Abstract

Recent work shows Large Language Models (LLMs) struggle to understand natural language constraints for various text generation tasks in zero- and few-shot settings. While, in the code domain, there is wide usage of constraints in code format to maintain the integrity of code written in Domain-Specific Languages¹ (DSLs), yet there has been no work evaluating LLMs with these constraints. We propose two novel tasks to assess the controllability of LLMs using hard and soft constraints represented as code across five representations. Our findings suggest that LLMs struggle to comprehend constraints in all representations irrespective of their portions in the pre-training data. While models are better at comprehending constraints in JSON, YAML and natural language representations, they struggle with constraints represented in XML and resource-rich language Python.

1 Introduction

Large language models (LLMs) have shown promising results (Brown et al., 2020) in comprehending and subsequently generating coherent text and code in zero and few-shot settings, especially for resource-rich languages. However, their practical utility depends on their ability to follow constraints at various granularity, encompassing user and system requirements. Recent work (Sun et al., 2023) shows LLMs have difficulty in understanding fine-grained hard constraints represented as a natural language in zero and few shot settings for tasks like paraphrase generation and numerical planning while performing decently well for coarse-grained constraints such as generating text on a given topic. While in the code domain, encoding use-case-specific constraints in code format

is prevalent and crucial for enterprises to maintain the integrity of the code typically written in DSLs such as JSON, YAML, and XML that are often in structured format. Such DSLs are widely adopted for data exchange and configuration of systems such as Kubernetes², and Ansible³ and there is growing interest (Nair and Modani, 2023) in employing LLMs for DSLs. Depending on the use case and system, the constraints that are often fine-grained are articulated as schemas⁴ in various code languages like JSON schema, YAML, or Python Pydantic to validate DSL code. A typical schema holds fine-grained hard and soft constraints such as data types, required and optional fields, default values, numerical constraints, etc. LLMs must be cognizant of such constraints for practical use in producing reliable code. Therefore, we aim to study and understand the controllability of LLMs when fine-grained constraints are represented in code format.

Listing 1: The JSON sample generated (highlighted in yellow) by the Granite 20B model does not adhere to the *exclusiveMaximum* and *multipleOf* constraints specified in the schema.

```
Write a JSON sample with field values as per the
JSON format schema given below.

{
  "type": "array",
  "contains": {
    "type": "number",
    "multipleOf": 2.66,
    "exclusiveMinimum": 0.08231885995435284,
    "exclusiveMaximum": 5.1100233535478
  },
  "maxContains": 10
}

JSON sample:
```
[2.66, 5.22, 8.88, 11.54, 14.2]
```

⁴we use schemas and constraints in code format interchangeably

^{*}The first two authors contribute equally.

¹<https://w.wiki/6jCH>

To evaluate the extent to which LLMs can follow these constraints in code format, we introduce two novel tasks: (i) Data as Code generation: valid sample generation factoring in constraints. (ii) DSL validation: validate code against constraints. We generate synthetic evaluation data with various combinations of constraints using combinatorial tools. This ensures no data leak and flexible control over the evaluated constraints. Our evaluation includes constraints represented as JSON schema, YAML, XML, Python Pydantic, and natural language to be generated and validated in JSON, YAML, and XML languages. We choose different input representations for schema for two reasons: (i) The selected languages are widely used across enterprises for schema representation. (ii) To study the impact of different input representations on the model’s performance under similar constraints.

To the best of our knowledge, our work is the first to study the controllability of LLMs for constraints represented as code. Our findings suggest that for Task 1, LLMs find it challenging to follow schema instructions, primarily for Python and XML schema formats. For Task 2, we observe that it is difficult for all the LLMs to validate the sample against code schema, especially when it is not adhering to that.

2 Data as Code Generation in DSL

Task description: Given the schema, the generation task (see Listing 1) aims to produce a compliant data sample in code format in a DSL of interest. We draw inspiration from use cases such as synthesizing schema-compliant data from LLMs to train and evaluate smaller-sized models (Song et al., 2020) and generating diverse sets of samples to be used in product test pipelines. Since data represented in DSL is structured, LLMs need to be schema-aware during generation.

Dataset: We synthetically prepare 602 schemas across 5 representations having combinations of hard and soft constraints. First, we prepare JSON schemas using our combinatorial tool to generate a good mix of constraints. We then convert each JSON schema to XML and YAML schemas using automated tools to ensure equivalence across representations. Further, we include Python representation using the Pydantic library as a resource-rich general-purpose language in our evaluation generated using the Gemini-1.0-pro (Team et al., 2024) model as a code translation task. We extend our

evaluation to natural language representation generated using rule-based templates over the JSON schema. We⁵ ensure equivalence of the generated schemas across languages by manually eyeballing the samples.

Evaluation metric: Each instance of schema-compliant code that LLM generates is awarded one point when these code samples are validated using a schema validator tool. We then utilize the accuracy metric over all samples to benchmark performance across various models. Along with the accuracy evaluation metric, we also report invalid data-type samples (IS%), and samples generated with the invalid root data type (RTV%). The root data type is the data type of the whole JSON sample. For example, the root data type of sample represented in listing 1 is *array*. For IS and RTV metrics, the lesser the number better the performance.

Experimental setup: We experiment with greedy decoding and beam search decoding using a beam width of 3. Both decoding techniques often perform similarly, yet greedy decoding consistently shows a slight edge; therefore, we present results using greedy decoding.

Prompts: We experiment with zero-shot and 3-shot prompting for each model. For 3-shot prompting, we identify errors from the zero-shot setting, then select and use samples similar to the most frequent errors. Using entirely different schema representations as few-shot samples does not improve model performance. Examples of prompts can be found in Appendix 1

Results: We observe that among the six schema representations studied, the natural language is best understood by the model for all output representations. For constraints in code format, JSON and YAML schema perform the best owing to their wide usage in this use case though not being one of the major languages in the pre-training data. Additionally, Python though being one of the major portions of the code pre-training data, models struggle to understand the constraints represented in Python and subsequently failing to generate valid data samples across all output languages. Similarly, models struggle to comprehend XML schema and generate in XML across all schema representations. Among the Codellama and Granite families, we observe that Granite 20B and 34B are

⁵The generated Python samples are manually validated by the paper’s authors.

Table 1: Task 1 zero shot results. SV metric denotes the percentage of perfect samples, IS denotes the percentage of invalid samples and RTV denotes the percentage of sample root data type errors. For IS and RTV, the lesser the value better the performance.

the best-performing models for all language representations except YAML where the Granite 8B model performs best. Codellama 34B model consistently gives subpar performance for code representation even when compared to the smaller Granite 8B model. Thus, we conclude that irrespective of their minor representation in code pre-training data, models perform best for JSON and natural language schema representations.

3 DSL Validation

Task description: There is a growing body of work (Chiang and Lee, 2023; Hada et al., 2024) on showing promising usage of LLMs as evaluators as an alternative to human evaluators in many tasks. While LLMs may not be deployed to validate DSL samples when schemas are in machine-readable formats, constraints can often be articulated in natural language format where automated validation is infeasible. Further, the ability to validate against the given schema throws light on LLMs’ understanding of the relation between requirements and output. Given the DSL sample to validate and the schema, the task aims to answer the validity of the provided sample against the constraints. Through this boolean question task (see Listing 2), we study the following questions: (i) How LLMs perform on varying lengths of the schemas? (ii) How well do the LLMs perform with schema in natural lan-

guage representation compared to code counterpart representations under similar constraints?

Listing 2: In the JSON sample, the values for fields *stingo* and *anisic* do not adhere to schema constraints. But the Granite 34B model gives the incorrect answer (highlighted in yellow) as *yes*.

```
Question:
Does the JSON sample {"tamil": false, "baser": null,
  "paltriness": "congue.", "anisic": 1906.34,
  "stingo": "officiis tellus. illum modi odit quas
  mattis nunc", "pigheadedness": 52.0} adhere to
all the constraints defined in JSON format
schema

{
  "type": "object",
  "properties": {
    "tamil": {"type": "boolean"},
    "baser": {"type": "null"},
    "paltriness": {},
    "anisic": {"type": "number", "multipleOf": 1
      7.02},
    "stingo": {"type": "string", "maxlen": 20},
    "pigheadedness": {"type": "number",
      "exclusiveMinimum": 27.65410407394338,
      "maximum": 93.85523810367313
    }
  },
  "additionalProperties": false,
  "required": []
}

Respond to yes or no.

Answer:
```
yes
```

```

Dataset: For each of the 602 schemas across 5 representations as described in Section 2, we

Table 2: Task 2 zero shot results. Task 2 is a binary classification task hence we measure the performance using Macro-F1 score and Accuracy.

generate 3 data samples across JSON, XML, and YAML languages. First, these data samples are synthetically generated by parsing through the JSON schema by randomly pruning and selecting constraints, resulting in data samples of different lengths and constraints. We then convert the generated JSON data samples to equivalent YAML and XML formats. The Task-2 dataset consists of 3076 instances with 45% of *no* and 55% *yes* instances.

Evaluation metric: Since it is a boolean question answering task, we use Macro average F1 score and Accuracy as evaluation metrics.

Experimental setup: The Decoding strategy used here is similar to the generation task as specified in section 2.

Prompts: The goal of this task is to answer with either *yes* or *no*. We experiment with zero-shot and few-shot prompting. In the few shot prompting we provide two examples where one example has *yes* as the answer and the other has *no* as the answer.

Results: Although natural language representation performs best for the generation task, it lowers the performance of higher parameter models like Granite 34B and codellama 34B for validation task. JSON representation works best for all three output languages for validation and Python and XML formats are most difficult to understand for all the models. Among the evaluated models,

34B models give the best performance for validation. Most of the other models give an accuracy of around 0.5 which could be a random choice of model considering there are two options *yes* or *no*. Surprisingly the Granite 20B model which performs best for the generation task, underperforms other models in most cases. We observe significant improvement in small 8B parameter models especially the llama3-8B model with natural language representation suggesting a heavy presence of natural language instances in their pre-training data. Finally, we observe that the Granite and llama family models give a similar performance for validation tasks, unlike code generation. Generating *yes* or *no* options with random probability and subpar performance of the models compared to random probability baseline for non-JSON representation suggest a large scope of improvement for this task.

4 Related Work

Generation: There is extensive work (Chen et al., 2021; Muennighoff et al., 2024; Austin et al., 2021; Lai et al., 2022; Cassano et al., 2022; Hendrycks et al., 2021; Yin et al., 2018) on evaluating code capabilities of LLMs for various code tasks such as code completion, translation, fixing, etc. These code benchmarks are often language-scoped, where resource-rich languages such as Python are widely evaluated. Despite there being work (Cassano et al., 2022) on multi-lingual code, there is scant atten-

tion to resource-poor languages such as DSLs, including YAML and JSON, though having crucial importance.

Validation: Given the limited availability of benchmarks for low resource languages, coupled with the promising performance demonstrated by LLMs (Wei et al., 2023; Sanh et al., 2022) on unseen tasks when provided with task-specific instructions, there is an emerging body of work (Hada et al., 2024; Chiang and Lee, 2023) in studying LLMs as evaluators for low-resource languages. However, attributing to prompt sensitivity, bias, and hallucinations, LLMs are not yet available as a drop-in replacement for human evaluators. There is some interest (Lian et al., 2024) in using LLMs as evaluators for low-resource languages such as DSLs, however limited to XML and INI languages.

Controllability of LLMs: Though LLMs are controllable on coarse-grained natural language constraints, such as generating text coherent with the provided topic or sentiment, they struggle (Sun et al., 2023) with fine-grained constraints such as end the text with the given word or generate text within the given word count. Code schemas often encompass fine-grained constraints, and to the best of our knowledge, we are the first to study the controllability of LLMs for constraints represented as code.

5 Conclusion

We introduce two novel tasks to test the controllability of LLMs when constraints are in code format that are profound in the use of DSLs for data exchange and configuration of systems. We evaluate LLMs over 5 schema representations that include YAML, JSON, Python, XML, and natural language and 3 output representations that include YAML, JSON, and XML. Through both the tasks, we conclude that there is substantial scope of improvement for LLMs to comprehend constraints in code format to subsequently generate compliant sample or validate the given sample. Further, findings show that LLMs do not exhibit a direct correlation with the size of the language in the pre-training data used. Since LLMs struggled to comprehend constraints represented in resource-rich language Python rather showed better performance for JSON and natural language that are minor portions of the code pre-training data. We hope that our work provides some guidance on when to employ LLMs

given the languages of interest and as well research in the direction to improve LLMs towards better controllability over code constraints.

A Appendix

A.1 Prompts

This section defines the prompts which are used for models. We report different prompts for every

model tried here and report the best-performing prompt results. Generally, the model consists of a System Prompt followed by a prompt template specific to the model.

A.1.1 Common prompt

For zero shot inference, we use a common prompt as it is for all the models irrespective of the model's prompt format and we observe best results for Task-1 with this prompt. The prompt is as follows.

Listing 3: common prompt

```
Write an {input_representation} sample with field
values as per the {output_representation}
format schema given below.

{schema}

{output_representation} sample:
```

```

### A.1.2 Granite model family

The granite model generally follows the question-answering format. Task-1 prompts for granite family models are as follows.

#### System prompt:

System:

You are an intelligent AI programming assistant, utilizing a Granite code language model developed by IBM. Your primary function is to assist users in code explanation, code generation and other software engineering tasks. You MUST follow these guidelines: - Your responses must be factual. Do not assume the answer is yes when you do not know, and DO NOT SHARE FALSE INFORMATION.  
- You should give concise answers. You should follow the instruction and provide the answer in the specified format and DO NOT SHARE FALSE INFORMATION.

#### Prompt 2:

Listing 4: QA-prompt-1

```
{System prompt}

Question:
Write an {input_representation} sample with field
values as per the {input_representation} format
schema given below.

{schema}

Answer:
```

```

Prompt 3:

Listing 5: QA-prompt-2

```
{System prompt}

Question:
Write an {input_representation} sample with field
values as per the {output_representation}
format schema given below. Please wrap your
code
answer using ```

{schema}

Answer:
```

```

{output\_representation} and {input\_representation} are the variables where {input\_representation} take the values JSON, YAML, XML, Python, and natural language. {output\_representation} takes the values JSON, YAML, and XML.

### A.1.3 Llama family

For codellama 34B model we wrap the common prompt in [INST] and [/INST] tags. For the llama3-8B model, we use the System prompt along with user tags<sup>6</sup>.

**System prompt:** You are a helpful, respectful, and honest assistant. Always answer as helpfully as possible, while being safe. Your answers should not include any harmful, unethical, racist, sexist, toxic, dangerous, or illegal content. Please ensure that your responses are socially unbiased and positive. If a question does not make any sense or is not factually coherent, explain why instead of answering something not correct. If you don't know the answer to a question, please don't share false information.

Other than this, similar to the granite family we try Question answering format and instruction to wrap the output in quotes ("").
