

# RHRSegNet: Relighting High-Resolution Night-Time Semantic Segmentation

Sarah Elmahdy, Rodaina Hebishy, Ali Hamdi

MSA University

Giza, Egypt

{sarah.kamaleldeen, rodina.mohamed1,ahamdi}@msa.edu.eg

**Abstract**—Night-time semantic segmentation is a crucial task in computer vision, focusing on accurately classifying and segmenting objects in low-light conditions. Unlike daytime techniques, which often perform worse in nighttime scenes, it is essential for autonomous driving due to insufficient lighting, low illumination, dynamic lighting, shadow effects, and reduced contrast. We propose RHRSegNet, implementing a relighting model over a High-Resolution Network for semantic segmentation. RHRSegNet implements residual convolutional feature learning to handle complex lighting conditions. Our model then feeds the lightened scene feature maps into a high-resolution network for scene segmentation. The network consists of a convolutional producing feature maps with varying resolutions, achieving different levels of resolution through down-sampling and up-sampling. Large nighttime datasets are used for training and evaluation, such as NightCity, City-Scape, and Dark-Zurich datasets. Our proposed model increases the HRnet segmentation performance by 5% in low-light or nighttime images. The code is available at the following URL: <https://github.com/SarahELMAHDY03/RHRSegNet.git>.

## I. INTRODUCTION

Semantic segmentation, a fundamental task in computer vision, involves the challenging process of assigning semantic labels to each pixel in an image. This significant effort enhances scene understanding and aids in recognizing objects within the visual context. Despite notable advances in semantic segmentation for daytime conditions, addressing the complexities of low-light conditions presents an additional set of challenges. With the growth of deep learning and machine learning, many techniques for semantic segmentation have recently been proposed. These methods perform very well; however, their application to nighttime imaging has not been extensively studied. Reduced visibility and increased noise in low-light conditions often cause existing approaches to fail in maintaining accuracy. This work aims to close this gap by introducing a novel strategy for semantic segmentation during nighttime. Utilizing deep learning techniques and algorithms adapted for low-light conditions, our goal is to enhance the precision and reliability of segmentation. An increasing number of researchers have started to segment more complex images under various types of degradation, such as those captured at night or in hazy conditions. Semantic segmentation of nighttime images is the main focus of this research, as it has numerous significant applications in autonomous driving. In this paper, we propose RHRSegNet, a model for nighttime semantic segmentation, using the Night-city, Cityscape, and

Dark Zurich datasets. Previous work employed an intermediate twilight domain for gradually adapting semantic models trained in daylight scenarios to evening conditions [5]. [14], [15] later expanded this into a guided curriculum adaptation framework, leveraging the cross-time-of-day relationship of scene photographs using both stylized synthetic images and unlabeled real images. However, these progressive adaptation methods typically require training multiple semantic segmentation models, such as the three models in [14] for three distinct domains, which is highly inefficient. Moreover, their performance fails in some specific circumstances. Most existing semantic segmentation approaches are not designed for nighttime. While considerable progress has been made in semantic segmentation for daytime scenes, tackling low-light conditions presents unique challenges. This is particularly relevant in applications such as autonomous driving, where accurate scene interpretation at night is crucial for safe navigation. The primary contributions of our work are as follows: we propose RHRSegNet, which incorporates a relighting model followed by a segmentation model. The main contributions of our work are summarized as follows:

- We present RHRSegNet, a novel semantic segmentation method designed to address lighting challenges in nighttime environments, offering precise semantic information distinction in low-light conditions with minimal additional parameters.
- We improve nighttime semantic segmentation by transferring knowledge between the Cityscape dataset and Dark Zurich dataset, enhancing object segmentation in low-light situations by effectively transferring knowledge between domains.
- We experimented with RHRSegNet without domain adaptation on NightCity, achieving high performance.

The rest of the paper is structured as follows. Section 2 introduces the related work. Section 3 presents the proposed research methodology. The datasets used and experimental results are explained in Sections 4 and 5, respectively.

## II. RELATED WORK

### A. Nighttime Semantic Segmentation

Semantic segmentation at night has seen advancements through various methods. [5] introduced the concept of using an intermediate twilight domain to gradually transform

semantic models trained in daylight scenarios to evening situations. This approach was expanded upon by [14], [15], who developed a guided curriculum adaptation framework leveraging the cross-time-of-day relationship in scene photographs, employing both stylized synthetic images and unlabeled actual images. However, such progressive adaptation methods often necessitate training multiple semantic segmentation models for different domains, as seen in [14]. This approach can be resource-intensive and wasteful. Subsequent research [12], [13], [16] has explored the use of additional image transfer models, such as CycleGAN [25], for day-to-night or night-to-day image translation prior to training semantic segmentation models. The effectiveness of these techniques heavily relies on the performance of the pre-trained image transfer model. Recognizing the resilience of thermal radiation to changes in light, Vertens et al. [19] proposed the incorporation of thermal infrared images alongside RGB images for nighttime semantic segmentation. Additionally, domain adaptation techniques, as demonstrated in [7], have been employed for semantic segmentation of night scenes. NightLab [6] categorizes items as simple or complex. A Hardness Detection Module identifies difficult categories and sends them to a segmentation module. [22] suggest employing image frequency distributions for nighttime scene analysis. However, these methods do not estimate the impact of lighting on semantics.

### B. Semantic Segmentation

Semantic segmentation aims to categorize each pixel individually. Recently, methods based on Fully Convolutional Networks (FCN) [11] paired with encoder-decoder architectures have dominated this field. Various techniques [1], [2], [23] utilize dilated convolutions to expand the receptive field, while PSPNet [24] employs a pyramid pooling module (PPM) to capture multi-scale contexts. Integrating these advancements, the DeepLab series [1]–[4] introduces atrous spatial pyramid pooling (ASPP) to incorporate contextual information. More recently, self-attention mechanisms have been extensively used to capture long-range dependencies in semantic segmentation. Additionally, several transformer-based networks, including Vision Transformer and Swin Transformer, have been used to provide stronger backbones. Moreover, ConvNeXt [10] has emerged as a competitive alternative to transformers. However, the majority of these methods are primarily focused on daytime scenes.

## III. RESEARCH METHODOLOGY

### A. Relighting Model

The relighting model simulates lighting changes using a shared-weight architecture, allowing for a robust and unified approach. The relighting model takes an input image, passes it through four convolutional layers, three residual blocks, and two transposed convolutional layers. Each layer is followed by a batch normalization layer. The relighted image is created by combining the output of the last layer with the input image. The resulting relighted image is then passed to the HRNet.

$$I_e = \text{BN1}(\text{TransConv2D}(\text{BN2}(\text{Conv2D}(I))) + I) \quad (1)$$

In this simplified equation:  $I_e$  represents the enhanced image. Conv1 and Conv2 are convolutional layers.

BN1 and BN2 are batch normalization layers.

+ denotes the skip connection, where  $I$  is added to the output of the first convolutional layer before being processed by the second convolutional layer and batch normalization, as shown in Figure 1.

### B. Learning Parameter Sharing

This research utilizes shared weights in the relighting network to optimize learning parameter utilization, improve computational and memory efficiency, generate transferable insights, and ensure consistent feature extraction. Let  $W$  represent the shared weights within the relighting network. Let  $f(x)$  represent the function of the relighting network, where  $x$  is the input image. Then, the output of the relighting network can be represented as:

$$\text{Output} = f(x; W) \quad (2)$$

Here,  $f(x; W)$  denotes the function  $f$  parameterized by the shared weights  $W$ , which generates the relighted output given the input image  $x$ . The equation explains how shared weights are used in a relighting network to adapt to different lighting conditions and input domains, enhancing computation, memory utilization, and generalization capabilities. This approach improves knowledge transfer across datasets and generalization capabilities, outperforming traditional methods in computational efficiency and result quality. It also optimizes model training and inference processes, allowing the network to quickly adjust to new lighting conditions.

### C. Semantic Segmentation Network

High-resolution representations are crucial for high-resolution problems like semantic segmentation, human pose estimation, and object detection. The High-Resolution Network (HRNet) maintains these representations by connecting high-to-low resolution convolution streams in parallel and repeatedly exchanging information across resolutions. The HRNet architecture is divided into many phases, each of which aims to incrementally improve and aggregate multi-scale characteristics for accurate semantic segmentation. Our model consists of a series of fundamental blocks, starting with an input layer, followed by convolutional layers, Batch Normalization, ReLU activation functions, residual connections, and an output layer. The model uses a hierarchical processing pipeline, which includes downsampling, convolutional operations, Batch Normalization, ReLU activation functions, and an output layer for model predictions. This model takes the relighted image and processes the input features at the original resolution, setting the model at the first stage (STAGE1). Then, by adding more branches and blocks, the subsequent stages (STAGE2, STAGE3, STAGE4) increase the network's capacity and allow it to capture features at various resolutions. The transition layer is used to bridge feature maps of different resolutions between the adjacent stages of the network. Each phase consists of high-resolution modules that combine feature maps

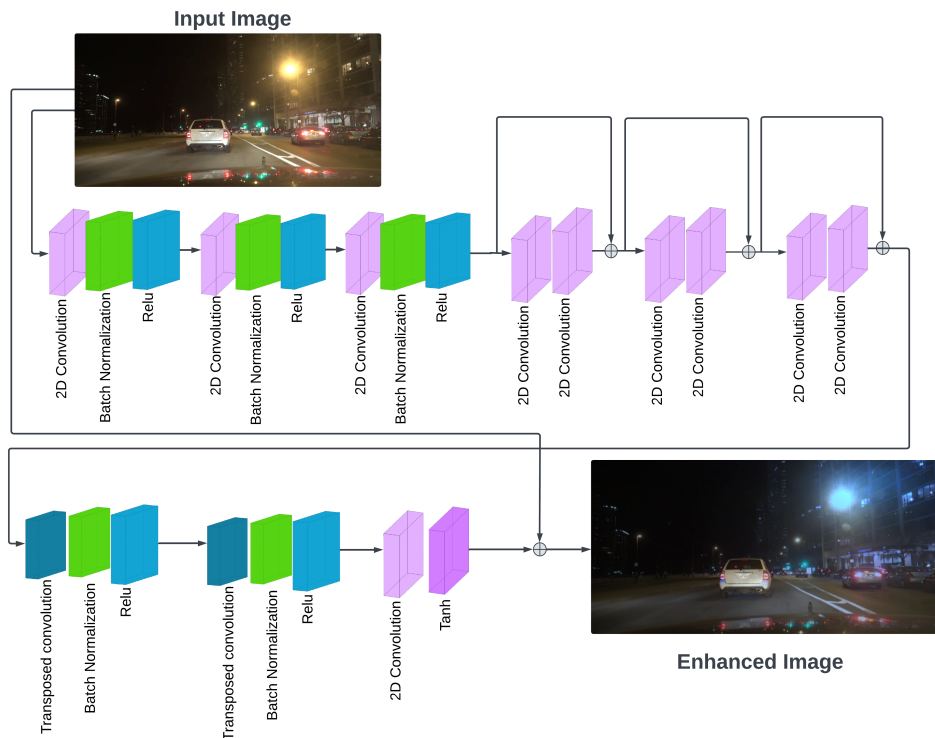

Fig. 1. Relighting Model

from many branches using techniques such as interpolation and summation to provide a comprehensive representation.

$$\text{Output} = \text{Concatenation}(F1, F2, F3, F4) \quad (3)$$

where:

- $F1$  represents the feature map extracted from stage 1
- $F2$  represents the feature map extracted from stage 2
- $F3$  represents the feature map extracted from stage 3
- $F4$  represents the feature map extracted from stage 4

The output from each stage from the 4 stages are processed through two  $1 \times 1$  convolutions, followed by batch normalization and ReLU activation, and finally producing the output with 19 channels, as shown in Figure 2.

#### D. Data Augmentation

Image transformations are crucial for data preparation in deep learning. Input images are converted into tensors and normalized to ensure consistent values, stability, and effective model training. Our data augmentation process includes cropping, resizing, and flipping to enhance dataset diversity and improve model generalization. The dataset's segmentation masks are transformed into tensor representations. The transformations are applied to the incoming data without issue, preparing it for further analysis and model training. This process ensures the model's success across various contexts.

### IV. DATASETS

#### A. Night-city

Night City [6], [17] is the largest available nighttime semantic segmentation dataset. It comprises 2,998 images at a

resolution of  $1024 \times 512$  for training and 1,299 images for validation. Each image comes with pixel-level annotations. However, there are noticeable annotation errors, such as missing labels and incorrectly labeled areas, which reduce the dataset's effectiveness. Additionally, [21] introduced NightCity-fine, an improved dataset derived from Night City for nighttime semantic segmentation. In this dataset, unreasonable annotations have been systematically corrected in both the training and validation sets.

#### B. Dark-Zurich

The Dark-Zurich dataset, a popular benchmark in computer vision and robotics research, is a collection of high-resolution images, primarily used for object detection and semantic segmentation tasks. The dataset features high-quality images with high spatial resolution, enabling detailed examination of urban environments. It includes a diverse range of urban scenes such as roads, crosswalks, buildings, green spaces, and other infrastructure. Additionally, many images are manually annotated with pixel-level labels, providing crucial ground truth annotations for semantic segmentation tasks. The dataset is well-suited for testing, comprising 8,377 images for training and 100 images for validation, evenly divided into 50 night and 50 day images. The test set includes 302 images, split into subsets for nighttime and daytime scenes, respectively.

#### C. Cityscape

The Cityscapes dataset is a comprehensive resource for urban scene understanding, featuring 5,000 high-resolution

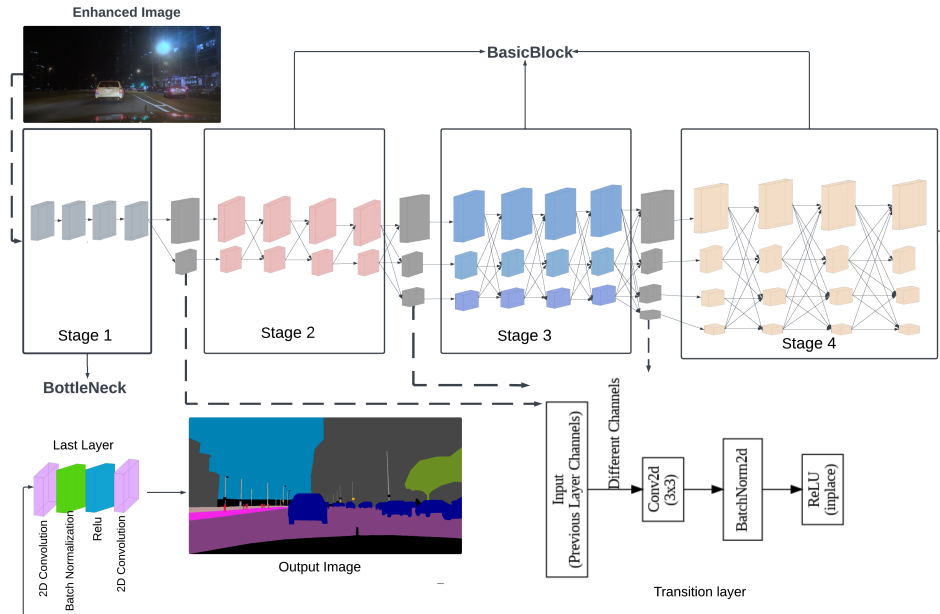

Fig. 2. Our HRNet Architecture

frames captured across diverse street scenes. It includes pixel-level annotations across 19 semantic categories, such as cars, pedestrians, roads, traffic signs, and buildings. The dataset’s landscape orientation ensures consistency and smooth integration into computer vision pipelines. With a resolution of  $2,048 \times 1,024$  pixels, the images provide sufficient detail for accurate semantic segmentation and scene understanding tasks. Divided into three subsets, the dataset offers sample data for model training, validation, and testing, with 2,975 images allocated for training, 500 images for validation, and 1,525 images for testing.

#### D. Experimental Design

We initiated our training by utilizing domain adaptation techniques on the Cityscapes and Dark Zurich datasets. Domain adaptation methods were employed to enhance the model’s performance on Dark Zurich images. Specifically, we utilized techniques such as adversarial training to align the feature distributions between the two domains, using the SGD optimizer. By adapting the model trained on Cityscapes to better generalize to Dark Zurich, our goal was to minimize the domain shift and improve the model’s robustness in low-light conditions. The results are shown in Table I. Additionally, we experimented with RHRSegnet on the NightCity-Fine dataset for training and obtained extremely good performance metrics without using domain adaptation approaches. Despite the lack of domain adaptation, the model showed proficiency in correctly classifying objects in night settings. This achievement demonstrates the adaptability and flexibility of RHRSegnet to changing environmental factors, especially low light levels, without requiring further domain-specific changes. The remarkable outcomes suggest that RHRSegnet has the ability to generalize effectively over a wide range of datasets,

highlighting its potential for practical use in tasks involving the analysis and segmentation of night scenes. Results evaluated on the Cityscapes dataset are shown in Table II.

#### E. Results

The benchmark results presented in Table I offer a comparison of different segmentation models based on their mean intersection over union (mIoU) performance in the context of Cityscapes  $\rightarrow$  Dark Zurich adaptation, evaluated on the Dark Zurich validation set. The first model, AdaptSegNet, employs the Deeplab architecture and achieves a modest mIoU of 20.2. The next two models, GCMA and MGCDA, utilize the RefineNet architecture, yielding mIOUs of 26.7 and 26.1, respectively, showcasing a notable improvement over AdaptSegNet. Notably, our model, RHRSegNet, stands out with the highest mIoU of 27.19, leveraging the HRNet architecture. This performance underscores the effectiveness of our model in handling domain adaptation challenges, particularly in challenging low-light conditions as represented in the Dark Zurich dataset. The results clearly highlight the superior performance of RHRSegNet, suggesting that our chosen architecture and model optimizations effectively enhance segmentation accuracy, outperforming the other competitive models in this challenging task. The benchmark results in Table II showcase a comparison of various segmentation models based on their mean intersection over union (mIoU) performance using the Cityscapes dataset for evaluation. RefineNet, an advanced segmentation network, achieves a respectable mIoU of 28.5. DeepLab-v2 and PSPNet, both well-known models in the domain, slightly outperform RefineNet, each with an mIoU of 28.8. However, our model, RHRSegNet, demonstrates a substantial improvement, achieving an impressive mIoU of 37.53. This result highlights the effectiveness of RHRSegNet

Method	Architecture	mIOU
AdaptSegNet [18]	Deeplab	20.2
GCMA [14]	RefineNet	26.7
MGDA [15]	RefineNet	26.1
RHRSegNet (Ours)	HRNet	27.19

TABLE I

Comparison by mIOU metric using Cityscapes  $\rightarrow$  Dark Zurich adaptation evaluated on Dark Zurich validation between our model RHRSegNet and other models

in segmenting complex urban scenes, significantly outperforming other models. The remarkable performance of RHRSegNet underscores its robust architecture and superior feature extraction capabilities, making it highly effective for semantic segmentation tasks, especially within urban environments as represented in the Cityscapes dataset.

Method	mIoU
RefineNet [9]	28.5
DeepLab-v2 [2]	28.8
PSPNet [24]	28.8
RHRSegNet	37.53

TABLE II

Comparison by mIoU metric using Cityscapes for evaluation

The benchmark results presented in Table III provide a comprehensive comparison of segmentation models across various categories based on their mean Intersection over Union (mIoU) performance using the Cityscapes and Dark Zurich datasets. Notably, the models evaluated include RefineNet, DeepLab-v2, PSPNet, AdaptSegNet, ADVENT, BDL, DMAda, and our proposed RHRSegNet with two variations: RHRSegNet-Cityscapes and RHRSegNet-NightCity-Fine. In terms of overall performance, RHRSegNet-Cityscapes clearly outperforms the other models with a remarkable mIoU of 37.53, showcasing exceptional segmentation accuracy, particularly in key categories like Road, Building, Sky, Car, and Bus. This reflects the robust architecture and superior feature extraction capabilities of RHRSegNet. The second variation, RHRSegNet-NightCity-Fine, also performs competitively with an mIoU of 33.35, highlighting its effectiveness in challenging low-light conditions. Among the competing models, DMAda demonstrates strong performance with an mIoU of 32.1, particularly excelling in categories like Rider and Car. Meanwhile, BDL achieves an mIoU of 30.8, showing solid results across several categories. The other models, including RefineNet, DeepLab-v2, PSPNet, AdaptSegNet, and ADVENT, achieve mIoUs below 30, indicating that they struggle more with the segmentation tasks, particularly in challenging urban and nighttime environments. Overall, the results highlight the superior performance of RHRSegNet, particularly in complex and challenging conditions, reaffirming its robust design and superior segmentation capabilities across a wide range of urban scene categories.

## V. CONCLUSION

The paper presents a novel model, RHRSegNet, for nighttime semantic segmentation using deep learning techniques and low-light-adapted algorithms. The model evenly distributes light, simulates changes in lighting conditions to improve brightness and contrast, and separates different factors in an image, such as lighting conditions and object colors. It also distinguishes between different features in an image, thereby improving image quality and processing images with multiple variables. The model is tested using the Night-City, Cityscape, and Dark-Zurich datasets, demonstrating its potential in handling complex lighting conditions and recognizing semantics even in challenging scenarios. This approach sets a stronger standard for evaluating segmentation throughout the night, enhancing the quality of computer vision applications like autonomous driving.
