# Study of semileptonic $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays based on the $\mathrm{SU}(3)$ flavor symmetry 

Ru-Min Wang ${ }^{1, \dagger}$, Yi-Jie Zhang ${ }^{1}$, Meng-Yuan Wan ${ }^{1}$, Xiao-Dong Cheng ${ }^{2, \S}$, Yuan-Guo Xu ${ }^{1, \sharp}$<br>${ }^{1}$ College of Physics and Communication Electronics, JiangXi Normal University, NanChang, JiangXi 330022, China<br>${ }^{2}$ College of Physics and Electronic Engineering, Xinyang Normal University, Xinyang, Henan 464000, China<br>$\dagger_{\text {ruminwang@sina.com }} \S_{\text {chengxd }}$ @mails.ccnu.edu.cn $\quad \#_{\text {yuanguoxu@jxnu.edu.cn }}$

Decays $B \rightarrow D P \ell^{+} \nu_{\ell}(\ell=e, \mu, \tau)$ with the non-resonance, the charmed vector resonances, the charmed scalar resonances and the charmed tensor resonances are calculated by using the $\mathrm{SU}(3)$ flavor symmetry. Firstly, the decay amplitudes of different modes are related by the $\operatorname{SU}(3)$ flavor symmetry. Then, relevant experiential data are used to constrain nonperturbative coefficients in the non-resonant and various resonant $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays. Finally, using the constrained nonperturbative coefficients, the branching ratios of not-yet-measured $B \rightarrow D^{*} P \ell^{+} \nu_{\ell}$ decays with the non-resonant and various charmed resonant contributions are predicted. Many branching ratios are predicted for the first time. We find that $B \rightarrow D \eta^{\prime} \ell^{+} \nu_{\ell}, B_{s} \rightarrow D_{s} \eta^{\prime} \ell^{+} \nu_{\ell}$ decays only receive the non-resonant contributions, $B \rightarrow D_{s} K \ell^{+} \nu_{\ell}, B_{s} \rightarrow D K \ell^{+} \nu_{\ell}, B \rightarrow D \eta \ell^{+} \nu_{\ell}$ and $B_{s} \rightarrow D_{s} \eta \ell^{+} \nu_{\ell}$ decays receive both non-resonant and charmed tensor resonant contributions, $B^{+} \rightarrow D^{-} \pi^{+} \ell^{+} \nu_{\ell}$ decays receive the non-resonant, the charmed scalar resonant and the charmed tensor resonant contributions, and other $B \rightarrow D \pi \ell^{+} \nu_{\ell}$ decays receive all four kinds of contributions. These results can be used to test the $\mathrm{SU}(3)$ flavor symmetry approach in the four-body semileptonic decays by the future LHCb and Belle-II experiments.

## I. Introduction

Semileptonic $B$ decays play a key role in testing the Standard Model and understanding the heavy quark dynamics. Some three-body semileptonic $B$ decays, such as $B \rightarrow D \ell^{+} \nu_{\ell}$ and $B \rightarrow D^{*} \ell^{+} \nu_{\ell}$, have been well understood. Nevertheless, other decays, like $B \rightarrow D_{0} \ell^{+} \nu_{\ell}, B \rightarrow D_{2}^{*} \ell^{+} \nu_{\ell}$ and $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays, received less attention. Some branching ratios of the $B \rightarrow D P \ell^{\prime+} \nu_{\ell^{\prime}}\left(\ell^{\prime}=e, \mu\right)$ decays have been measured, and the experimental data from the Particle Data Group (PDG) within $2 \sigma$ errors are [1]

$$
\begin{align*}
\mathcal{B}\left(B^{+} \rightarrow D^{-} \pi^{+} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{T} & =(4.4 \pm 0.8) \times 10^{-3},  \tag{1}\\
\mathcal{B}\left(B^{+} \rightarrow D^{-} \pi^{+} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{\bar{D}_{0}} & =(2.5 \pm 1.0) \times 10^{-3},  \tag{2}\\
\mathcal{B}\left(B^{+} \rightarrow D^{-} \pi^{+} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{\bar{D}_{2}^{*}} & =(1.53 \pm 0.32) \times 10^{-3},  \tag{3}\\
\mathcal{B}\left(B^{0} \rightarrow D^{0} \pi^{-} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{T} & =(4.1 \pm 1.0) \times 10^{-3},  \tag{4}\\
\mathcal{B}\left(B^{0} \rightarrow D^{0} \pi^{-} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{D_{0}} & =(3.0 \pm 2.4) \times 10^{-3},  \tag{5}\\
\mathcal{B}\left(B^{0} \rightarrow D^{0} \pi^{-} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{D_{2}^{*}} & =(1.21 \pm 0.66) \times 10^{-3},  \tag{6}\\
\mathcal{B}\left(B^{+} \rightarrow D_{s}^{-} K^{+} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{T} & =\left(3.0_{-2.4}^{+2.8}\right) \times 10^{-4}, \tag{7}
\end{align*}
$$

where $\mathcal{B}_{T, M}$ denote the total and $M$ resonant branching ratios. For $\mathcal{B}\left(B^{+} \rightarrow D^{-} \pi^{+} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{T}$ and $\mathcal{B}\left(B^{0} \rightarrow\right.$ $\left.D^{0} \pi^{-} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{T}$ given in Eq. (1) and Eq. (4), the PDG reports decays via the $D_{0}$ and $D_{2}^{*}$ resonances. With the experiment running, more relevant decays could be measured at LHCb and Belle-II. Present measurements of the $B \rightarrow D P \ell^{\prime+} \nu_{\ell^{\prime}}$ decays give us an opportunity to test theoretical approaches of the $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays and to predict many non-measured decays, which can be further tested by LHCb and Belle-II in the near future.

Theoretically, semileptonic decays are relatively simple, since the weak and strong dynamics can be separated in these decays. All the strong dynamics in the initial and final hadrons is included in the hadronic transition form factors. The analytic structure of the $B \rightarrow D P$ form factors is more complicated than ones of the $B \rightarrow D$ or $B \rightarrow P$ form factors [2]. Due to our poor understanding of hadronic interactions, the $B \rightarrow D P$ evaluations of the form factors are difficult. In the absence of reliable calculations, the symmetry analysis can provide very useful information about the decays. $\mathrm{SU}(3)$ flavor symmetry is one of popular symmetry approaches. $\mathrm{SU}(3)$ flavor symmetry has been widely used to study hadron decays, including $b$-hadron decays [3-16], c-hadron decays [15-31], and light hadron decays $[15,32-37]$. $\mathrm{SU}(3)$ flavor breaking effects due to the mass difference of $u, d, s$ quarks have also been studied, for instance, in Refs. [38-50].

Some four-body semileptonic decays $B / D \rightarrow P P \ell^{+} \nu_{\ell}$ and $B \rightarrow D^{(*)} P \ell^{+} \nu_{\ell}$ have been studied, for instance, in Refs. [2, 51-64]. In this work, we will study the $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays with the non-resonant, the charmed vector resonant, the charmed scalar resonant and the charmed tensor resonant contributions by the $\mathrm{SU}(3)$ flavor symmetry based on the experimental data. Firstly, we will construct the hadronic amplitude relations or the form factor relations between different decay modes. Then, we will use the available data to extract the hadronic amplitudes or the form factors. Finally, we will predict the not-yet-measured modes for further tests in experiments.

This paper is organized as follows. The non-resonant contributions of the $B \rightarrow D P \ell \nu_{\ell}$ decays are discussed in Sec. II. The charmed vector resonant, the charmed scalar resonant and the charmed tensor resonant contributions of $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays are presented in Sec. III. Finally, summary is given in Sec. IV.

## II. Non-resonant $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays

## A. Meson multiplets

Since the $\mathrm{SU}(3)$ flavor analysis is based on the $\mathrm{SU}(3)$ flavor group, we give relevant meson multiplets first. Bottom pseudoscalar triplet $B_{i}$, charm pseudoscalar triplet $D_{i}$, charm scalar triplet $D_{0 i}$ and charm vector triplet $D_{i}^{*}$ under the $\mathrm{SU}(3)$ flavor symmetry of $u, d, s$ quarks are

$$
\begin{align*}
B_{i} & =\left(B^{+}(\bar{b} u), B^{0}(\bar{b} d), B_{s}^{0}(\bar{b} s)\right), & D_{i} & =\left(\bar{D}^{0}(\bar{c} u), D^{-}(\bar{c} d), D_{s}^{-}(\bar{c} s)\right)  \tag{8}\\
D_{0 i} & =\left(\bar{D}_{0}^{0}(\bar{c} u), D_{0}^{-}(\bar{c} d), D_{s 0}^{-}(\bar{c} s)\right), & D_{i}^{*} & =\left(\bar{D}^{* 0}(\bar{c} u), D^{*-}(\bar{c} d), D_{s}^{*-}(\bar{c} s)\right) \tag{9}
\end{align*}
$$

where $i=1,2,3$ for $u, d, s$ quarks. Note that the structures of scalar $D_{0}$ mesons are not known well, and they might be four-quark states, $D_{0 i}^{4 q}=\left(\bar{D}_{0}^{0}(\bar{c} u \bar{d} d), D_{0}^{-}(\bar{c} d \bar{u} u), D_{s 0}^{-}(\bar{c} s(\bar{u} u+\bar{d} d) / \sqrt{2})\right)$ [65].

The charm tensor triplet $D_{2 i}^{*}$ is

$$
\begin{equation*}
D_{2 i}^{*}=\left(\bar{D}_{2}^{*}(2460)^{0}, D_{2}^{*}(2460)^{-}, D_{s 2}^{*}(2573)^{-}\right) \tag{10}
\end{equation*}
$$

Note that $D_{0 i}, D_{i}^{*}$ and $D_{2 i}^{*}$ will be used for the resonances in Sec. III, and they are given here together. In addition, charm axial vector mesons $D_{1}^{\prime} / D_{1}$ have been studied in Ref. [66] for $B \rightarrow D^{*} P \ell^{+} \nu_{\ell}$ decays, $D_{1}^{\prime} / D_{1}$ do not contribute to $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays, so relevant multiplets are not listed here. Light pseudoscalar octets and singlets $P_{j}^{i}$ is

$$
P_{j}^{i}=\left(\begin{array}{ccc}
\frac{\pi^{0}}{\sqrt{2}}+\frac{\eta_{8}}{\sqrt{6}}+\frac{\eta_{1}}{\sqrt{3}} & \pi^{+} & K^{+}  \tag{11}\\
\pi^{-} & -\frac{\pi^{0}}{\sqrt{2}}+\frac{\eta_{8}}{\sqrt{6}}+\frac{\eta_{1}}{\sqrt{3}} & K^{0} \\
K^{-} & \bar{K}^{0} & -\frac{2 \eta_{8}}{\sqrt{6}}+\frac{\eta_{1}}{\sqrt{3}}
\end{array}\right)
$$

with $j=1,2,3$ for $u, d, s$ quarks. The $\eta$ and $\eta^{\prime}$ are mixtures of $\eta_{1}=\frac{u \bar{u}+d \bar{d}+s \bar{s}}{\sqrt{3}}$ and $\eta_{8}=\frac{u \bar{u}+d \bar{d}-2 s \bar{s}}{\sqrt{6}}$ with the mixing angle $\theta_{P}$

$$
\binom{\eta}{\eta^{\prime}}=\left(\begin{array}{cc}
\cos \theta_{P} & -\sin \theta_{P}  \tag{12}\\
\sin \theta_{P} & \cos \theta_{P}
\end{array}\right)\binom{\eta_{8}}{\eta_{1}}
$$

And $\theta_{P}=\left[-20^{\circ},-10^{\circ}\right]$ from the PDG [1] will be used in our numerical analysis.

## B. Decay amplitudes

The four-body semileptonic $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays are generated by $\bar{b} \rightarrow \bar{c} \ell^{+} \nu_{\ell}$ transition, and the effective Hamiltonian is

$$
\begin{equation*}
\mathcal{H}_{e f f}\left(\bar{b} \rightarrow \bar{c} \ell^{+} \nu_{\ell}\right)=\frac{G_{F}}{\sqrt{2}} V_{c b} \bar{b} \gamma^{\mu}\left(1-\gamma_{5}\right) \bar{c} \overline{\nu_{\ell}} \gamma_{\mu}\left(1-\gamma_{5}\right) \ell \tag{13}
\end{equation*}
$$

where $G_{F}$ is the Fermi constant, and $V_{c b}$ is the CKM matrix element. Decay amplitudes of the $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays can be written as

$$
\begin{align*}
\mathcal{A}\left(B \rightarrow D P \ell^{+} \nu_{\ell}\right) & =\left\langle D\left(k_{1}\right) P\left(k_{2}\right) \ell^{+}\left(q_{1}\right) \nu_{\ell}\left(q_{2}\right)\right| \mathcal{H}_{e f f}\left(\bar{b} \rightarrow \bar{c} \ell^{+} \nu_{\ell}\right)\left|B\left(p_{B}\right)\right\rangle \\
& =\frac{G_{F}}{\sqrt{2}} V_{c b} L_{\mu} H^{\mu} \tag{14}
\end{align*}
$$

where $L_{\mu}=\overline{\nu_{\ell}} \gamma_{\mu}\left(1-\gamma_{5}\right) \ell$ is the leptonic charged current, and $H^{\mu}=\left\langle D\left(k_{1}\right) P\left(k_{2}\right)\right| \bar{c} \gamma^{\mu}\left(1-\gamma_{5}\right) \bar{b}\left|B\left(p_{B}\right)\right\rangle$ is the hadronic matrix element. Usually, the hadronic matrix element $H^{\mu}$ can be obtained in terms of the form factors $F_{\perp, t, 0, \|}$ of the $B \rightarrow D P$ transitions, which are similar to ones of $B \rightarrow P P$ transitions [64]. Nevertheless, the calculations of the $F_{0}, F_{t}, F_{\perp}, F_{\|}$form factors are very difficult. In this work, the hadronic matrix element will be related by the $\mathrm{SU}(3)$ flavor symmetry.

Since the leptonic charged current $L_{\mu}$ is invariant under the $\mathrm{SU}(3)$ flavor symmetry, the hadronic matrix element $H^{\mu}$ can be parameterized by the $\mathrm{SU}(3)$ flavor symmetry. Then the decay amplitudes of the non-resonant $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays in Eq. (14) can be transformed as

$$
\begin{align*}
\mathcal{A}\left(B \rightarrow D P \ell^{+} \nu_{\ell}\right)_{N} & =\frac{G_{F}}{\sqrt{2}} V_{c b}^{*} H(B \rightarrow D P)_{N} \bar{\nu}_{\ell} \gamma_{\mu}\left(1-\gamma_{5}\right) \ell  \tag{15}\\
H(B \rightarrow D P)_{N} & =c_{01} B^{i} P_{i}^{j} D_{j}+c_{02} B^{i} D_{i} P_{k}^{k} \tag{16}
\end{align*}
$$

where $c_{01,02}$ are the nonperturbative coefficients under the $\mathrm{SU}(3)$ flavor symmetry. The $c_{02}$ term is suppressed by the Okubo-Zweig-Iizuka (OZI) rule [67-69], and it only appears in the decays with $\eta, \eta^{\prime}$ final states.

TABLE I: SU(3) IRA amplitudes for $B \rightarrow D P \ell^{+} \nu$ decays due to $\bar{b} \rightarrow \bar{c} \ell^{+} \nu$.

| Decay modes | Non-resonant decay amplitudes | Decay modes | Non-resonant decay amplitudes |
| :---: | :---: | :---: | :---: |
| $B^{+} \rightarrow D^{-} \pi^{+} \ell^{+} \nu_{\ell}$ | $c_{01}$ | $B^{0} \rightarrow D^{-} \pi^{0} \ell^{+} \nu_{\ell}$ | $-\frac{1}{\sqrt{2}} c_{01}$ |
| $B^{+} \rightarrow D_{s}^{-} K^{+} \ell^{+} \nu_{\ell}$ | $c_{01}$ | $B^{0} \rightarrow D^{-} \eta \ell^{+} \nu_{\ell}$ | $\frac{c_{01} \cos \theta_{P}}{\sqrt{6}}-\frac{\left(c_{01}+3 c_{02}\right) \sin \theta_{P}}{\sqrt{3}}$ |
| $B^{+} \rightarrow \bar{D}^{0} \pi^{0} \ell^{+} \nu_{\ell}$ | $\frac{1}{\sqrt{2}} c_{01}$ | $B^{0} \rightarrow D^{-} \eta^{\prime} \ell^{+} \nu_{\ell}$ | $\frac{c_{01} \sin \theta_{P}}{\sqrt{6}}+\frac{\left(c_{01}+3 c_{02}\right) \cos \theta_{P}}{\sqrt{3}}$ |
| $B^{+} \rightarrow \bar{D}^{0} \eta \ell^{+} \nu_{\ell}$ | $\frac{c_{01} \cos \theta_{P}}{\sqrt{6}}-\frac{\left(c_{01}+3 c_{02}\right) \sin \theta_{P}}{\sqrt{3}}$ | $B_{s}^{0} \rightarrow \bar{D}^{0} K^{-} \ell^{+} \nu_{\ell}$ | $c_{01}$ |
| $B^{+} \rightarrow \bar{D}^{0} \eta^{\prime} \ell^{+} \nu_{\ell}$ | $\frac{c_{01} \sin \theta_{P}}{\sqrt{6}}+\frac{\left(c_{01}+3 c_{02}\right) \cos \theta_{P}}{\sqrt{3}}$ | $B_{s}^{0} \rightarrow D^{-} \bar{K}^{0} \ell^{+} \nu_{\ell}$ | $c_{01}$ |
| $B^{0} \rightarrow \bar{D}^{0} \pi^{-} \ell^{+} \nu_{\ell}$ | $c_{01}$ | $B_{s}^{0} \rightarrow D_{s}^{-} \eta \ell^{+} \nu_{\ell}$ | $-\frac{2 c_{01} \cos \theta_{P}}{\sqrt{6}}-\frac{\left(c_{01}+3 c_{02}\right) \sin \theta_{P}}{\sqrt{3}}$ |
| $B^{0} \rightarrow D_{s}^{-} K^{0} \ell^{+} \nu_{\ell}$ | $c_{01}$ | $B_{s}^{0} \rightarrow D_{s}^{-} \eta^{\prime} \ell^{+} \nu_{\ell}$ | $-\frac{2 c_{01} \sin \theta_{P}}{\sqrt{6}}+\frac{\left(c_{01}+3 c_{02}\right) \cos \theta_{P}}{\sqrt{3}}$ |

The idiographic hadronic amplitudes of the non-resonant $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays are given in Tab. I. From Tab. I, one can see that, if ignoring the OZI suppressed $c_{02}$ term, all hadronic amplitudes can be related by only one nonperturbative coefficient $c_{01}$.

The differential branching ratios of the nonresonant $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays are [64]

$$
\begin{equation*}
\frac{d \mathcal{B}\left(B \rightarrow D P \ell^{+} \nu_{\ell}\right)_{N}}{d q^{2} d k^{2}}=\frac{1}{2} \tau_{B}|\mathcal{N}|^{2} \beta_{\ell}\left(3-\beta_{\ell}\right)\left|H_{N}\right|^{2} \tag{17}
\end{equation*}
$$

with

$$
\begin{align*}
|\mathcal{N}|^{2} & =G_{F}^{2}\left|V_{c b}\right|^{2} \frac{\beta_{\ell} q^{2} \sqrt{\lambda}}{3 \times 2^{10} \pi^{5} m_{B}^{3}}, \quad \text { with } \quad \beta_{\ell}=1-\frac{m_{\ell}^{2}}{q^{2}} \\
\left|H_{N}\right|^{2} & =\left|F_{0}\right|^{2}+\frac{2}{3}\left(\left|F_{\|}\right|^{2}+\left|F_{\perp}\right|^{2}\right)+\frac{3 m_{\ell}^{2}}{q^{2}\left(3-\beta_{\ell}\right)}\left|F_{t}\right|^{2} \tag{18}
\end{align*}
$$

where $\tau_{M}\left(m_{M}\right)$ is lifetime(mass) of $M$ particle. The ranges of integration are given by $\left(m_{D}+m_{P}\right)^{2} \leq k^{2} \leq\left(m_{B}-m_{\ell}\right)^{2}$ and $m_{\ell}^{2} \leq q^{2} \leq\left(m_{B}-\sqrt{k^{2}}\right)^{2}$. If we ignore $\left|F_{t}\right|^{2}$ term since it is proportional to $m_{\ell}^{2}$ and it is small when $\ell=e, \mu$, $\left|H_{N}\right|^{2}$ is only include the hadronic part. Noted that although $\left|F_{t}\right|^{2}$ term might be large when $\ell=\tau$, it is difficult to estimate its contribution in this work, so we still ignore it. Then $H_{N}$, which only includes hadronic part, follow the relationship of the $\mathrm{SU}(3)$ flavor symmetry in the Tab. I.

## C. Numerical results

For the non-resonant $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays, no any process has been measured until now. However, as given in Eq. (7), $\mathcal{B}\left(B^{+} \rightarrow D_{s}^{-} K^{+} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{T}$ has been measured. The $B^{+} \rightarrow D_{s}^{-} K^{+} \ell^{\prime+} \nu_{\ell^{\prime}}$ mode can decay via the non-resonance and the $D_{2}^{*}$ tensor meson resonance. In the later analysis of Sec. III, the contributions of $D_{2}^{*}$ tensor meson resonance are far less than the experimental data given in Eq. (7). So we think that the non-resonant contributions are dominant in the $B^{+} \rightarrow D_{s}^{-} K^{+} \ell^{\prime+} \nu_{\ell^{\prime}}$ decays, i.e., $\mathcal{B}\left(B^{+} \rightarrow D_{s}^{-} K^{+} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N} \approx \mathcal{B}\left(B^{+} \rightarrow D_{s}^{-} K^{+} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{T}$. The experimental data of $\mathcal{B}\left(B^{+} \rightarrow D_{s}^{-} K^{+} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{T}$ are used to determine $c_{01}$ in the non-resonant $B \rightarrow D P \ell^{+} \nu_{\ell^{\prime}}$ decays (Due to poor relevant experimental data, the OZI suppressed $c_{02}$ term is ignored). Then many other branching ratios of the non-resonant $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays can be predicted by using the data of $\mathcal{B}\left(B^{+} \rightarrow D_{s}^{-} K^{+} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{T}$, which are listed in the second column of Table II.

From the second column of Table II, one can see that many branching ratio central values of the non-resonant $B \rightarrow D P \ell^{\prime+} \nu_{\ell^{\prime}}$ decays, such as $\mathcal{B}\left(B^{+} \rightarrow D^{-} \pi^{+} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}, \mathcal{B}\left(B^{+} \rightarrow \bar{D}^{0} \pi^{0} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}, \mathcal{B}\left(B^{+} \rightarrow \bar{D}^{0} \eta \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}, \mathcal{B}\left(B^{0} \rightarrow\right.$ $\bar{D}^{0} \pi^{-} \ell^{\prime+} \nu_{\ell^{\prime}} \mathcal{B}\left(B^{0} \rightarrow D_{s}^{-} K^{0} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}, \mathcal{B}\left(B^{0} \rightarrow D^{-} \pi^{0} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}, \mathcal{B}\left(B^{0} \rightarrow D^{-} \eta \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}, \mathcal{B}\left(B_{s}^{0} \rightarrow \bar{D}^{0} K^{-} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}$ $\mathcal{B}\left(B_{s}^{0} \rightarrow D^{-} \bar{K}^{0} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}$ and $\mathcal{B}\left(B_{s}^{0} \rightarrow D_{s}^{-} \eta \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}$, are on the orders of $10^{-4}$, which could be measured by the LHCb and Belle II experiments. Nevertheless, other decays, for examples, the non-resonant $B^{+} \rightarrow \bar{D}^{0} \eta^{\prime} \ell^{\prime+} \nu_{\ell^{\prime}}$, $B^{0} \rightarrow D^{-} \eta^{\prime} \ell^{\prime+} \nu_{\ell^{\prime}}, B_{s}^{0} \rightarrow D_{s}^{-} \eta^{\prime} \ell^{\prime+} \nu_{\ell^{\prime}}$, and all $B \rightarrow D P \tau^{+} \nu_{\tau}$ decays, are strongly suppressed by the narrow phase spaces, their branching ratio central values are on the orders of $\mathcal{O}\left(10^{-5}-10^{-7}\right)$, and they might not be observed by the experiments in the near future.

TABLE II: Branching ratios for $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays due to $\bar{b} \rightarrow \bar{c} \ell^{+} \nu_{\ell}$ within $2 \sigma$ errors. The unit is $10^{-3}$ for the branching ratios. $\mathcal{B}_{N}$ denotes the resonant branching ratios, $\mathcal{B}_{[R]}$ denotes the $R$ resonant branching ratios, ${ }^{e}$ denotes experimental data within $2 \sigma$ errors, and ${ }^{\dagger}$ denotes the results obtained by considering the resonance width effects.

## III. Decays $B \rightarrow D P \ell^{+} \nu_{\ell}$ with the $D^{*}, D_{0}, D_{2}^{*}$ resonances

For the $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays with the resonances, in the case of the decay widths of the resonance states are very narrow, the resonant branching ratios respect a simple factorization relation

$$
\begin{equation*}
\mathcal{B}\left(B \rightarrow D_{J} \ell^{+} \nu_{\ell}, D_{J} \rightarrow D P\right)=\mathcal{B}\left(B \rightarrow D_{J} \ell^{+} \nu_{\ell}\right) \times \mathcal{B}\left(D_{J} \rightarrow D P\right) \tag{19}
\end{equation*}
$$

where $D_{J}=D^{*}, D_{0}, D_{2}^{*}$. And this result is also a good approximation for wider resonances. Eq. (19) will be used in our analysis for resonant $B \rightarrow D_{J}(\rightarrow D P) \ell^{+} \nu_{\ell}$ decays. Relevant $\mathcal{B}\left(B \rightarrow D_{J} \ell^{+} \nu_{\ell}\right)$ and $\mathcal{B}\left(D_{J} \rightarrow D P\right)$ also can be obtained by the $\mathrm{SU}(3)$ flavor symmetry.

## A. Semileptonic three-body $B \rightarrow D_{J} \ell^{+} \nu_{\ell}$ decays

The helicity amplitudes of the decays $B \rightarrow D_{J} \ell^{+} \nu_{\ell}$ can be written as

$$
\begin{equation*}
\mathcal{M}\left(B \rightarrow D_{J} \ell^{+} \nu_{\ell}\right)=\frac{G_{F}}{\sqrt{2}} V_{c b} \sum_{m m^{\prime}} g_{m m^{\prime}} L_{m}^{\lambda_{\ell} \lambda_{\nu}} H_{m^{\prime}}^{\lambda_{M}} \tag{20}
\end{equation*}
$$

with

$$
\begin{align*}
L_{m}^{\lambda_{\ell} \lambda_{\nu}} & =\epsilon_{\alpha}(m) \overline{\nu_{\ell}} \gamma^{\alpha}\left(1-\gamma_{5}\right) \ell  \tag{21}\\
H_{m^{\prime}}^{\lambda_{D_{J}}} & =\epsilon_{\beta}^{*}\left(m^{\prime}\right)\left\langle D_{J}\left(p, \epsilon^{*}\right)\right| \bar{c} \gamma^{\beta}\left(1-\gamma_{5}\right) b\left|B\left(p_{B}\right)\right\rangle \tag{22}
\end{align*}
$$

where the particle helicities $\lambda_{D_{J}}=0$ for $D / D_{0}^{*}, \lambda_{D_{J}}=0, \pm 1$ for $D_{J}=D^{*} / D_{2}^{*}, \lambda_{\ell}= \pm \frac{1}{2}, \lambda_{\nu}=+\frac{1}{2}$, and $\epsilon_{\mu}(m)$ is the polarization vectors of the virtual $W$ with $m=0, t, \pm 1$.

The matrix elements can be parameterized via the form factors of the $B \rightarrow D_{J}$ transitions [70, 71]

$$
\begin{align*}
\langle D(p)| \bar{c} \gamma_{\mu} b\left|B\left(p_{B}\right)\right\rangle= & f_{1}^{B D}\left(q^{2}\right)\left(\left(p+p_{B}\right)_{\mu}-\frac{m_{B}^{2}-m_{D}^{2}}{q^{2}} q_{\mu}\right)+f_{0}^{B D}\left(q^{2}\right) \frac{m_{B}^{2}-m_{D}^{2}}{q^{2}} q_{\mu},  \tag{23}\\
\left\langle D_{0}^{*}(p)\right| \bar{c} \gamma_{\mu} \gamma_{5} b\left|B\left(p_{B}\right)\right\rangle= & -i\left[f_{1}^{B D_{0}}\left(q^{2}\right)\left(\left(p+p_{B}\right)_{\mu}-\frac{m_{B}^{2}-m_{D_{0}}^{2}}{q^{2}} q_{\mu}\right)+f_{0}^{B D_{0}}\left(q^{2}\right) \frac{m_{B}^{2}-m_{D_{0}}^{2}}{q^{2}} q_{\mu}\right],  \tag{24}\\
\left\langle D^{*}\left(p, \varepsilon^{*}\right)\right| \bar{c} \gamma_{\mu}\left(1-\gamma_{5}\right) b\left|B\left(p_{B}\right)\right\rangle= & \frac{2 V^{B D^{*}}\left(q^{2}\right)}{m_{B}+m_{D^{*}}} \epsilon_{\mu \nu \alpha \beta} \varepsilon^{* \nu} p_{B}^{\alpha} p^{\beta} \\
& -i\left[\varepsilon_{\mu}^{*}\left(m_{B}+m_{D^{*}}\right) A_{1}^{B D^{*}}\left(q^{2}\right)-\left(p_{B}+p\right)_{\mu}\left(\varepsilon^{*} \cdot p_{B}\right) \frac{A_{2}^{B D^{*}}\left(q^{2}\right)}{m_{B}+m_{D^{*}}}\right] \\
& +i q_{\mu}\left(\varepsilon^{*} \cdot p_{B}\right) \frac{2 m_{D^{*}}}{q^{2}}\left[A_{3}^{B D^{*}}\left(q^{2}\right)-A_{0}^{B D^{*}}\left(q^{2}\right)\right],  \tag{25}\\
\left\langle D_{2}\left(p, \varepsilon^{*}\right)\right| \bar{c} \gamma_{\mu}\left(1-\gamma_{5}\right) b\left|B\left(p_{B}\right)\right\rangle= & \frac{2 i V^{B D_{2}}\left(q^{2}\right)}{m_{B}+m_{D_{2}}} \epsilon_{\mu \nu \alpha \beta}^{* \nu} p_{B}^{\alpha} p^{\beta} \\
& +2 m_{D_{2}} \frac{e^{*} \cdot q}{q^{2}} q_{\mu} A_{0}^{B D_{2}}\left(q^{2}\right)+\left(m_{B}+m_{D_{2}}\right)\left(e_{\mu}^{*}-\frac{e^{*} \cdot q}{q^{2}} q_{\mu}\right) A_{1}^{B D_{2}}\left(q^{2}\right) \\
& -\frac{e^{*} \cdot q}{m_{B}+m_{D_{2}}}\left(\left(p_{B}+p\right)_{\mu}-\frac{m_{B}^{2}-m_{D_{2}}^{2}}{q^{2}} q_{\mu}\right) A_{2}^{B D_{2}}\left(q^{2}\right), \tag{26}
\end{align*}
$$

where $s=q^{2}\left(q=p_{B}-p_{M}\right), \varepsilon^{*}$ is the polarization of vector meson, and $e^{* \nu} \equiv \frac{\varepsilon^{* \mu \nu} \cdot p_{B \mu}}{m_{B}}, f_{+, 0}^{B D}, f_{1,0}^{B D_{0}}$
The hadronic helicity amplitudes can be written as

$$
\begin{equation*}
H_{ \pm}^{D}=0, \quad H_{0}^{D}=\frac{2 m_{B}\left|\vec{p}_{D}\right|}{\sqrt{q^{2}}} f_{+}^{B D}\left(q^{2}\right), \quad H_{t}^{D}=\frac{m_{B}^{2}-m_{D}^{2}}{\sqrt{q^{2}}} f_{0}^{B D}\left(q^{2}\right) \tag{27}
\end{equation*}
$$

for $B \rightarrow D \ell^{+} \nu_{\ell}$ decays,

$$
\begin{equation*}
H_{ \pm}^{D_{0}}=0, \quad H_{0}^{D_{0}}=\frac{i 2 m_{B}\left|\vec{p}_{D_{0}}\right|}{\sqrt{q^{2}}} f_{1}^{B D_{0}}\left(q^{2}\right), \quad H_{t}^{D_{0}}=\frac{i\left(m_{B}^{2}-m_{D_{0}}^{2}\right)}{\sqrt{q^{2}}} f_{0}^{B D_{0}}\left(q^{2}\right) \tag{28}
\end{equation*}
$$

for $B \rightarrow D_{0} \ell^{+} \nu_{\ell}$ decays,

$$
\begin{align*}
H_{ \pm}^{D^{*}} & =\left(m_{B}+m_{D^{*}}\right) A_{1}^{B D^{*}}\left(q^{2}\right) \mp \frac{2 m_{B}\left|\vec{p}_{D^{*}}\right|}{\left(m_{B}+m_{D^{*}}\right)} V^{B D^{*}}\left(q^{2}\right)  \tag{29}\\
H_{0}^{D^{*}} & =\frac{1}{2 m_{D^{*}} \sqrt{q^{2}}}\left[\left(m_{B}^{2}-m_{D^{*}}^{2}-q^{2}\right)\left(m_{B}+m_{D^{*}}\right) A_{1}^{B D^{*}}\left(q^{2}\right)-\frac{4 m_{B}^{2}\left|\vec{p}_{D^{*}}\right|^{2}}{m_{B}+m_{D^{*}}} A_{2}^{B D^{*}}\left(q^{2}\right)\right]  \tag{30}\\
H_{t}^{D^{*}} & =\frac{2 m_{B}\left|\vec{p}_{D^{*}}\right|}{\sqrt{q^{2}}} A_{0}^{B D^{*}}\left(q^{2}\right) \tag{31}
\end{align*}
$$

for $B \rightarrow D^{*} \ell^{+} \nu_{\ell}$ decays, and

$$
\begin{align*}
H_{ \pm}^{D_{2}^{*}} & =\frac{2\left|\vec{p}_{D_{2}^{*}}\right|}{2 \sqrt{2} m_{D_{2}^{*}}}\left[\left(m_{B}+m_{D_{2}^{*}}\right) A_{1}^{B D_{2}^{*}}\left(q^{2}\right) \mp \frac{2 m_{B}\left|\vec{p}_{D_{2}^{*}}\right|}{\left(m_{B}+m_{D_{2}^{*}}\right)} V^{B D_{2}^{*}}\left(q^{2}\right)\right]  \tag{32}\\
H_{0}^{D_{2}^{*}} & =\frac{\left|\vec{p}_{D_{2}^{*}}\right|}{\sqrt{2} m_{D_{2}^{*}}} \frac{1}{2 m_{D_{2}^{*}} \sqrt{q^{2}}}\left[\left(m_{B}^{2}-m_{D_{2}^{*}}^{2}-q^{2}\right)\left(m_{B}+m_{D_{2}^{*}}\right) A_{1}^{B D_{2}^{*}}\left(q^{2}\right)-\frac{4 m_{B}^{2}\left|\vec{p}_{D_{2}^{*}}\right|^{2}}{m_{B}+m_{D_{2}^{*}}} A_{2}^{B D_{2}^{*}}\left(q^{2}\right)\right]  \tag{33}\\
H_{t}^{D_{2}^{*}} & =\frac{\left|\vec{p}_{D_{2}^{*}}\right|}{\sqrt{2} m_{D_{2}^{*}}} \frac{2 m_{B}\left|\vec{p}_{D_{2}^{*}}\right|}{\sqrt{q^{2}}} A_{0}^{B D_{2}^{*}}\left(q^{2}\right) \tag{34}
\end{align*}
$$

for $B \rightarrow D_{2}^{*} \ell^{+} \nu_{\ell}$ decays, where $\left|\vec{p}_{D_{J}}\right| \equiv \sqrt{\lambda\left(m_{B}^{2}, m_{D_{J}}^{2}, q^{2}\right)} / 2 m_{B}$ with $\lambda(a, b, c)=a^{2}+b^{2}+c^{2}-2 a b-2 a c-2 b c$.
The differential branching ratios of the $B \rightarrow D_{J} \ell^{+} \nu_{\ell}$ decays are [72]

$$
\begin{equation*}
\frac{d \mathcal{B}\left(B \rightarrow D_{J} \ell^{+} \nu_{\ell}\right)}{d q^{2}}=\frac{\tau_{B} G_{F}^{2}\left|V_{c b}\right|^{2} \lambda^{1 / 2}\left(q^{2}-m_{\ell}^{2}\right)^{2}}{24(2 \pi)^{3} m_{B}^{3} q^{2}} \mathcal{H}_{\text {total }} \tag{35}
\end{equation*}
$$

with

$$
\begin{align*}
\mathcal{H}_{\text {total }} & =\left(\mathcal{H}_{U}+\mathcal{H}_{L}\right)\left(1+\frac{m_{\ell}^{2}}{2 q^{2}}\right)+\frac{3 m_{\ell}^{2}}{2 q^{2}} \mathcal{H}_{S}  \tag{36}\\
\mathcal{H}_{U} & =\left|H_{+}^{D_{J}}\right|^{2}+\left|H_{-}^{D_{J}}\right|^{2}, \quad \mathcal{H}_{L}=\left|H_{0}^{D_{J}}\right|^{2}, \quad \mathcal{H}_{S}=\left|H_{t}^{D_{J}}\right|^{2} \tag{37}
\end{align*}
$$

where $\lambda \equiv \lambda\left(m_{B}^{2}, m_{D_{J}}^{2}, q^{2}\right)$ and $m_{\ell}^{2} \leq q^{2} \leq\left(m_{B}-m_{D_{J}}\right)^{2}$.
Now one can obtain the branching ratios of the $B \rightarrow D_{J} \ell^{+} \nu_{\ell}$ decays by the relevant form factors, which depend on the different methods. In this work, we use the $\mathrm{SU}(3)$ flavor symmetry to obtain the relations of the hadronic helicity amplitudes, and the same relations are also true for the form factors. In terms of the $\mathrm{SU}(3)$ flavor symmetry, the hadronic helicity amplitudes can be parameterized as

$$
\begin{equation*}
H_{m^{\prime}}^{\lambda_{D_{J}}}=C_{0}^{D_{J}} B_{i}\left(D_{J}\right)^{i} \tag{38}
\end{equation*}
$$

where $C_{0}^{D_{J}}$ are the nonperturbative coefficients of the $B \rightarrow D_{J} \ell^{+} \nu_{\ell}$ decays under the $\mathrm{SU}(3)$ flavor symmetry. For the charmed four-quark states $D_{0}^{4 q}, H_{m^{\prime}}^{\lambda_{D_{0}}}=C_{0}^{4 q, D_{0}} B_{i}\left(D_{J}\right)_{j}^{i j}$. And the hadronic helicity amplitude relations for the $B \rightarrow D_{J} \ell^{+} \nu_{\ell}$ decays are summarized in Tab. III.

The relations in Tab. III will be used for the form factors $F(0)$, which are $f_{1}^{B D}(0)$ in the $B \rightarrow D \ell^{+} \nu_{\ell}$ decays, $V^{B D^{*}}(0)$ in the $B \rightarrow D^{*} \ell^{+} \nu_{\ell}$ decays, $f_{1}^{B D_{0}}(0)$ in the $B \rightarrow D_{0} \ell^{+} \nu_{\ell}$ decays, and $A_{1}^{B D_{2}^{*}}(0)$ in $B \rightarrow D_{2}^{*} \ell^{+} \nu_{\ell}$ decays. The form factors $F(0)$ are determined by the relevant experimental data. Other form factors $F_{i}(0)$ can be expressed as $r_{i} \times F(0)$, and the values of the ratios $r_{i}=\frac{F_{i}(0)}{F(0)}$ are taken from Ref. [73] for the $B \rightarrow D / D^{*} \ell^{+} \nu_{\ell}$ decays, from Ref.

| $\mathcal{B}\left(B_{s}^{0} \rightarrow D_{s 0}^{-} \tau^{+} \nu_{\tau}\right)$ | $\ldots$ | $6.75 \pm 2.40^{2 q}, 13.50 \pm 4.80^{4 q}$ | $\mathcal{B}\left(B_{s}^{0} \rightarrow D_{s 2}^{-} \tau^{+} \nu_{\tau}\right)$ | $\ldots$ | $1.73 \pm 0.38$ |

[75] for the $B \rightarrow D_{0} \ell^{+} \nu_{\ell}$ decays and from Ref. [76] for the $B \rightarrow D_{2}^{*} \ell^{+} \nu_{\ell}$ decays. Taking the $B \rightarrow D^{*} \ell^{+} \nu_{\ell}$ decays as an example, there are four form factors $V^{B D^{*}}(0)$ and $A_{0,1,2}^{B D^{*}}(0)$ in the $B \rightarrow D^{*} \ell^{+} \nu_{\ell}$ decays, $A_{0,1,2}^{B D^{*}}(0)$ are expressed by $r_{0,1,2} \times V^{B D^{*}}(0)$, and the values of $r_{0,1,2}=\frac{A_{0,1,2}^{B D^{*}}(0)}{V^{B D^{*}}(0)}$ are taken from Ref. [73], and then there is only one parameter $V^{B D^{*}}(0)$ in the $B \rightarrow D^{*} \ell^{+} \nu_{\ell}$ decays, and it can be determined by the experimental data of the $B \rightarrow D^{*} \ell^{+} \nu_{\ell}$ decays.

Now we give our branching ratio predictions of the semileptonic $B \rightarrow D_{J} \ell^{+} \nu_{\ell}$ decays under the $\mathrm{SU}(3)$ flavor symmetry. If not specially specified, the theoretical input parameters, such as the lifetimes, the masses, and the experimental data within the $2 \sigma$ error bars from PDG [1] will be used in our numerical analysis.

Theoretically, exclusive semileptonic $B \rightarrow D / D^{*} \ell^{+} \nu_{\ell}$ are well understood. Although the $B \rightarrow D \ell^{+} \nu_{\ell}$ decays are not used for the four-body semileptonic decay branching ratios, there are five experimental data in the $B \rightarrow D \ell^{+} \nu_{\ell}$
decays, which could be used to test the $\mathrm{SU}(3)$ flavor symmetry approach, so we present their results here. The experimental data of the $B \rightarrow D \ell^{+} \nu_{\ell}$ decays are listed in the second column of Tab. IV, which are used to constrain the only one free parameter $f_{1}^{B D}(0)$. We obtain that $f_{1}^{B D}(0)=0.66 \pm 0.05$, which agrees with 0.67 given in Ref. [73]. Then one can predict the branching ratios of the $B_{s}^{0} \rightarrow D_{s}^{-} \ell^{+} \nu_{\ell}$ decays in terms of the constrained $f_{1}^{B D}(0)$, which are listed in the third column of Tab. IV.

For the $B \rightarrow D^{*} \ell^{+} \nu_{\ell}$ decays, there are also five measured modes, and they are listed in the fifth column of Tab. IV. $\mathcal{B}\left(B^{+} \rightarrow \bar{D}^{* 0} \tau^{+} \nu_{\tau}\right)$ and $\mathcal{B}\left(B^{0} \rightarrow D^{*-} \tau^{+} \nu_{\tau}\right)$ are not used to constrain the only free parameter $V^{B D^{*}}(0)$. We obtain that $V^{B D^{*}}(0)=0.65 \pm 0.05$ from three experimental data of $\mathcal{B}\left(B_{(s)} \rightarrow D^{*} \ell^{\prime+} \nu_{\ell^{\prime}}\right)$, which is smaller than 0.76 given in Ref. [73]. Then one can predict other branching ratios of the $B \rightarrow D^{*} \ell^{+} \nu_{\ell}$ decays, which are listed in the last column of Tab. IV. One can see that our prediction and experimental data of $\mathcal{B}\left(B^{+} \rightarrow \bar{D}^{* 0} \tau^{+} \nu_{\tau}\right)$ intersect within $2 \sigma$ error ranges, nevertheless, our prediction of $\mathcal{B}\left(B^{0} \rightarrow D^{*-} \tau^{+} \nu_{\tau}\right)$ is slightly smaller than its data, and they will agree within $3 \sigma$ error ranges.

For the $B \rightarrow D_{0} \ell^{+} \nu_{\ell}$ decays, only two decay modes have been measured, and they are listed in the second column of Tab. V, which are used to constrain the parameter $f_{1}^{B D_{0}}(0)$. Our constrained $f_{1}^{B D_{0}}(0)=0.38 \pm 0.09$, which is obviously larger than $0.27 \pm 0.03$ given in Ref. [75]. Our branching ratio predictions of the semileptonic $B \rightarrow D_{0} \ell^{+} \nu_{\ell}$ decays are listed in the third column of Tab. V. The branching ratio predictions of $B_{s}^{0} \rightarrow D_{s 0}^{-} \ell^{+} \nu_{\ell}$ are different between the two quark state and the four quark state, the prediction with four quark state are 2 times of one with the two quark state. In the later analysis of $B \rightarrow D P \ell \nu_{\ell}$ with $D_{0}$ resonances, the results of the two quark state will be used.

For the $B \rightarrow D_{2}^{*} \ell^{+} \nu_{\ell}$ decays, only $\mathcal{B}\left(B^{+} \rightarrow \bar{D}_{2}^{0} \ell^{\prime+} \nu_{\ell^{\prime}}\right)$ and $\mathcal{B}\left(B^{0} \rightarrow D_{2}^{-} \ell^{\prime+} \nu_{\ell^{\prime}}\right)$ have been measured, and they are listed in the fifth column of Tab. V. We obtain $A_{1}^{B D_{2}^{*}}(0)=0.46 \pm 0.06$ from two measured branching ratios, which are consistent with $0.63_{-0.12}^{+0.11}$ within $2 \sigma$ errors given in Ref. [76]. Then one can predict the branching ratios of the semileptonic $B \rightarrow D^{*} \ell^{+} \nu_{\ell}$ decays, which are listed in the last column of Tab. IV. Decays $B_{s}^{0} \rightarrow D_{s 2}^{-} \ell^{+} \nu_{\ell}$ have been calculated by the QCD sum rule approach for different scale parameter $\mu=2 / 3 / 4 \mathrm{GeV}$ [77], for examples, $\mathcal{B}\left(B_{s}^{0} \rightarrow D_{s 2}^{-} \ell^{\prime+} \nu_{\ell^{\prime}}\right)=(3.07 \pm 1.40) \times 10^{-3}$ and $\mathcal{B}\left(B_{s}^{0} \rightarrow D_{s 2}^{-} \tau^{+} \nu_{\tau}\right)=(1.03 \pm 0.61) \times 10^{-3}$ for $\mu=4 \mathrm{GeV}$. The predictions of $\mathcal{B}\left(B_{s}^{0} \rightarrow D_{s 2}^{-} \ell^{\prime+} \nu_{\ell^{\prime}}\right)$ in Ref. [77] are consistent with ours, nevertheless, the predictions of $\mathcal{B}\left(B_{s}^{0} \rightarrow D_{s 2}^{-} \tau^{+} \nu_{\tau}\right)$ in Ref. [77] are smaller than ours.

Until now, the $\mathrm{SU}(3)$ flavor symmetry predictions of the three-body semileptonic $B \rightarrow D_{J} \ell^{+} \nu_{\ell}$ decays are quite coincident with their experimental data within $2 \sigma$ errors. The $\mathrm{SU}(3)$ flavor breaking effects mainly come from different masses of $u, d$, and $s$ quarks. Since $m_{u, d}$ are much smaller than $m_{s}$, the $\mathrm{SU}(3)$ breaking effects due to a non-zero $m_{s}$ dominate the $\mathrm{SU}(3)$ breaking effects [50]. If considering the $\mathrm{SU}(3)$ flavor breaking effects due to a non-zero $m_{s}$, the nonperturbative coefficients of the $B_{s}^{0} \rightarrow D_{s}^{-} / D_{s}^{*-} / D_{s 0}^{-} / D_{s 2}^{*-} \ell^{+} \nu_{\ell}$ decays are different from those of the $B^{+} \rightarrow \bar{D}^{0} / \bar{D}^{* 0} / \bar{D}_{0}^{0} / \bar{D}_{2}^{* 0} \ell^{+} \nu_{\ell}$ and $B^{0} \rightarrow D^{-} / D^{*-} / D_{0}^{-} / D_{2}^{*-} \ell^{+} \nu_{\ell}$ decays. As given in Tab. IV, decays $B_{s}^{0} \rightarrow D_{s}^{-} \mu^{+} \nu_{\mu}$ and $B_{s}^{0} \rightarrow D_{s}^{*-} \mu^{+} \nu_{\mu}$ have been measured, so one can estimate the $\mathrm{SU}(3)$ flavor breaking effects due to a nonzero $m_{s}$ in the $B \rightarrow D / D^{*} \ell^{+} \nu_{\ell}$ decays. Comparing our $\mathrm{SU}(3)$ flavor symmetry predictions and their experimental measurements of $B_{s}^{0} \rightarrow D_{s}^{-} / D_{s}^{*-} \mu^{+} \nu_{\mu}$ decays within $2 \sigma$ errors, one can find the $\mathrm{SU}(3)$ breaking contributions to $\mathcal{B}\left(B_{s}^{0} \rightarrow D_{s}^{-} \ell^{+} \nu_{\ell}\right)$ and $\mathcal{B}\left(B_{s}^{0} \rightarrow D_{s}^{*-} \ell^{+} \nu_{\ell}\right)$ should be less than roughly $23 \%$ and $20 \%$ of their experimental central values, respectively. After the $B_{s}^{0} \rightarrow D_{s 0}^{-} / D_{s 2}^{*-} \ell^{+} \nu_{\ell}$ decays are measured, one can estimate the $\mathrm{SU}(3)$ flavor breaking effects in the $B \rightarrow D_{0} / D_{2}^{*} \ell^{+} \nu_{\ell}$ decays.

## B. Non-leptonic two-body $D_{J} \rightarrow D P$ decays

Non-leptonic two-body $D_{J} \rightarrow D P$ decays via strong or electromagnetic interaction are presented in this section. Due to parity conservation, only $D_{J}=D_{0} / D^{*} / D_{2}^{*}$ resonances are considered for the $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays [78]. In terms of the $\mathrm{SU}(3)$ flavor symmetry, the decay amplitudes of the strong or electromagnetic $D_{J} \rightarrow D P$ decays can be parameterized as

$$
\begin{equation*}
A\left(D_{J} \rightarrow D P\right)=a_{01}^{D_{J}}\left(D_{J}\right)_{i} P_{j}^{i} D^{j}+a_{02}^{D_{J}}\left(D_{J}\right)_{i} D^{i} P_{j}^{j} \tag{39}
\end{equation*}
$$

where $a_{01,02}^{D_{J}}$ are the nonperturbative coefficients, and all $D_{J}$ are two-quark state. $a_{02}^{D_{J}}$ are OZI suppressed and it will be ignored in later numerical analysis. The decay amplitudes for each $D_{2}^{*} \rightarrow D P$ decay are summarized in Tab. VI. The decay amplitudes for $D^{*} / D_{0} \rightarrow D P$ can be obtained by replacing $a_{01,02}^{D_{2}^{*}}$ listed in Tab. VI with $a_{01,02}^{D^{*}, D_{0}}$ only if their phase spaces are allowed.

Then the branching ratios of the $D_{J} \rightarrow D P$ decays can be written as [79]

$$
\begin{align*}
\mathcal{B}\left(D_{0} \rightarrow D P\right) & =\frac{\tau_{D_{0}} p_{c}\left(m_{D_{0}}, m_{D}, m_{P}\right)}{8 \pi m_{D_{0}}^{2}}\left|A\left(D_{0} \rightarrow D P\right)\right|^{2}  \tag{40}\\
\mathcal{B}\left(D^{*} \rightarrow D P\right) & =\frac{\tau_{D^{*}} p_{c}^{3}\left(m_{D^{*}}, m_{D}, m_{P}\right)}{6 \pi m_{D^{*}}^{2}}\left|A\left(D^{*} \rightarrow D P\right)\right|^{2}  \tag{41}\\
\mathcal{B}\left(D_{2}^{*} \rightarrow D P\right) & =\frac{\tau_{D_{2}^{*}} p_{c}^{5}\left(m_{D_{2}^{*}}, m_{D}, m_{P}\right)}{60 \pi m_{D_{2}^{*}}^{2}}\left|A\left(D_{2}^{*} \rightarrow D P\right)\right|^{2}, \tag{42}
\end{align*}
$$

where the center of mass momentum $p_{c}\left(m_{D_{J}}, m_{D}, m_{P}\right) \equiv \frac{\sqrt{\lambda\left(m_{D_{J}}^{2}, m_{D}^{2}, m_{P}^{2}\right)}}{2 m_{D_{J}}}$.
Four decay modes of the $D^{*} \rightarrow D \pi$ decays have been measured, and the data within $2 \sigma$ errors are [1]

$$
\begin{align*}
\mathcal{B}\left(D^{* 0} \rightarrow D^{0} \pi^{0}\right) & =(64.7 \pm 1.8) \%, & & \mathcal{B}\left(D^{*+} \rightarrow D^{0} \pi^{+}\right)=(67.7 \pm 1.0) \%, \\
\mathcal{B}\left(D^{*+} \rightarrow D^{+} \pi^{0}\right) & =(30.7 \pm 1.0) \%, & & \mathcal{B}\left(D_{s}^{*+} \rightarrow D_{s}^{+} \pi^{0}\right)=(5.8 \pm 1.4) \% \tag{43}
\end{align*}
$$

Isospin violating decays $D_{s}^{*+} \rightarrow D_{s}^{+} \pi^{0}$ and later $D_{s 0}^{0} \rightarrow D_{s}^{0} \pi^{0}$, which might decay via $\eta-\pi^{0}$ mixing [80], are not considered in this work. The experimental data of $\mathcal{B}\left(D^{* 0} \rightarrow D^{0} \pi^{0}\right)$ and $\mathcal{B}\left(D^{*+} \rightarrow D^{0} \pi^{+}, D^{+} \pi^{0}\right)$ will be used to obtain $\mathcal{B}\left(B \rightarrow D \pi \ell \nu_{\ell}\right)$ with the $D^{*}$ resonances.

In the $D_{0} \rightarrow D P$ decays, only $D_{0} \rightarrow D \pi$ decays have been seen but have no data. Since $D_{0} \rightarrow D \eta, D_{0} \rightarrow D_{s} K$ and $D_{s 0} \rightarrow D K$ are not allowed by the phase spaces, we assume $\mathcal{B}\left(D_{0} \rightarrow D \pi\right)=1$ to obtain four branching ratios of the $D_{0}^{0} \rightarrow D^{0} \pi^{0}, D^{+} \pi^{-}$and $D_{0}^{+} \rightarrow D^{+} \pi^{0}, D^{0} \pi^{+}$decays. And they are

$$
\begin{align*}
\mathcal{B}\left(D_{0}^{0} \rightarrow D^{0} \pi^{0}\right) & =(33.62 \pm 0.03) \%, & & \mathcal{B}\left(D_{0}^{0} \rightarrow D^{+} \pi^{-}\right)=(66.38 \pm 0.03) \% \\
\mathcal{B}\left(D_{0}^{+} \rightarrow D^{+} \pi^{0}\right) & =(33.18 \pm 0.01) \%, & & \mathcal{B}\left(D_{0}^{+} \rightarrow D^{0} \pi^{+}\right)=(66.82 \pm 0.01) \% \tag{44}
\end{align*}
$$

The branching ratios of $D_{0} \rightarrow D \pi$ decays are the same as those in Eq. (44) when considering $D_{0}$ as the four quark state.

For the $D_{2}^{*} \rightarrow D P$ decays, since there is no experimental data of the branching ratios, we can not constrain $a_{01}^{D_{2}^{*}}$ directly. Nevertheless, $\frac{\mathcal{B}\left(D_{2}^{*} \rightarrow D \pi\right)}{\mathcal{B}\left(D_{2}^{*} \rightarrow D^{*} \pi\right)}=1.52 \pm 0.14$ within $2 \sigma$ errors are measured [1]. The $\mathrm{SU}(3)$ relation of the decay amplitudes of the $D_{2}^{*} \rightarrow D^{*} P$ decays are given in Ref. [66]. Using $\frac{\mathcal{B}\left(D_{2}^{*} \rightarrow D \pi\right)}{\mathcal{B}\left(D_{2}^{*} \rightarrow D^{*} \pi\right)}=1.52 \pm 0.14$ and assuming $\mathcal{B}\left(D_{2}^{* 0} \rightarrow D \pi\right)+\mathcal{B}\left(D_{2}^{* 0} \rightarrow D^{*} \pi\right) \leq 1, \mathcal{B}\left(D_{2}^{*+} \rightarrow D \pi\right)+\mathcal{B}\left(D_{2}^{*+} \rightarrow D^{*} \pi\right) \leq 1$ and $\mathcal{B}\left(D_{s 2}^{*+} \rightarrow D K\right)+\mathcal{B}\left(D_{s 2}^{*+} \rightarrow D^{*} K\right) \leq 1$,

TABLE VI: The decay amplitudes for the $D_{2}^{*} \rightarrow D P$ decays under the $\mathrm{SU}(3)$ flavor symmetry.

| Decay modes | Coupling vertexs | Decay modes | Coupling vertexs |
| :--- | :---: | :---: | :---: |
| $D_{2}^{* 0}(2460) \rightarrow D^{0} \pi^{0}$ | $a_{01}^{D_{2}^{*}} / \sqrt{2}$ | $D_{2}^{*+}(2460) \rightarrow D^{+} \pi^{0}$ | $-a_{01}^{D_{2}^{*}} / \sqrt{2}$ |
| $D_{2}^{* 0}(2460) \rightarrow D^{0} \eta$ | $a_{01}^{D_{2}^{*}}\left(\frac{\cos \theta_{P}}{\sqrt{6}}-\frac{\sin \theta_{P}}{\sqrt{3}}\right)-\sqrt{3} a_{02}^{D_{2}^{*}} \sin \theta_{P}$ | $D_{2}^{*+}(2460) \rightarrow D^{+} \eta$ | $a_{01}^{D_{2}^{*}}\left(\frac{\cos \theta_{P}}{\sqrt{6}}-\frac{\sin \theta_{P}}{\sqrt{3}}\right)-\sqrt{3} a_{02}^{D_{2}^{*}} \sin \theta_{P}$ |
| $D_{2}^{* 0}(2460) \rightarrow D^{+} \pi^{-}$ | $a_{01}^{D_{2}^{*}}$ | $D_{2}^{*+}(2460) \rightarrow D^{0} \pi^{+}$ | $a_{01}^{D_{2}^{*}}$ |

| $D_{s 2}^{*+}(2573) \rightarrow D_{s}^{+} \eta$ | $-a_{01}^{D_{2}^{*}}\left(\frac{2 \cos \theta_{P}}{\sqrt{6}}+\frac{\sin \theta_{P}}{\sqrt{3}}\right)-\sqrt{3} a_{02}^{D_{2}^{*}} \sin \theta_{P}$ |  |  |

TABLE VII: The predictions of the $D_{2}^{*} \rightarrow D P$ decays within $2 \sigma$ errors.

| Decay modes | Branching ratios $\left(\times 10^{-2}\right)$ | Decay widthes $(\mathrm{MeV})$ | Decay widthes from $[81](\mathrm{MeV})$ |
| :--- | :---: | :---: | :---: |
| $D_{2}^{* 0}(2460) \rightarrow D^{0} \pi^{0}$ | $20.18 \pm 1.77$ | $9.59 \pm 1.06$ | $4.14_{-1.57}^{+1.82}$ |
| $D_{2}^{* 0}(2460) \rightarrow D^{0} \eta$ | $0.13 \pm 0.03$ | $0.06 \pm 0.02$ | $\ldots$ |
| $D_{2}^{* 0}(2460) \rightarrow D^{+} \pi^{-}$ | $38.51 \pm 3.41$ | $18.30 \pm 2.03$ | $\ldots$ |
| $D_{2}^{* 0}(2460) \rightarrow D_{s}^{+} K^{-}$ | $\left[1.82 \times 10^{-15}, 6.56 \times 10^{-6}\right]$ | $\left[8.77 \times 10^{-14}, 3.00 \times 10^{-6}\right]$ | $\ldots .91_{-3.00}^{+3.49}$ |
| $D_{2}^{*+}(2460) \rightarrow D^{+} \pi^{0}$ | $19.40 \pm 1.63$ | $9.33 \pm 0.92$ | $\ldots$ |
| $D_{2}^{*+}(2460) \rightarrow D^{+} \eta$ | $0.11 \pm 0.04$ | $(5.45 \pm 2.15) \times 10^{-2}$ | $\ldots$ |
| $D_{2}^{*+}(2460) \rightarrow D^{0} \pi^{+}$ | $39.88 \pm 3.33$ | $19.18 \pm 1.90$ | $\ldots$ |
| $D_{2}^{*+}(2460) \rightarrow D_{s}^{+} \bar{K}^{0}$ | $\left[1.26 \times 10^{-14}, 1.80 \times 10^{-6}\right]$ | $\left[6.01 \times 10^{-13}, 8.28 \times 10^{-5}\right]$ | $\ldots$ |
| $D_{s 2}^{*+}(2573) \rightarrow D^{0} K^{+}$ | $42.32 \pm 5.20$ | $7.52 \pm 0.95$ | $\ldots$ |
| $D_{s 2}^{*+}(2573) \rightarrow D^{+} K^{0}$ | $38.12 \pm 4.72$ | $6.79 \pm 0.86$ | $\ldots .35_{-1.27}^{+1.48}$ |
| $D_{s 2}^{*+}(2573) \rightarrow D_{s}^{+} \eta$ | $0.58 \pm 0.19$ | $(10.23 \pm 3.43) \times 10^{-2}$ | $3.04_{-1.15}^{+1.34}$ |

one can constrain the nonperturbative coefficients $a_{01}^{D_{2}^{*}}$, and we obtain that $\left|a_{01}^{D_{2}^{*}}\right|=25.14 \pm 1.47$. Then the branching ratios of the $D_{2}^{*} \rightarrow D P$ decays can be predicted, which are summarized in the second column of Tab. VII. In addition, their decay width predictions and previous width predictions are also given in the forth and fifth columns of Tab. VII, respectively. Our width predictions are about 1 time larger than ones in Ref. [81].

## C. Numerical results of the resonant $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays

In terms of $\mathcal{B}\left(B \rightarrow D_{J} \ell^{+} \nu_{\ell}\right)$ given in Tabs. V-IV and $\mathcal{B}\left(D_{J} \rightarrow D P\right)$ given in Eqs. (43-44) and Tab. VII, after considering the further experimental bounds of the resonant $B \rightarrow D \pi \ell^{+} \nu_{\ell}$ decays given in Eqs. (2-3) and (5-6), one can obtain the branching ratio predictions of the resonant $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays, and they are listed in the third, forth and fifth columns of Tab. II for the $D^{*}, D_{0}$ and $D_{(s) 2}^{*}$ resonances, respectively. Corresponding experimental data
with $2 \sigma$ errors are also listed in Tab. II for the convenience of comparison. Note that, since the vector resonances are also considered in this work, $\mathcal{B}\left(B^{+} \rightarrow D^{-} \pi^{+} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{T}$ and $\mathcal{B}\left(B^{0} \rightarrow D^{0} \pi^{-} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{T}$ in Eq. (1) and Eq. (4) are not used for our results. Many resonant branching ratios are predicted for the first time.

One can see that the the vector meson $D^{*}$ resonances give the dominant contributions in the $B^{+} \rightarrow \bar{D}^{0} \pi^{0} \ell^{+} \nu_{\ell}$, $B^{0} \rightarrow \bar{D}^{0} \pi^{-} \ell^{+} \nu_{\ell}$ and $B^{0} \rightarrow D^{-} \pi^{0} \ell^{+} \nu_{\ell}$ decays, largely because of its proximity to the $D \pi$ threshold. Please note that decay amplitude of the $B^{+} \rightarrow D^{-} \pi^{+} \ell^{+} \nu_{\ell}$ decays is larger than ones of the $B^{+} \rightarrow D^{0} \pi^{0} \ell^{+} \nu_{\ell}$ decays by factor $\sqrt{2}$, nevertheless, the latter branching ratios are much larger than the former ones, since the most dominant resonance $D^{* 0}$ cannot decay into $D^{-} \pi^{+}$on its mass-shell [1]. In previous studies, $\mathcal{B}\left(B^{+} \rightarrow \bar{D}^{0} \pi^{0} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{D^{* 0}}=34.9 \times 10^{-3}$ [51], $\mathcal{B}\left(B^{0} \rightarrow D^{-} \pi^{0} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{D^{*-}}=16.7 \times 10^{-3}[51], \mathcal{B}\left(B^{0} \rightarrow D^{-} \pi^{0} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{D^{*-}}=14.0 \times 10^{-3}[82], \mathcal{B}\left(B^{0} \rightarrow D^{-} \pi^{0} \tau^{+} \nu_{\tau}\right)_{D^{*-}}=$ $3.53 \times 10^{-3}$ [82], after considering the error, our corresponding results are consistent with them.

As for the scalar meson $D_{0}$ resonances and the tensor meson $D_{2}^{*}$ resonances, the experimental upper limit of $\mathcal{B}\left(B^{+} \rightarrow D^{-} \pi^{+} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{D_{0}^{0}}$ gives further constraint on the $\mathcal{B}\left(B \rightarrow D \pi \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{D_{0}}$ predictions, and the experimental lower limit of $\mathcal{B}\left(B^{+} \rightarrow D^{-} \pi^{+} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{D_{2}^{* 0}}$ gives further constraint on the $\mathcal{B}\left(B \rightarrow D \pi \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{D_{2}^{*}}$ predictions. Our predictions for $\mathcal{B}\left(B^{0} \rightarrow \bar{D}^{0} \pi^{-} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{D_{0}^{-}, D_{2}^{*-}}$ are more precise than their experimental measurements. The contributions of the $D_{0}$ and $D_{2}^{*}$ resonances are in the same order of magnitude in the $B^{+} \rightarrow D^{-} \pi^{+} \ell^{\prime+} \nu_{\ell^{\prime}}$ and $B^{0} \rightarrow \bar{D}^{0} \pi^{-} \ell^{\prime+} \nu_{\ell^{\prime}}$ decays. But the contributions of the $D_{0}$ resonances are larger than ones of the $D_{2}^{*}$ resonances in the $B^{+} \rightarrow \bar{D}^{0} \pi^{0} \ell^{+} \nu_{\ell}$, $B^{0} \rightarrow D^{-} \pi^{0} \ell^{+} \nu_{\ell}, B^{+} \rightarrow D^{-} \pi^{+} \tau^{+} \nu_{\tau}$ and $B^{0} \rightarrow \bar{D}^{0} \pi^{-} \tau^{+} \nu_{\tau}$ decays.

The Belle II experiment has reported the branching ratios of the $B \rightarrow D \eta \ell^{\prime+} \nu_{\ell^{\prime}}$ decays with quite large errors, $\mathcal{B}\left(B^{0} \rightarrow D^{-} \eta \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{T}=(4.0 \pm 4.0) \times 10^{-3}$ and $\mathcal{B}\left(B^{+} \rightarrow D^{0} \eta \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{T}=(4.0 \pm 4.0) \times 10^{-3}$ [74], which are not used for our predictions. From our predictions, one can see that the non-resonant branching ratios are dominant in the $B \rightarrow D \eta \ell^{\prime+} \nu_{\ell^{\prime}}$ decays. And our predictions of $\mathcal{B}\left(B \rightarrow D \eta \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}$ lie in the range of experimental data with $1 \sigma$ error.

In addition, the interference terms between the non-resonant, the vector resonant, the scalar resonant and the tensor resonant contributions exist, and they might not be ignored if more than one kind of contributions are important in the decays, and they will be studied in our succeeding work.

All current experimental data of $\mathcal{B}\left(B \rightarrow D P \ell^{+} \nu_{\ell}\right)$ can be explained by the $\mathrm{SU}(3)$ flavor symmetry approach. For the $\mathrm{SU}(3)$ flavor breaking effects in the $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays, which are in the similar situation to the $B \rightarrow D^{*} P \ell^{+} \nu_{\ell}$ decays. The $\mathrm{SU}(3)$ flavor breaking effects due to a nonzero $s$ quark mass dominate the $\mathrm{SU}(3)$ breaking effects. As given in Tab. II, the dominate $\mathrm{SU}(3)$ flavor breaking effects might appear in the non-resonant and the charmed tensor resonant $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays. Nevertheless, there is only the data for $\mathcal{B}\left(B_{u, d} \rightarrow D \pi \ell^{+} \nu_{\ell}\right)_{D_{2}^{*}}$, and there is not any data for $\mathcal{B}\left(B_{s} \rightarrow D K \ell^{+} \nu_{\ell}\right)_{D_{s 2}^{*}}$. Or there is only the data of $\mathcal{B}\left(B^{+} \rightarrow D_{s}^{-} K^{+} \ell^{+} \nu_{\ell}\right)_{N}$, and there is no any data of $\mathcal{B}\left(B_{u, d, s} \rightarrow D K \ell^{+} \nu_{\ell}\right)_{N}$. Therefore, we can not directly judge how large the possible $\mathrm{SU}(3)$ breaking effects are in the $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays.

Although the widths of all resonances are narrow, following Refs. [51, 53], the width effects of $D^{*}$ mesons are analyzed. After considering the width effects of $D^{*}$ mesons, the decay branching ratios of $B \rightarrow D \pi \ell^{+} \nu_{\ell}$ are [51, 52]

$$
\begin{equation*}
\mathcal{B}\left(B \rightarrow D^{*} \pi \ell^{+} \nu_{\ell}\right)_{D^{*}}=\frac{1}{\pi} \int_{\left(m_{D^{*}}-n \Gamma_{D^{*}}\right)^{2}}^{\left(m_{\left.D^{*}+n \Gamma_{D^{*}}\right)^{2}}\right.} d t_{V} \int_{m_{\ell}^{2}}^{\left(m_{B}-\sqrt{t_{V}}\right)^{2}} d q^{2} \frac{\sqrt{t_{V}} d \mathcal{B}\left(B \rightarrow D^{*}(\lambda) \ell^{+} \nu_{\ell}, t_{V}\right) / d q^{2} \mathcal{B}\left(D^{*}(\lambda) \rightarrow D \pi, t_{V}\right) \Gamma_{D^{*}}}{\left(t_{V}-m_{D^{*}}^{2}\right)^{2}+m_{D^{*}}^{2} \Gamma_{D^{*}}^{2}}, \tag{45}
\end{equation*}
$$

where $d \mathcal{B}\left(B \rightarrow D^{*}(\lambda) \ell^{+} \nu_{\ell}, t_{V}\right) / d q^{2}$ and $\mathcal{B}\left(D^{*}(\lambda) \rightarrow D \pi, t_{V}\right)$ are obtained from to Eq. (35) and Eq. (41) by replacing $m_{D^{*}} \rightarrow \sqrt{t_{V}}$, respectively. There are two nonperturbative coefficients $V^{B D^{*}}(0)$ in $d \mathcal{B}\left(B \rightarrow D^{*}(\lambda) \ell^{+} \nu_{\ell}, t_{V}\right) / d q^{2}$ and $a_{01}^{D^{*}}$ in $\mathcal{B}\left(D^{*}(\lambda) \rightarrow D \pi, t_{V}\right) . V^{B D^{*}}(0)=0.65 \pm 0.05$ from the data of $\mathcal{B}\left(B \rightarrow D^{*} \ell^{+} \nu_{\ell}\right)$ listed in Tab. IV, and $a_{01}^{D^{*}}=8.42 \pm 0.38$ from the data of $\mathcal{B}\left(D^{*+} \rightarrow D \pi\right)$ given in Eq. (43). $\Gamma_{D^{* 0}}=(56.00 \pm 5.74) \mathrm{KeV}$, which is obtained
via the experimental data of $\mathcal{B}\left(D^{* 0} \rightarrow D^{0} \pi^{0}\right)$ in Eq. (43) and the $\mathrm{SU}(3)$ flavor symmetry in $D^{*} \rightarrow D \pi$. Following Refs. [51], choosing $n=3$, the results of $\mathcal{B}\left(B \rightarrow D \pi \ell^{+} \nu_{\ell}\right)_{D^{*}}$ are obtained, and they are listed in Tab. by denoting $\dagger$. One can see that the results obtained by considering the $D^{*}$ width effects are slightly smaller than ones obtained by the narrow width approximation.

## IV. Summary

The semileptonic $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays with the non-resonances, the vector resonances, the scalar resonances and the tensor resonances have been investigated by using the $\mathrm{SU}(3)$ flavor symmetry based on the relevant experimental data. The amplitude relations of the non-resonant $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays, the semileptonic $B \rightarrow D / D^{*} / D_{0} / D_{2}^{*} \ell^{+} \nu_{\ell}$ decays and the non-leptonic $D^{*} / D_{0} / D_{2}^{*} \rightarrow D P$ decays have been obtained, and then the resonant branching ratios have been obtained by the narrow width approximation after considering the resonant experimental data of the $B \rightarrow D P \ell^{\prime+} \nu_{\ell^{\prime}}$ decays. Our main results can be summarized as follows.

For the non-resonant $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays, the central values of $\mathcal{B}\left(B^{+} \rightarrow D^{-} \pi^{+} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}, \mathcal{B}\left(B^{+} \rightarrow \bar{D}^{0} \pi^{0} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}$, $\mathcal{B}\left(B^{+} \rightarrow \bar{D}^{0} \eta \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}, \mathcal{B}\left(B^{0} \rightarrow \bar{D}^{0} \pi^{-} \ell^{\prime+} \nu_{\ell^{\prime}} \mathcal{B}\left(B^{0} \rightarrow D_{s}^{-} K^{0} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}, \mathcal{B}\left(B^{0} \rightarrow D^{-} \pi^{0} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}, \mathcal{B}\left(B^{0} \rightarrow D^{-} \eta \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}\right.$, $\mathcal{B}\left(B_{s}^{0} \rightarrow \bar{D}^{0} K^{-} \ell^{\prime+} \nu_{\ell^{\prime}} \mathcal{B}\left(B_{s}^{0} \rightarrow D^{-} \bar{K}^{0} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}\right.$ and $\mathcal{B}\left(B_{s}^{0} \rightarrow D_{s}^{-} \eta \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{N}$ are on the orders of $10^{-4}$, which could be measured by the LHCb and Belle II experiments. Other non-resonant decay branching ratios of $B^{+} \rightarrow \bar{D}^{0} \eta^{\prime} \ell^{\prime+} \nu_{\ell^{\prime}}$, $B^{0} \rightarrow D^{-} \eta^{\prime} \ell^{\prime+} \nu_{\ell^{\prime}}, B_{s}^{0} \rightarrow D_{s}^{-} \eta^{\prime} \ell^{\prime+} \nu_{\ell^{\prime}}$ and all $B \rightarrow D P \tau^{+} \nu_{\tau}$ decays are strongly suppressed by the narrow phase spaces.

For the charmed vector resonant $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays, they give the dominant contributions in the $B^{+} \rightarrow \bar{D}^{0} \pi^{0} \ell^{+} \nu_{\ell}$, $B^{0} \rightarrow \bar{D}^{0} \pi^{-} \ell^{+} \nu_{\ell}$ and $B^{0} \rightarrow D^{-} \pi^{0} \ell^{+} \nu_{\ell}$ decays. Nevertheless, since the resonance $D^{* 0}$ can not decay into $D^{-} \pi^{+}$, the total branching ratios of the $B^{+} \rightarrow D^{-} \pi^{+} \ell^{+} \nu_{\ell}$ decays are much smaller than ones of the $B^{+} \rightarrow \bar{D}^{0} \pi^{0} \ell^{+} \nu_{\ell}$, $B^{0} \rightarrow \bar{D}^{0} \pi^{-} \ell^{+} \nu_{\ell}$ and $B^{0} \rightarrow D^{-} \pi^{0} \ell^{+} \nu_{\ell}$ decays.

As for the charmed scalar and tensor resonant $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays, our predictions of $\mathcal{B}\left(B^{0} \rightarrow \bar{D}^{0} \pi^{-} \ell^{\prime+} \nu_{\ell^{\prime}}\right)_{D_{0}^{-}, D_{2}^{*-}}$ are more precise than their experimental measurements. The contributions of the $D_{0}$ and $D_{2}^{*}$ resonances are in the same order of magnitude in the $B^{+} \rightarrow D^{-} \pi^{+} \ell^{\prime+} \nu_{\ell^{\prime}}$ and $B^{0} \rightarrow \bar{D}^{0} \pi^{-} \ell^{\prime+} \nu_{\ell^{\prime}}$ decays. But the contributions of the $D_{0}$ resonances are larger than ones of $D_{2}^{*}$ resonances in the $B^{+} \rightarrow \bar{D}^{0} \pi^{0} \ell^{+} \nu_{\ell}, B^{0} \rightarrow D^{-} \pi^{0} \ell^{+} \nu_{\ell}, B^{+} \rightarrow D^{-} \pi^{+} \tau^{+} \nu_{\tau}$ and $B^{0} \rightarrow \bar{D}^{0} \pi^{-} \tau^{+} \nu_{\tau}$ decays.

Although only approximate predictions can be obtained by the $\mathrm{SU}(3)$ flavor symmetry, they are still useful for understanding these decays. Until now, our predictions of the $B \rightarrow D P \ell^{+} \nu_{\ell}$ decays are quite coincident with present experimental data, and they could be tested in future experiments, such as LHCb and Belle II.
