATION

Image Question Answering: We evaluate the performance of our method on five image question-answering benchmarks, as shown in Table 1, and report the number of activated parameters as a measure of efficiency. Our method demonstrates superior image understanding capabilities, achieving the 80.0%, 63.0%, 48.6%, 70.9%, and 58.8% performance on VQA^{v2}, GQA, VisWiz, SQA^I, and VQA^T, respectively. Compared to LLaVA-1.5 with 7B activated parameters, our method brings 0.6%, 1.0%, 4.1%, and 0.8% performance increase on VQA^{v2}, GQA, SQA^I, and VQA^T, respectively, when only activating 3.6B parameters.

Benchmark Toolkit: To comprehensively evaluate the multi-modal understanding capabilities of our method, we assess its performance across four benchmark toolkits. These toolkits typically involve open-ended answers and serve as tools to verify the model ability to engage in natural language questioning. As shown in Table 1, our method demonstrates superior image understanding capabilities, achieving the 86.5%, 1481.7, 71%, and 40.7% performance on VQA^{v2}, GQA, VisWiz, SQA^I, and VQA^T, respectively. Compared to LLaVA-1.5 with 7B activated parameters, our method brings 0.6%, 7.6%, and 10.2% performance increase on POPE, MMB, and MM-Vet, respectively, when only activating 3.6B parameters.

Table 2: **STGC as a plug-in.** We set different baselines and add the proposed STGC. 4-Top-1 means that 4 experts are set and the Top-1 expert is selected to handle tokens. * indicates that there is some overlap in the training data. † indicates that a stronger visual encoder (siglip) is used.

Method	LLM	Act.	VQA ^{v2}	GQA	VisWiz	SQA ^I	VQA ^T	POPE	MME	MMB	MM-Vet	Avg

4.3 ABLATION STUDY

STGC as a plug-in: We design the proposed STGC as a plug-in for existing MoE methods. To fully verify the robustness and effectiveness of the proposed STGC, we select different baselines, including different MoE configures (4-Top-2 & 4-Top-1), LLMs (S-1.6B & P-2.7b), and visual encoders (clip & siglip). Then, we add STGC onto these baselines. As shown in table 2, under diverse baselines, adding STGC always brings a stable and convincing performance increase.

Study about Conflicting Token Identification: Our method uses token-level gradients as the cue to identify *conflicting tokens*. To verify the superiority of token-level gradients as the cue over sample-level embeddings, we conduct experiments: (i) Sample-level expert labels, based on clustering for instruction embeddings, which is similar to (Chen et al., 2024). (ii) Token-level expert labels, based on the token-level gradients in each expert. Besides, when the gradient \mathbf{g}_n of the token t_n and the *average gradient* \mathbf{g}_{mean} satisfy the condition $\cos \phi_{nmean} < \tau$, we flag the token as a *conflicting token*. We discuss different thresholds for identifying *conflicting tokens*: $\tau \in \{0.1, 0.0, -0.1\}$.

As shown in Table 3, we find: (i) The performance using token-level gradients to identify *conflicting tokens* is significantly higher than using sample-level embedding clusters. For example, our method achieves a 4.8% higher performance improvement over the embedding-based scheme on GQA. (ii) When $\tau = 0$, the performance on most datasets is the best. The results are consistent with the common belief, *i.e.*, gradients are considered conflicting when their cosine similarity is less than 0.

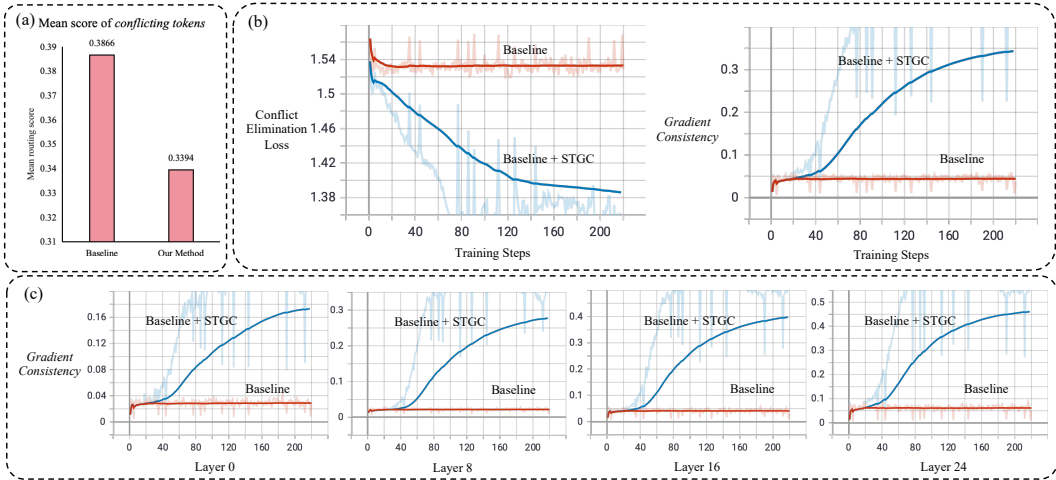

Figure 3: **Statistical Verification.** We conduct a deep analysis of the role of STGC. “Baseline” means MoE-LLaVA. “Baseline + STGC” means our method. (a) We present the change of routing scores of *conflicting tokens* on their current experts, to verify that STGC is moving *conflicting tokens* away from their current experts. (b) We compute a novel metric, *gradient consistency* (the mean similarity among gradients of all tokens within an expert), for verifying that the decrease of the proposed loss leads to the more consistent token gradients within an expert. (c) We further analyze the *gradient consistency* on different layers.

Table 5: **Scalability of STGC.** We consider to employ the larger scale of data. Under more data, the STGC can bring the more significant performance increase.

Method	LLM	Data	VQA ^{v2}	GQA	VisWiz	SQA ¹	VQA ^T	POPE	MME	MMB	MM-Vet	Avg
MoE-LLaVA-4-Top-2 [†] +STGC	P-2.7B	665K	79.9*	62.6*	43.7	70.3	57.0	85.7	1431.3	68.0	35.9	62.9
	P-2.7B	665K	80.3*	63.2*	45.1	70.3	57.4	86.1	1447.6	69.7	35.7	63.5
MoE-LLaVA-4-Top-2 [†] +STGC	P-2.7B	1021K	79.7*	63.0*	42.7	71.1	56.9	84.3	1439.9	70.4	42.2	63.8
	P-2.7B	1021K	80.0*	63.0*	48.6	70.9	58.8	86.5	1481.7	71.0	40.7	64.9

Study about Conflict Elimination Loss: We propose the Conflict Elimination Loss to reduce interference among diverse data types. We explore the impact of applying the loss at different layers, with a total of 24 layers: (i) All layers (0-23). (ii) The second half of the layers (12-23). (iii) The first half of the layers (0-11). We also consider different loss weightings $\beta \in \{0.5, 1.0, 2.0\}$.

As shown in Table 4, we find: (i) Applying the proposed loss to all layers yields the best performance on most datasets, verifying its importance across all layers. (ii) The proposed loss is not sensitive to different loss weightings β , with the highest performance on most datasets when β is set as 1.0.

Scalability of STGC: One necessary hypothesis of this work is that there are severe optimization interference among diverse training data. Therefore, STGC should bring a more significant performance increase when using a more complex dataset to train. To verify this, we expand the size of the public dataset we are using for further experiments. Specifically, we use the training data provided in Open-LLaVA-NeXT*, *i.e.*, open-llava-next_instruct_mix1M. As shown in table 5, under more data, STGC brings a more significant average performance increase (1.1% vs. 0.6%).

Statistical Verification: The main claim of this work is that STGC can effectively reduce the gradient conflicts of tokens within an expert, *i.e.*, making the gradient directions of tokens within an expert more consistent, thus decreasing data interference and improving model performance. To verify this, we design a statistical verification experiment. In this experiment, the training consists of two steps: The first step is to capture the gradient similarities of tokens within an expert. In detail, we gather all tokens within an expert e_i and compute their cosine similarity to form a similarity

*<https://github.com/xiaoachen98/Open-LLaVA-NeXT>

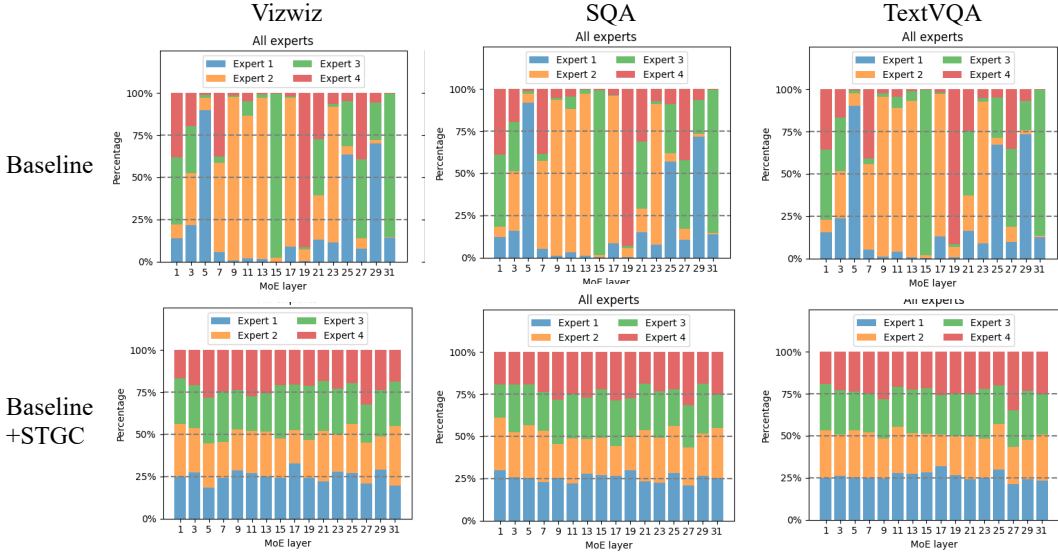

Figure 4: **Expert Loading.** We select three validation datasets, *i.e.*, VizWiz (Gurari et al., 2018), SQA (Lu et al., 2022), and TextVQA (Singh et al., 2019a), to analyze the expert loading. “Baseline” means MoE-LLaVA. “Baseline + STGC” means our method.

matrix. Then, we compute the mean of the similarity matrix as $\text{mean}(\cos \phi_i)$. We define the average of $\text{mean}(\cos \phi_i)$ on all experts as *gradient consistency*, serving as a novel metric to evaluate whether the gradient directions are consistent within an expert. The second step is to update models. In this experiment, we only use the proposed loss to update parameters, for undisturbedly observing the impact of the proposed loss to the *gradient consistency*.

We first provide the change in routing scores of *conflicting tokens* on their corresponding experts in fig. 3 (a). Then, we provide the curve graph of the proposed loss and the *gradient consistency* obtained from the TensorBoard dashboard in fig. 3 (b). We also provide the *gradient consistency* on different layers; The total layer number is 32, and we analyze the layers $\{0, 8, 16, 24\}$. We find: (i) Our method significantly reduces the mean routing score from 0.3866 to 0.3349, verifying that our method encourages *conflicting tokens* to be assigned to other experts instead of the current ones. (ii) By reducing the mean routing score of *conflicting tokens*, the *gradient consistency* significantly improves, indicating that the token gradient directions within an expert become more consistent. This verifies the role of STGC in reducing gradient conflicts. (iii) For different layers, STGC always increases the *gradient consistency*. The deeper layers seem to have higher *gradient consistency* after adding STGC while the shallower layers have lower *gradient consistency*.

Expert Loading: We present some statistical results about the expert loading during inference on several datasets. As shown in fig. 4, STGC benefits the expert load balance. A possible reason is that the expert load imbalance means that many tokens are routed to an expert, significantly increasing the possibility that tokens have gradient conflicts. By adding STGC, many tokens are moved to the expert with fewer tokens. This may also be a new perspective on why the expert load balance is important to the MoE system.

5 CONCLUSION

Our study reveals that there is still severe optimization interference of tokens within an expert for the MoE, leading to sub-optimal learning for the experts. To reduce optimization interference among tokens, we propose employing token-level gradients to identify *conflicting tokens*, and then adding a novel conflict elimination loss based on the routing scores. Our method acts as a plug-in, which can be easily integrated into existing MoE-based LLMs. Extensive experiments demonstrate the superior performance of our approach across diverse datasets. Especially when the data diversity is larger, our method brings a more significant performance increase.
