**Working Paper**

**Abstract.** This research dissects financial equity research reports (ERRs) by systematically mapping their content into categories.

There is insufficient empirical analysis of the questions answered in ERRs. In particular, it is not understood how frequently certain information appears, what information is considered essential, and what information requires human judgment to distill into an ERR.

The study analyzes 72 ERRs sentence-by-sentence, classifying their 4940 sentences into 169 unique question archetypes. We did not predefine the questions but derived them solely from the statements in the ERRs. This approach provides an unbiased view of the content of the observed ERRs. Subsequently, we used public corporate reports to classify the questions' potential for automation. Answers were labeled "text-extractable" if the answers to the question were accessible in corporate reports.

78.7% of the questions in ERRs can be automated. Those automatable question consist of 48.2% text-extractable (suited to processing by large language models, LLMs) and 30.5% database-extractable questions. Only 21.3% of questions require human judgment to answer.

We empirically validate, using Llama-3-70B and GPT-4-turbo-2024-04-09 that recent advances in language generation and information extraction enable the automation of approximately 80% of the statements in ERRs. Surprisingly, the models complement each other's strengths and weaknesses well.

The research confirms that the current writing process of ERRs can likely benefit from additional automation, improving quality and efficiency. The research thus allows us to quantify the potential impacts of introducing large language models in the ERR writing process.

The full question list, including the archetypes and their frequency, will be made available online after peer review.

**Keywords:** applied natural language processing · text generation · question answering · generative AI · natural language processing · financial text

## 1 Introduction

This empirical study aims to estimate the automation potential when writing equity research reports (ERRs) by systematically classifying statements of equity researchers into categories, and subsequently evaluating which sections and statements in ERRs require human judgment. One of the key contributions is a question list that analysts answer in ERRs. This question list gives a holistic overview of the ERR topics. We classify each question’s automation potential by comparing the data sources to the statements to see whether an automated system could have written the ERRs. If the share of automatable questions is high, this study may indicate that the automation of large parts of ERRs is feasible.

ERRs are written mainly by sell-side banks and specialized research companies. The purpose of ERRs is ultimately to serve as a buy, hold, or sell recommendation (Asquith et al., 2005, p. 246). Two of the most common differences among ERRs are their content and intention. The content of ERRs can be to initiate a company’s coverage, provide an ordinary update to an already covered company, or provide an extraordinary update about a company. Subsequent recommendations to buy, hold, or sell may change or stay the same. One common update cycle for ERRs is quarterly ordinary updates. ERRs thus often contain recent facts from quarterly company-provided financial reports. Half of issued new ERRs generally fall into this category, being released closely after the company published new information (Asquith et al., 2005, p. 247). We review the literature on ERRs in section 2.1, discussing their importance, accuracy, and existing approaches for automation.

We created the question list by manually reading each sentence of 72 ERRs. We mapped each phrase in the reports to a question. When we encountered a new question, we added it to the list. The result is a histogram of question occurrences (figure 2). We provide more detail about the methodology in section 4.

This approach aligns with prior research (Asquith et al., 2005, p. 251), with the main difference being that we did not assume specific data fields (or questions) to be present in the reports ex-ante. Instead, we recorded each statement, derived a question from it, and counted the number of occurrences of each question. This approach ensures maximum unbiasedness in representing the landscape of ERRs.

No systematic reviews of ERR automation exist. News feeds for financial news are already partially generated by AI systems. However, the automation of ERRs is not yet widely automated, albeit being feasible (Coleman et al., 2022). Some consumer-grade analyst houses such as Zacks.com use template-based automation to update their company profiles and overview articles. Longer texts, however, are still written by humans. ERRs are one example of such longer texts, and they are the focus of this study.

## 2 Literature

### 2.1 Review of the Financial Economics Literature

Considering how strongly stock market prices react after ERRs are published, their importance for investors and, by extension, stock-listed corporations is evident in the literature (Bjerring et al., 1983; Elton et al., 1986; Liu et al., 1990; Beneish, 1991; Stickel, 1995).

Womack (1996) observed that analysts could predict the directionality of stock returns six months into the future (pp. 139, 163–165), indicating significant information content in ERRs. At least directionally, not necessarily with respect to the accuracy of the price targets, ERRs thus exhibit predictive accuracy higher than what can be expected from random guessing.

A persistent problem with the reliability of ERRs is the reluctance of analysts to present negative recommendations, as Barber et al. (2001) and Mikhail et al. (2004) demonstrated. Asquith et al. (2005) report a rate of sell recommendations of only 0.5% in an ERR sample from 1997 to 1999 (p. 255), while Womack (1996) report a rate of sell recommendations of 14% (p. 164) between 1989 and 1991. Prior research by Michaely and Womack (1999) concludes that the reason for the low number of sell recommendations is likely that the companies covered by many financial analysts are the banks' clients. Therefore, incentives arise to report too positively.

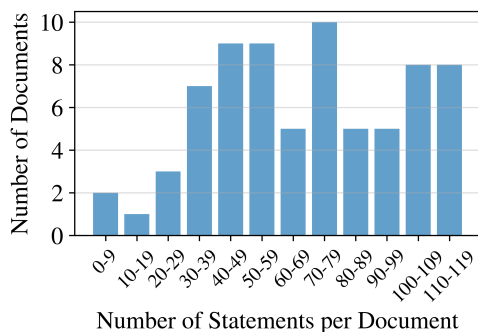

According to a study by Asquith et al. (2005), more than half (54%) of analyst reports set price targets that are achieved within a year (pp. 278–279). This accuracy rate appears relatively low, considering that the majority of ERRs tend to offer conservative recommendations, with price targets slightly exceeding current prices, on average (Asquith et al., 2005, p. 256). The authors did not judge whether the analysts' success rate was good or poor. In contrast to this outcome, Bradshaw et al. (2013) found that only 38% of analysts' price targets are met within a one-year horizon (pp. 953–954). Bonini et al. (2010) provide another critical analysis of financial analysts' accuracy (pp. 1177, 1193–1196, 1208). The unequivocal findings potentially strengthen the argument for automating ERRs to achieve more robust price targets (Gleason et al., 2013, pp. 80–81, for further discussion on report accuracy).

Research by Coleman et al. (2022) shows that these issues can be mitigated by using a hybrid machine-human approach. The study presents a computer-aided approach that better balances the buy, hold, and sell recommendation frequencies, achieves better portfolio performance, and reduces the time required for writing reports.

The previously presented studies show that the importance and accuracy of ERRs are studied extensively. Furthermore, there is extensive research on how stock performance is predicted by systematic factors, notably factor models by Eugene Fama and French (1992, 1995, 2018, 2015) and by other studies from the field of risk factors and asset pricing (Carhart, 1997; Asness et al., 2013).

Asquith et al. (2005) performed a similar empirical analysis as our study. They ex-ante determined 30 variables of interest that were extracted from ERRs. There are differences in the objective, the data, and the methodology when comparing Asquith et al. to our study. They examined the accuracy of ERRs, how much they impact markets, and how independent research providers compare to sell-side banks. The data is from 1997 to 1999, and they selected only a subset of high-performing analysts. Also, they derived the 30 data fields from the objective before reading the ERRs; in this study, however, we read the ERRs and generated the questions ad-hoc when encountering new questions.

**Fig. 1. Histogram With Statement Counts in ERRs by Frequency.** ERRs rarely have less than 30 statements. Most reports have between 30 and 119 statements.

## 2.2 Review of the Technical Literature

Question answering (QA) systems commonly use text retrieval. Text retrievers get a question or a topic as input and search for fitting segments from a knowledge base. The retrieved span of text can be used directly as the answer or can be postprocessed by another system. Text retrieval from financial statements, even in combination with text from table captions, is already implemented by Chen et al. (2021). As retrievers are capable of choosing facts from knowledge bases of practically unlimited size, they are a key lower-level component needed to enable fact-based automated writing Borgeaud et al. (2021). It thus remains a core technology for automated ERR writing, at least until large language models' context sizes become larger than they are today (Chen et al., 2023).

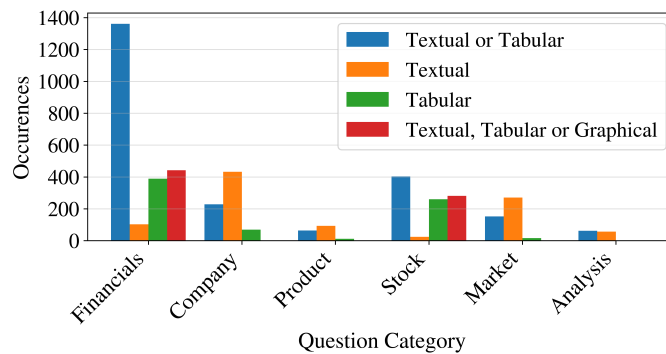

As the stated goal of this study is to pave the way for automating the writing of ERRs, we provide a brief overview of the QA literature. QA is a subfield of natural language processing (NLP). It can be one of the domains that facilitate the automation of ERR writing.

Dense passage retrieval uses latent representation of the question to search for an answer in a large corpus of text Karpukhin et al. (2020). Combining such a retrieval mechanism with a generative language model by including the retrieval outputs to the language model prompt, one gets a retrieval-augmented generator (RAG) as presented by Lewis et al. (2020). RAG continues to receive attention from the research community, as follow-up research on the topic shows (Izacard et al., 2022; Guu et al., 2020; Borgeaud et al., 2021). Its effectiveness in writing factually correct and fluent text makes RAG a technology that may facilitate the automation of ERR writing.

With the emergence of the mentioned RAG methods, generative models are better capable of performing QA tasks. Furthermore, as models and their training data scale, their ability to store knowledge in their parameters increases, making them capable QA models even without external knowledge bases, as GPT-3 Brown et al. (2020) and the Llama models Touvron et al. (2023) demonstrate. In addition, advances in the expansion of the context length (Press et al., 2022; Chen et al., 2023) make it possible to provide more world knowledge into prompts.

**Fig. 2. Histogram of Category Frequency, Grouped by Question Category.**

The histogram shows how frequently different information is displayed, grouped by question category. ERRs contain the financial category most frequently and usually display this category in text-or-tabular format or in text-tabular-or-graphical or tabular format. Company and market information are commonly in text-only format. Notably, stock information is rarely in text-only format. Only 2.82% of questions (weighted by their number of occurrences) were exclusively displayed in graphical format.

As the general capabilities of language models grow, finance-specific language models also improve. Wu et al. (2023) develop a language model capable of

understanding the nuances of a financial text. About half of their training data is finance-specific. The model performs well on financial QA (pp. 31–32). These generative language model developments increase the capabilities of state-of-the-art language models to generate factually correct ERRs.

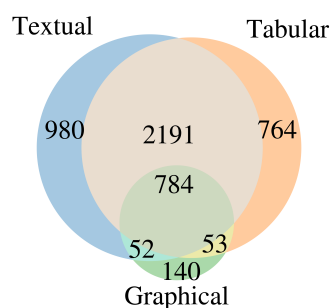

### 3 Data

We downloaded the ERRs dated from 2018 to 2023 from Bloomberg and Refinitiv Eikon. Each of the 72 reports had an average of seven pages, with the median being 6.8 pages per report. The shortest report is a one-pager, and the longest report has 20 pages. See also figure 8 for a histogram of page counts. We analyzed 493 pages across all reports. These statistics are in line with findings of previous research by (Asquith et al., 2005, p. 252). We sourced the ERRs from 23 different research providers, each contributing between 1 and 16 reports (figure 3).

The number of statements per report ranges from nine to 115. The average is 68, and the median is 69. See also figure 1 for a histogram of statement counts. In sum, we analyzed 4940 statements (sentences).

### 4 Methods

**Fig. 3. Display type of Statements in the ERRs.** The Venn diagram shows how information is conveyed in ERRs. About half of the statements can be made in either textual or tabular form. 980 statements only appear in text form, and 764 statements always appear in tables. Only relatively few statements, mostly related to stock price history and other market data, are only displayed in graphical form.

## 4.1 Question List and Question Categories

The annotation process was bias-free, without presumptions about the space of questions we would encounter. Sentence-by-sentence, we read the ERRs and annotated each sentence with a question. When we encountered an answer to a question that we previously saw, we mapped the statement to the existing question. When a question was not on the list, we added a new question.

We grouped the resulting 169 questions into five categories. The categories are: *Financials*, *Company*, *Product*, *Stock*, *Market*, *Analysis*. The questions are listed in tables 4-7.

## 4.2 Question Classification

To make use of this question list for our purpose of analyzing the automation potential of ERRs, we classified each unique question in two dimensions:

1. **Extractability:** If the answer to a question is found in a corporate report, the question is extractable. To validate that our classification of extractability is correct, we ran the open-source Llama-3-70B model and the closed-source GPT-4-turbo-2024-04-09 model on 200 example questions, showing that these language models can indeed extract the answers to the questions when provided with annual reports as the prompt context. We describe this validation step in 4.4.
2. **Display Modality:** Refers to how analysts display the statement. The results are reported in figure 3, showing that most information can be displayed in text or tabular form.

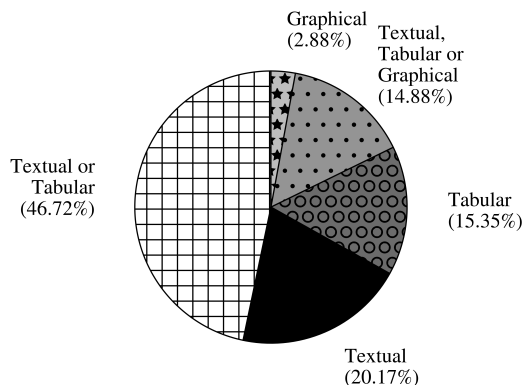

The aggregated results are in table 2 and the original flags are in tables 4-7. We used company-issued reports to check whether the questions are extractable.

The annotation process required two iterations of reading through the reports. In the first reading process, the question list was created. In the second iteration, we labeled the extractability and the modality columns. The second iteration involved reading the ERRs again, and finding the source for the answer to each question. If a direct answer was matched in a single source, the extractability was marked as “extractable.” If the answer was not found in a single passage, the extractability was marked as “non-extractable.”

## 4.3 Qualitative Validation of the Question List Using Expert Interviews and Prior Research

We conducted interviews with ten financial analysts. Each interview lasted 45 minutes. The interviews aimed to validate the relevance of our results and confirm whether the count-based ranking of questions was realistic. In the interviews, we were reassured that our results align with what would be expected in practice when considering the most important questions in ERRs. In some interviews, however, it became clear that financial analysts consider the management qualifications and subjective impressions about the competence of managers.

**Fig. 4. Frequency of Different Modes of Data Representation in ERRs.** The two categories “Tabular or Graphical Data” (53 occurrences) and “Textual or Graphical Data” (52) were filtered out as only very few questions are represented in these ways.

This aspect is not captured in this study and will be hard to capture for automated systems.

In addition to validation through qualitative interviews, prior research by Asquith et al. (2005, p. 246) confirms that the top questions identified in our study match their findings about the most frequent ERR contents.

#### 4.4 Validation of the Automation Potential by Comparing Human, Llama-3-70B, and GPT-4-turbo-2024-04-09 Report Generation Performance

We validate the claims made in this paper about the automation potential of specific questions by automating parts of the report generation. We test which questions are the hardest questions for language models to answer, which informs our assessment of the question “extractability.”

We use the open-source Llama-3-70B model by Meta AI and the closed-source GPT-4-turbo-2024-04-09 model by OpenAI. We set the temperatures of both models to zero (giving the models the chance to always use their true best guesses) and do not limit the number of output tokens. In cases where the context lengths of the models were exceeded, we split the contexts and concatenated the models’ outputs.

Our results show that Llama-3-70B is able to extract information from annual reports in 27% of the 200 questions. GPT-4 is able to extract the correct answer in 26% of the questions. The results are in line with our expectations and confirm that the models can indeed extract the answers to the questions when provided with annual reports as the prompt context.

If one adds the database-extractable questions, which can be gathered automatically from financial data providers, the share of automatable questions rises

**Fig. 5. Share of Correct, Incorrect, Database-Extractable, and Non-Extractable Questions for GPT-4-turbo-2024-04-09 and Llama-3-70B.** Stock-related questions can only be answered using financial market data. Those thus fall under a separate category that is automatable, yet not by using language models. Llama 3 has a slight edge over GPT-4 as it answered more questions correctly than GPT-4 did.

to  $55\% + 26\% = 81\%$  for GPT-4, and  $82\%$  for Llama 3. If one then also considers that the models' performance is highly uncorrelated, one could use both models at once to achieve an ensemble that can answer  $84\%$  of questions, and makes mistakes only for about  $1\%$  of questions (see also figure 6).

As a qualitative side note, we found that GPT-4 tends to provide longer responses with more context. In some cases, we thus found that GPT-4 provided helpful context that Llama-3-70B missed. We performed some follow-up tests with Llama 3 to see if this difference was a lack of capability or simply a difference in the default verbosity among the models. We found that, for the purpose of financial text, Llama 3 is able to provide the same extraction depth and abstraction capabilities as GPT-4 does. But Llama 3 tends to provide more direct answers compared to GPT-4 unless prompted to add contextual flavor. Also, Llama often attempts to calculate growth numbers when asked about rates. In all attempts, it fails to provide correct absolute or relative year-on-year changes, but stays in the correct ballpark of plus/minus  $10\%$ .

The language models correctly identified information in full-form text and in tabular format. Tables were simply copy-pasted from the annual reports, so that the formatting of these tables was not specifically optimized language model readability. The models showed high robustness in extracting financial information from tables. For each mistake made by the language models, we inspected the context to see if a human had been able to answer the question given the text-only context (no PDF formatting was provided, limiting what the language models were able to see relative to what a human would be able to infer from a text's context in the annual report). We made sure that no language model answer was marked as incorrect if there was no clear answer in the context, but no such cases occurred in the sample of 200 questions.

**Fig. 6. Correctness of Answers by GPT-4-turbo-2024-04-09, Llama-3-70B, and the Best of Both Models.** The green parts show correct answers, the red-white-hatched parts show errors. Interestingly, the errors of GPT-4 and Llama 3 have almost no overlap. When one model is unable to correctly answer a question, the other model usually is. There was only one question that both models did not answer correctly despite the relevant information being present in the prompt. The fine black lines in the right plot delimit different questions, and the culmination of errors for certain questions shows that the models have difficulty with particular questions.

## 5 Results

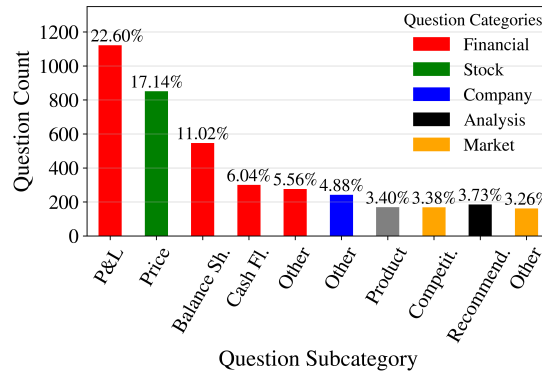

### 5.1 Result Overview

In summary, 78.7% of the 169 questions in ERRs are automatable. 48.2% of the statements in ERRs are extractable. 30.4% of questions require access to non-public databases but have potential for automation. Only 21.3% of questions require judgment that goes beyond extraction.

### 5.2 Analysis of Question Categories and Subcategories

A share of 73.4% of statements in the category *Product* are automatable. The most critical question category by statement count is the *Financials*. 70.6% of statements from this category are extractable. A share of 54.6% is automatable in the category *Company*. A share of 16.6% is automatable in the category *Stock*. A share of 4.6% is automatable in the category *Market*. This is because statements about the market environment usually require access to diverse sources outside the company’s annual and quarterly reports. None of the statements from the *Analysis* category can be automated with extractions from publicly available corporate reports. This category contains the target price (forward guidance), recommendation, and risk assessments.

**Fig. 7. Share of Question Subcategories.** Please note that there are three “Other” labels on the x-axis. These refer to the “Other” subcategory of their respective categories: “Financial – Other,” “Company – Other,” and “Analysis – Other.”

**Table 1. Question Frequency List of the Five Most Frequently Answered Questions.** The table indicates which types of statements are the most frequent across all ERRs. Across the 72 reports, 66 contained information about the stock price and 65 about the company’s challenges. Company details and market environment statements appear less frequently.

# Question	Count Subcategory	Numerical	Extractable From Text
1 Stock price	66 Stock - Price	Yes	No
2 Potential challenges	65 Company - Other	No	No
3 Primary industry	64 Product	No	Yes
4 Analyst score	64 Financials - Other	No	Yes
5 Earnings per share	62 Financials - Financing	Yes	Yes

**Table 2. Overview of Extractable and Non-extractable Statements.** Numeric-extractable statements have a share of 40%. Numeric-**non**-extractable statements have a share of 26%. Almost two-thirds of non-numeric statements are non-extractable.

Counted by the number of unique questions:		
	Numeric	Non-Numeric
Extractable From Text	67 (40.61%)	17 (10.3%)
Not Extractable	42 (25.45%)	39 (23.64%)

Counted by the total number of statement occurrences:		
	Numeric	Non-Numeric
Extractable From Text	1925 (38.78%)	437 (8.8%)
Not Extractable	1425 (28.71%)	1177 (23.71%)

### 5.3 Analysis of Extractable and Non-Extractable Statements

Table 2 portrays the classifications of questions answered in the examined ERRs. The x-axis shows whether the questions answered are numeric or non-numeric. The y-axis exhibits whether the information gained is extractable from another source of non-written text.

Two-thirds are numeric, and more than half are extractable. While extractable information is mostly numeric (40%), extractable non-numeric information is rare (12%). Out of the non-extractable information, slightly more is numeric.

### 5.4 Analysis of Contextualizing and Summarizing Components

The *Analysis* question category contains mostly summarizing and contextualizing components. Given the same set of facts, different analysts may weigh, select, and combine those facts differently, leading to different recommendations.

Related to this, there are numerous questions in the category *Market* of this nature. Market developments require simplification and curation to distill into a few pages of text. Similar to the *Analysis* category, different observers judge the same set of facts differently, leading to different conclusions. Given that the potential inputs to this category are vast, with many news reports and other sources to choose from, it is unlikely that an automated system can already handle this task.

### 5.5 Tabular Data

Most statements in ERRs are textual or tabular. Chen et al. (2021) show that numerical reasoning across tables and text is feasible (pp. 5–7). Zhu et al. (2021) confirm that tabular information extraction is possible, particularly for financial data (pp. 3282–3284).

We confirm these findings: Our validation from section 4.4 has not required any manual formatting of table data – we copied tables from annual reports without formatting into the models’ context, and they extracted information from these ill-formatted strings with high reliability.

## 6 Conclusion

Our results confirm the findings by Coleman et al. (2022) that partly automating equity research reports (ERRs) is feasible. Only 21.3% of questions require complex judgment that takes into consideration more information than would fit in a language models’ context window.

In particular, the *Analysis* category in ERRs contains summarizing statements that make recommendations. These statements are not extractable from other sources. Only 3.5% of statements in ERRs fall under the analysis category. Given the oversized importance of this category, and given that humans may, for the time being, still be better at providing high-stake recommendations, this category should be left to human financial analysts.

Figure 2 shows that, without weighting the questions by their occurrence frequency, 48.2% of questions answered in ERRs can be answered by extracting information from public textual sources. An additional 30.4% are available in proprietary market data sources.

Our counting approach does not weigh the importance of the questions. The most important questions may appear less frequently. Furthermore, there could be out-of-distribution questions that we did not capture in this analysis because they were not present in the ERRs we analyzed.

Only 72 ERRs from 23 research firms were dissected. Other research firms may include questions not in the space of 169 question archetypes identified in this study.

Direct information extraction from ERRs is still a largely unexplored field. Various approaches were presented in section 2.1. Future research can implement these methods.

**Fig. 8.** The histogram shows how frequent certain page counts are among the equity research reports (ERRs). We identified two ERRs with one page and one ERR with two pages. Then, starting with three pages, the number increases significantly, with most ERRs having between three and nine pages. The longest report has 20 pages.

**Table 3.** J.P. Morgan provided the most equity research reports for this analysis with 16 pieces, followed by Deutsche Bank (9), Zacks (8), Barclays (7) and Mizuhu (5). GlobalData and China Renaissance have one report each, with 115 and 106 statements for each of these reports. J.P. Morgan wrote 93, while Zacks wrote 90 and Phillip Securities Research 78 statements per report on average. The average number of statements is 68.6, the median is 70, and the minimum number is a result of Veritas Investment Research's one-pager with only nine statements.

Research Provider	Research Report Counts	Avg. No. Statements per Report
J.P. Morgan	16	93
Deutsche Bank	9	56
Zacks	8	90
Barclays	7	63
Mizuho	5	48
Needham	5	71
KBW	3	55
Refinitiv	2	53
New Constructs	2	40
Phillip Securities Res.	2	78
GlobalData	1	115
China Renaissance	1	106
IBM Res.	1	34
Punto Casa de Bolsa	1	24
Spartan Capital	1	58
Thompson Res.	1	34
Mitsubishi UFJ M.S.	1	31
Oppenheimer	1	44
BPC Res.	1	44
Veritas Investment	1	9
Echelon	1	59
finnCap	1	75
BTIG	1	69

**Table 4.** Question ranking table 1 of 4 with the top questions by frequency, ranks 1–50. The table is a question frequency list of the first 50 of the 169 unique questions derived from factual statements and predictive assessments from equity research reports (ERRs). The table indicates which types of statements are the most frequent across all equity research reports. Across the 72 reports, 66 contained information about the stock price and 65 about the company’s challenges. The less frequent questions refer to more detailed statements about the company and its market environment. The low frequency of these questions indicates that the basic questions displayed in the table are the main focus of most ERRs.

#	Question	Count	Subcategory	Numerical	Extractable From Text
1	Key financials	122	Financials - Other	Yes	Yes
2	Analyst rating/buy or sell recommendation	64	Analysis - Recommend.	No	No
