

# reBEN: Refined BigEarthNet Dataset for Remote Sensing Image Analysis

Kai Norman Clasen, *Member, IEEE*, Leonard Hackel, *Graduate Student Member, IEEE*, Tom Burgert, Gencer Sumbul, *Member, IEEE*, Begüm Demir, *Senior Member, IEEE*, Volker Markl

**Abstract**—This paper presents refined BigEarthNet (reBEN) that is a large-scale, multi-modal remote sensing dataset constructed to support deep learning (DL) studies for remote sensing image analysis. The reBEN dataset consists of 549,488 pairs of Sentinel-1 and Sentinel-2 image patches. To construct reBEN, we initially consider the Sentinel-1 and Sentinel-2 tiles used to construct the BigEarthNet dataset and then divide them into patches of size 1200 m × 1200 m. We apply atmospheric correction to the Sentinel-2 patches using the latest version of the sen2cor tool, resulting in higher-quality patches compared to those present in BigEarthNet. Each patch is then associated with a pixel-level reference map and scene-level multi-labels. This makes reBEN suitable for pixel- and scene-based learning tasks. The labels are derived from the most recent CORINE Land Cover (CLC) map of 2018 by utilizing the 19-class nomenclature as in BigEarthNet. The use of the most recent CLC map results in overcoming the label noise present in BigEarthNet. Furthermore, we introduce a new geographical-based split assignment algorithm that significantly reduces the spatial correlation among the train, validation, and test sets with respect to those present in BigEarthNet. This increases the reliability of the evaluation of DL models. To minimize the DL model training time, we introduce a software tool (called as richdl) that converts the reBEN dataset into a DL-optimized data format. In our experiments, we show the potential of reBEN for multi-modal multi-label image classification problems by considering several state-of-the-art DL models. The pre-trained model weights, associated code, and complete dataset are available at <https://bigearth.net>.

**Index Terms**—Multi-modal learning, multi-label image classification, deep learning, remote sensing.

## I. INTRODUCTION

THE rapid evolution of satellite systems results in a significant growth of remote sensing (RS) image archives. For an accurate analysis of the vast amount of data available, it is necessary to define automatic methods. To this end, developing deep learning (DL) based methods is a growing research interest in the RS community [1]. To support the development and assessment of such methods, several large-scale benchmark datasets have been presented in RS [2]–[4]. A comprehensive list of RS benchmark datasets is given in

K. Clasen, L. Hackel, T. Burgert, B. Demir, and V. Markl are with the Berlin Institute for the Foundations of Learning and Data (BI-FOLD) and Technische Universität Berlin, 10623 Berlin, Germany (emails: k.clasen@tu-berlin.de, l.hackel@tu-berlin.de, t.burgert@tu-berlin.de, demir@tu-berlin.de, volker.markl@tu-berlin.de). G. Sumbul is with the École Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland (email: gencer.sumbul@epfl.ch). This work is supported by the European Research Council (ERC) through the ERC-2017-STG BigEarth Project under Grant 759764 and by the European Space Agency through the DA4DTE (Demonstrator precursor Digital Assistant interface for Digital Twin Earth) project.

[5]. Among the existing datasets, one of the widely used datasets is BigEarthNet[2], [3] (also known as BigEarthNet-MM). BigEarthNet is a large-scale multi-modal and multi-label benchmark dataset presented in the framework of remote sensing image classification and retrieval problems. It consists of Sentinel-1 and Sentinel-2 image patches covering 10 European countries. With its release, it has paved the way for the design and development of different benchmark datasets in RS. For instance, in [6] the ben-ge dataset is constructed by adding geographical (e.g., climate-zone and topographic data) and environmental (e.g., weather and seasonal information) data to the BigEarthNet patches. As another example, the RSVQAxBEN dataset comprises BigEarthNet patches, as well as semantic content-related questions and answers formulated in natural language, which is presented in [7] for visual question answering (VQA) problems.

Although BigEarthNet has been proven as an effective dataset in RS, we have recently identified some issues:

- 1) Atmospheric correction tool updates: The Sentinel-2 tiles of the BigEarthNet dataset have been pre-processed with the atmospheric correction tool sen2cor [8] version 2.5.5 [9] from the European Space Agency (ESA), as it was the recommended version during the dataset creation. Since then, updates to the sen2cor pre-processor have improved the output of processed Sentinel-2 tiles. Due to the different outputs of the atmospheric correction tools, DL models trained on BigEarthNet may not perform as well on tiles pre-processed with recent versions [10].
- 2) Land use land cover (LULC) label noise: During the construction of the BigEarthNet dataset, the land use and land cover classes were derived from the preliminary CORINE Land Cover (CLC) map of 2018 (CLC2018) [11]. However, since then the CLC2018 map has received several updates that address wrong and missing label annotations (label noise). Thus, the BigEarthNet dataset contains label noise that negatively affects the training and evaluation of DL models [12]. Furthermore, the BigEarthNet dataset does not include pixel-level reference maps, making it unsuitable for pixel-based learning tasks.
- 3) Training, validation, and test split correlation: The recommended split in the BigEarthNet dataset has a high spatial correlation among the training, validation and test sets, making it difficult to evaluate results reliably.
- 4) Limited software tools for efficient and effective DL model training: Loading and processing the BigEarthNet

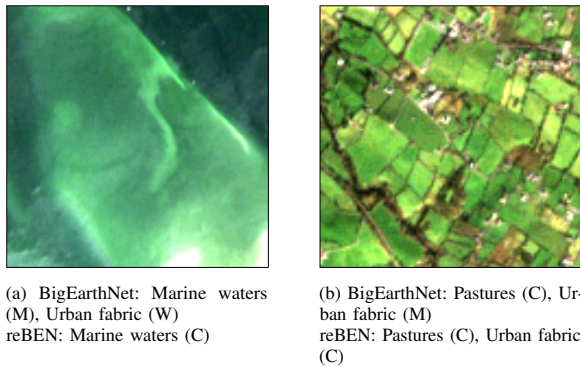

Fig. 1. Two example patches with the associated multi-labels from the BigEarthNet and reBEN datasets, where the correct labels are indicated by (C), wrong labels by (W) and missing labels by (M).

image data takes a considerable amount of time, which is especially noticeable when training DL models.

- 5) Lack of recent pre-trained models: While pre-trained DL models were made available with the release of the BigEarthNet dataset, several DL architecture advancements have been developed in the meantime. Such state-of-the-art models pre-trained on BigEarthNet are currently not available.

All of these issues affect the development and evaluation of BigEarthNet-based datasets and DL models using these datasets. To overcome this problem, we introduce the reBEN dataset<sup>1</sup> that addresses the above-mentioned issues, leading to more reliable and interpretable research in RS image analysis compared to the BigEarthNet dataset.

## II. REBEN DATASET

This section provides a detailed description of the reBEN dataset.

### A. reBEN patch generation and labeling procedure

To generate reBEN patches, we initially downloaded the same 125 Sentinel-2 level-1C tiles (which are associated to less than 1% cloud cover acquired between June 2017 and May 2018) considered in BigEarthNet from the new Copernicus Data Space Ecosystem (CDSE). These tiles were selected to represent each geographical location in different seasons. To obtain the atmospherically corrected and ortho-rectified bottom-of-atmosphere reflectance data product Sentinel-2 level-2A, we utilized the most recent version of the atmospheric correction tool `sen2cor` (version 2.11) [10].

After obtaining the 125 Sentinel-2 level-2A tiles, the metadata embedded within each level-2A tile was inspected. The metadata contains quality indicator fields (e.g., for radiometric and geometric values) that inform the user about potential issues related to the respective tile. For a detailed description of all quality indicator values and what checks are associated with them, the reader is referred to the official Sentinel-2 product specification document [13]. Among the 125 tiles, 6 tiles fail radiometric and geometric quality indicator checks. We

Fig. 2. An example of pixel-level reference maps associated to different amounts of unlabeled pixels depicted in white: (a) shows a reference map that has a small number of unlabeled pixels whose associated patch is not removed; and (b) shows a reference map that has less than 75% of pixels annotated, thus its associated patch is excluded from the reBEN dataset.

have decided not to include these tiles to ensure high-quality Sentinel-2 data in reBEN. Then, the remaining tiles were split into patches covering a region of  $1200\text{ m} \times 1200\text{ m}$  each. Note that the resulting patches cover the exact same geographical areas as the patches in the BigEarthNet dataset. In the reBEN dataset, patches that contain pixels with invalid data are not considered, whereas those that are fully covered by seasonal snow, clouds and cloud shadows are listed in a separate file but kept, as in the case of BigEarthNet. The Sentinel-1 patches from BigEarthNet are added to reBEN to produce the complete multi-modal reBEN.

After constructing the patches, each patch is associated with a pixel-level reference map obtained by overlaying the considered patch with the polygons from the most recent CLC2018 map (v2020\_20u1) [14]. This allows the use of the reBEN dataset for pixel-based learning tasks. Additionally, multi-labels are extracted from the pixel-level reference maps to exploit reBEN for scene-based learning tasks (e.g., multi-label scene classification, image retrieval). Due to the use of the most recent CLC2018 [14] label map, the LULC label noise problem present in BigEarthNet is addressed (see Fig. 1). From Fig. 1a, one can see that a patch with the label “Marine waters” was mislabeled as “Urban fabric” in BigEarthNet, while it is correctly labeled in the reBEN dataset. Fig. 1b shows a patch where BigEarthNet only contains the “Pastures” label, however, it is missing the “Urban fabric” label. In reBEN, the patch is correctly annotated with both labels. Note that the LULC class labels of reBEN are defined based on the 19-class nomenclature as in [3].

Some of the reBEN patches are either only partially labeled or completely unlabeled. This is due to two main reasons. One reason is that the most recent CLC2018 map [14] covers a smaller geographical area than the one used in BigEarthNet. The other reason is due to the use of the 19-class nomenclature. We have decided to exclude the patches with no labels from the reBEN dataset. However, removing all patches that are not fully annotated by class labels would be overly stringent. Therefore, we only remove a patch if less than 75% of its pixels are annotated. The value of 75% was identified based on a validation procedure that provides a balanced tradeoff between potentially associated label noise due to missing label information and excluding an excessive number of patches.

TABLE I

THE NUMBER OF IMAGE PAIRS OF EACH LULC CLASS THAT IS NOT COVERED BY SNOW OR CLOUDS IN TRAINING, VALIDATION, AND TEST SETS FOR THE reBEN DATASET.

LCLU	Train	Validation	Test	Total
Agro-forestry areas	15,082	8157	9942	33,181
Arable land	88,236	49,737	50,052	188,025
Beaches, dunes, sands	738	426	152	1316
Broad-leaved forest	64,164	35,387	36,377	135,928
Coastal wetlands	670	610	117	1397
Complex cultivation patterns	51,034	26,486	22,078	99,598
Coniferous forest	76,344	39,554	39,043	154,941
Industrial or commercial units	6398	2726	2018	11,142
Inland waters	30,466	15,900	16,846	63,212
Inland wetlands	11,344	5056	4519	20,919
Land principally occupied by agriculture, with significant areas of natural vegetation	60,127	32,736	29,846	122,709
Marine waters	35,914	14,064	11,854	61,832
Mixed forest	78,791	42,705	44,284	165,780
Moors, heathland and sclerophyllous vegetation	6329	3806	3759	13,894
Natural grassland and sparsely vegetated areas	6984	2687	2211	11,882
Pastures	42,968	25,915	26,722	95,605
Permanent crops	15,190	8688	5710	29,588
Transitional woodland, shrub	64,198	36,429	40,523	141,150
Urban fabric	33,626	17,308	12,824	63,758

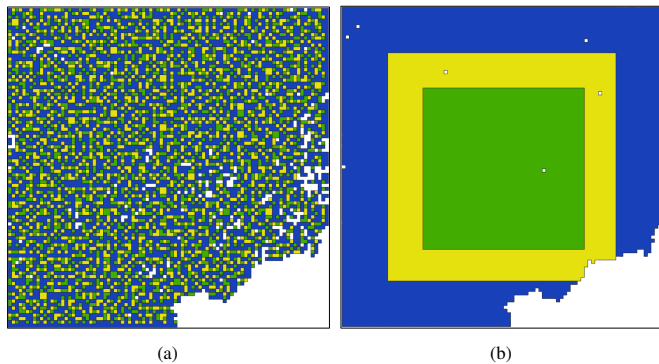

Fig. 3. Results of the BigEarthNet and reBEN split assignment algorithms on one of the 119 tiles. The patches of the training, validation and test sets are colored in blue, yellow, and green, respectively. The uncolored areas represent invalid patches. (a) shows the results obtained by the grid-based split assignment algorithm from BigEarthNet with patches from different sets within close spatial proximity to each other; and (b) shows the results obtained by the geographical-based split assignment algorithm of reBEN with larger distances between patches of different splits.

Fig. 2 shows an example of pixel-level reference maps. The map given in Fig. 2a has only a small number of unlabeled pixels. Thus, its associated patch is not excluded. However, the patch associated with the map shown in Fig. 2b is excluded as less than 75 % of the pixels are labeled. Due to the above-mentioned reasons, the total number of the remaining pairs of patches in reBEN is 549,488, which is slightly smaller than that of BigEarthNet. We would like to note that we make the code<sup>2</sup> to construct reBEN publicly available to support reproducibility. This can also allow one to easily extend the dataset to other desired geographical areas.

### B. Recommended training, validation, and test split

The training, validation, and test split in BigEarthNet is constructed by using a grid-based split assignment algorithm. Fig. 3a visualizes the spatial distribution of the sets for an

example tile. From the figure, one can observe that this algorithm results in highly correlated sets, which prevents reliable evaluation of the results.

To address this issue, we introduce a new geographical-based split assignment algorithm. Our algorithm divides the area of a tile into an inner square surrounded by an inner and outer frame as shown in Fig. 3b. We assign the patches in the outer frame to the training set, those in the inner frame to the validation set, and the remaining ones to the test set (see Fig. 3b). This results in a distinct separation among the patches of the training, validation, and test sets, while maximizing the distance between the training and test sets. It is important to note that adjacent Sentinel-2 tiles have overlapping borders. Assigning the training set to the outer frame ensures that the overlapping patches acquired within the same season are located within the same split. By this way, these overlapping patches do not implicitly skew the evaluation results. This is an important enrichment compared to the split used in BigEarthNet, where overlapping patches are assigned to separate sets.

We aim to produce a similar number of patches per set as in the BigEarthNet dataset. Given the total area of a Sentinel-2 tile, which is guaranteed to be a square with size  $s \times s$ , the width of the outer frame  $f_o$  is given by  $f_o = ((\sqrt{p+q} - \sqrt{p})/2) s$  and the width of the inner frame  $f_i$  is given by  $f_i = ((1 - \sqrt{p+q})/2) s$ , where  $p$  is defined as the ratio of the inner-most square over the total area, and  $q$  is the ratio of the area of the inner frame over the total area. To obtain a training, validation, and test sets ratio of 2:1:1 similar to BigEarthNet,  $p = q = 0.25$  are selected. Table I reports the number of patch pairs of the resulting training, validation, and test sets available for each LULC class in reBEN.

### C. Supplementary software tools

The reBEN patches are available in the same format (GeoTIFF) as in the BigEarthNet dataset. However, this format is not optimized for training and evaluating DL models. The training and evaluation time can be greatly reduced by converting the

files into a beneficial DL format that removes unnecessary metadata and stores only the image data (which is stored in such a way that high random read throughput can be achieved without requiring modifications to the underlying data). To this end, we provide a data format conversion tool (rico-hdl<sup>3</sup>) that takes the patch and stores the name of the patch as well as its data as a key-value pair in an LMDB [15] database, where the data is encoded in the DL library agnostic safetensor [16] format. Utilizing a DL library independent encoding is important to ensure that researchers can continue to use the library of their choice while benefitting from significantly faster data access. To ensure that the conversion into the optimized format remains accessible, we publish rico-hdl as a standalone, self-contained Linux binary and provide in-depth documentation about its usage.

#### D. Pre-trained models

We provide an extensive selection and comparison of state-of-the-art DL models that are: i) ResNet [17]; ii) vision transformer (ViT) [18]; iii) MLP-Mixer [19]; iv) ConvMixer [20]; v) MobileViT [21]; and vi) ConvNeXt-v2 [22].

The ResNet model is a well-known convolutional neural network (CNN) based model that utilizes skip-connections for easier training of deep neural networks [17]. The ViT model is the pioneering image transformer architecture in the computer vision and RS domain. The ViT model lacks an inherent inductive bias in its architectural design, allowing it to learn patterns more flexibly from the data it is trained on through the use of attention [18]. The MLP-Mixer model is based exclusively on multi-layer perceptrons (MLPs) and does not rely on convolution or attention layers [19]. The

ConvMixer architecture, inspired by the previous two models, is a purely convolutional architecture that operates on image patches [20]. The MobileViT model is notable for its speed and efficiency with a focus on a high inference throughput. MobileViT is particularly beneficial for applications with limited computational resources or those that require near real-time processing [21]. ConvNeXt-v2 is a pure CNN based model that took inspiration from recent ViT-based works. It improves upon the classic and widely popular ResNet [17] by introducing the Global Response Normalization (GRN) layer and adopting popular ideas, such as inverted bottleneck blocks and larger receptive fields. ConfigILM [23] is utilized to train the considered models. The associated code<sup>4</sup> as well as the pre-trained weights<sup>5</sup> are publicly available.

### III. EXPERIMENTAL RESULTS

In the experiments, we trained the above-mentioned models (ResNet, ViT, MLP-Mixer, ConvMixer, MobileViT, ConvNeXt) in the framework of multi-modal RS image scene classification. To this end, we considered the following model configurations: i) two ResNets with different numbers of layers (ResNet-50, ResNet-101) [17]; ii) ViT Base [18]; iii) MLP-Mixer Base [19]; iv) ConvMixer-768/32 [20]; v) MobileViT-S [21]; and vi) ConvNeXt-v2 Base [22].

In the experiments, we did not use the Sentinel-2 image bands associated with 60 m spatial resolution (bands 1 and 9). This is due to the fact that these bands are primarily utilized for cloud screening, atmospheric correction, and cirrus detection in RS applications, and do not contain a substantial amount of information for the characterization of the semantic

<sup>3</sup><https://github.com/rsim-tu-berlin/rico-hdl>

<sup>4</sup><https://git.tu-berlin.de/rsim/reben-training-scripts>

<sup>5</sup><https://huggingface.co/BIFOLD-BigEarthNetv2-0>

content of RS images [3]. The lower resolution 20 m Sentinel-2 bands were upsampled via nearest neighbour interpolation to the size of the 10 m resolution bands. To achieve multi-modal learning, we stacked the Sentinel-1 and the Sentinel-2 bands into one volume. As recommended in [3], we do not consider the patches that are covered by snow, clouds or cloud shadows. The train, validation and test sets were obtained by applying the geographical-based split assignment algorithm. All models were trained three times with different seeds for up to 100 epochs with the AdamW optimizer and a linear-warmup-cosine-annealing learning rate of  $1 \times 10^{-3}$  after 1000 warm-up steps with batch size, dropout and drop path set to 512, 0.15 and 0.15, respectively. The averaged results across the three runs are reported. All models were trained on a single H100 GPU. To evaluate the results, we employ two average precision (macro and micro averaged) metrics (denoted as  $AP^M/AP^\mu$ ), the macro and micro averaged  $F_1$  score ( $F_1^M/F_1^\mu$ ), as well as the macro and micro averaged precision scores (Precision<sup>M</sup>/Precision<sup>μ</sup>). The results of the considered models obtained when using reBEN with: i) only the Sentinel-1 images (denoted as S1); ii) only the Sentinel-2 images (denoted as S2); and iii) both S1 and S2 together (denoted as S1+S2) are shown in Table II.

By assessing the table, one can observe that the joint use of S1 and S2 improves the performance associated to each metric compared to those obtained by using either S1 or S2 only. As an example, ResNet-101 achieves an  $AP^M$  performance of 71.21 % with S1+S2 and performs 0.57 % and 8.75 % better than trained on S2 and S1, respectively. The use of S2 results in higher performance compared to S1 only. In detail, when S1 and S2 are jointly considered, the ResNet models generally lead to the highest performance. For example, in terms of  $AP^M$ , the ResNet-50 model achieves 71.36 % and is 0.15 % and 1.22 % higher than the ResNet-101 (second best) and the MobileViT-S (third best) model, respectively. The lowest performance is, in general, obtained by the Base ViT model. As an example, the use of the Base ViT model yields an  $AP^M$  of 66.09 %, which is almost 4 % lower than that obtained by ResNet-50.

#### IV. CONCLUSION AND DISCUSSION

In this paper, we have introduced refined BigEarthNet (reBEN) that significantly improves the BigEarthNet dataset by: 1) utilizing the most recent version (2.11) of the sen2cor atmospheric correction tool and removing the tiles with failing quality indicators from the dataset; 2) overcoming the LULC label noise present in BigEarthNet by utilizing the latest CLC map to derive the labels, while also making the pixel-level reference maps available; 3) proposing a new recommended split that utilizes a geographical-based split assignment algorithm to reduce the spatial correlation among the training, validation, and test sets by assigning the geographically overlapping patches of the same season only to the training set; 4) providing new software tools to efficiently train DL models; as well as 5) releasing pre-trained weights obtained by using state-of-the-art DL models.

We expect that reBEN will lead to more reliable and interpretable research results for image classification and retrieval in RS compared to the BigEarthNet dataset.
