Abstract

This paper investigates the distributionally robust filtering of signals generated by state-space models driven by exogenous disturbances with noisy observations in finite and infinite horizon scenarios. The exact joint probability distribution of the disturbances and noise is unknown but assumed to reside within a Wasserstein-2 ambiguity ball centered around a given nominal distribution. We aim to derive a causal estimator that minimizes the worst-case mean squared estimation error among all possible distributions within this ambiguity set. We remove the iid restriction in prior works by permitting arbitrarily time-correlated disturbances and noises. In the finite horizon setting, we reduce this problem to a semi-definite program (SDP), with computational complexity scaling with the time horizon. For infinite horizon settings, we characterize the optimal estimator using Karush-Kuhn-Tucker (KKT) conditions. Although the optimal estimator lacks a rational form, *i.e.*, a finite-dimensional state-space realization, it can be fully described by a finite-dimensional parameter. Leveraging this parametrization, we propose efficient algorithms that compute the optimal estimator with arbitrary fidelity in the frequency domain. Moreover, given any finite degree, we provide an efficient convex optimization algorithm that finds the finite-dimensional state-space estimator that best approximates the optimal non-rational filter in \mathcal{H}_{∞} norm. This facilitates the practical implementation of the infinite horizon filter without having to grapple with the ill-scaled SDP from finite time. Finally, numerical simulations demonstrate the effectiveness of our approach in practical scenarios.

1 Introduction

The Kalman filter (KF), introduced by Rudolf Kalman in 1960 [1], is a fundamental tool for estimating dynamic signals generated by state-space models from noisy measurements. It has become indispensable across various fields, such as tracking [2, 3], navigation [4, 5], robotics [6–8], autonomous vehicles [9, 10], aerospace [11–13], earth sciences [14–17], biomedicine [18–20], economics and finance [21–23]. Its efficacy hinges heavily on accurately modeling state-space parameters and noise statistics, which often deviate from the actual model due to statistical and approximation errors, inherent environmental uncertainties, and non-stationarities. These deviations can severely degrade performance [24–26], posing severe risks in safety-critical applications such as aircraft navigation and autonomous vehicles. Therefore, enhancing the robustness of the Kalman filter against inaccuracies and uncertainties is crucial for ensuring safe and reliable operation.

Traditionally, robustness in the Kalman filter has been addressed by treating uncertainties as adversarial, deterministic perturbations. In this context, the H_{∞} -filter [27–33] has garnered extensive research, driven by significant advances in robust control theory [33–36]. The H_{∞} -filter enhances robustness by minimizing the worst-case mean-squared estimation error (MSE) attainable among all bounded energy (or power) disturbances. Although these uncertainties are presumed to arise from exogenous disturbances, the optimal H_{∞} -filter also ensures robustness against small modeling errors in state-space parameters [37]. More recently, regret-optimal filtering [38, 39] has been introduced to balance performance and robustness. Unlike the H_{∞} -filter, it minimizes the worst-case regret, defined as the excess error a causal estimator suffers compared to a clairvoyant estimator, among all bounded energy disturbances. While effective against large uncertainties, these filters neglect distributional information and may become overly conservative when faced with stochastic disturbances [40].

Distributionally robust (DR) estimation and filtering offers an alternative framework that addresses the limitations of traditional robust filtering. Pioneered by Kassam and Poor [41, 42] in the context of Wiener filtering [43], this approach enhances robustness against uncertainties through the use of ambiguity sets of plausible statistical models. The behavior of the resulting robust filter is intricately tied to the topology of the ambiguity set, which is often constructed as a ball induced by a statistical distance or divergence. Examples include the total variation (TV) distance [44, 45], the Kullback-Leibler (KL) divergence [46-49], and the Wasserstein-2 (W₂) distance [50-56]. The filters derived from KL-ambiguity sets have been linked [46, 47, 57, 58] to risk-sensitive filters [59–62, 32], which minimize the exponentiated squared estimation error. A significant drawback of KL-ambiguity is its limited expressivity, as it only includes distributions whose support matches the nominal distribution [63]. Due to its geometric interpretability as the optimal transportation metric [64], the W_2 -distance has recently seen widespread adoption across various fields, including machine learning [65], computer vision [66, 67], control [68–73], data compression [74–76], and robust optimization [77-83]. W2-ambiguity sets offer richer expressivity, encompassing distributions with both discrete and continuous support. The W2-distance also renders computationally tractable formulations for problems involving quadratic objectives, such as least mean-squared estimation [84], and linear-quadratic control [68].

1.1 Related Works

Recognizing these advantages, Shafieezadeh Abadeh et al. [50] introduced a distributionally robust Kalman filter based on W_2 -ambiguity sets confined to Gaussian distributions only. They derive state estimates at local time instances by minimizing the mean-squared error for the least favorable joint posterior distribution of the state-measurement vector, given past measurements. This iterative procedure, assuming iid Gaussian disturbances, incorporates the worst-case covariance of the previous state estimate into the nominal model for the subsequent time step. However, while this method inherently addresses state-space parameter mismatches, it lacks a global robustness guarantee over the entire time horizon and against non-iid or non-Gaussian disturbances. Similar temporally local approaches have also been studied in [51–53]. More recently, Lotidis et al. [55] took a different approach by imposing distributional uncertainty on the measurement noise process over the entire time horizon, assuming known iid process noise with known covariance. While the resulting filter demonstrates global robustness over the entire time horizon, the adversarial measurement noise is constrained by martingale conditions to prevent clairvoyance and dependence on future process noise realizations. Moreover, the assumption of known iid process noise.

1.2 Contributions

In this work, we consider the Wasserstein-2 distributionally robust Kalman filtering (W_2 -DR-KF) of linear state-space models for both finite and infinite horizons. The probability distribution of the disturbances over the entire time horizon is assumed to lie in a W_2 -ball of a specified radius centered at a given nominal distribution. We seek the optimal causal linear estimator of a target signal that minimizes the worst-case MSE within the W_2 -ball. We cast this as a min-max optimization problem (Problem 2.3, Problem 2.6). Our approach differs drastically from the prior works [50–53, 55] and possesses several advantages which can be listed as follows:

1. Global robustness to non-iid disturbances: In contrast to focusing on the worst-case MSE at local time instances under unknown iid disturbances [50–53], our approach minimizes the cumulative

MSE under the worst-case disturbance trajectory, thereby achieving global robustness for the entire horizon. Moreover, unlike [55], we impose no restrictions on the dependencies of the disturbances, accommodating arbitrarily correlated process and measurement noise sequences.

2. Bounded steady-state error: We derive the first infinite-horizon (aka steady-state) W_2 -DR-KF, analogous to the steady-state Kalman and H_{∞} -filters [85, 33]. We show that the estimation error converges to a steady state (Corollary 3.9) with bounded covariance.

3. Efficient real-time implementation: The finite-horizon W_2 -DR-KF requires solving an ill-scaled SDP (Theorem 3.4), rendering it impractical for real-time implementation over long time horizons. However, our infinite-horizon W_2 -DR-KF can be implemented efficiently, thanks to our novel rational approximation, thereby overcoming the scalability issues of SDP formulation.

Our contributions are summarized as follows:

1. Tractable convex formulation: We derive an SDP (Theorem 3.4) formulation for the finite-horizon problem, and a concave-convex max-min optimization problem over positive-definite Toeplitz operators (Theorem 3.8) for the infinite horizon one.

2. Optimality of linear estimators for Gaussian nominal: We focus on linear estimators while allowing the distributions in the ambiguity set to be non-Gaussian. For Gaussian nominal distributions, we show the optimality of linear estimators (Theorem 3.1).

3. Characterization of the infinite-horizon DR-KF: We derive the infinite-horizon W_2 -DR-KF via KKT conditions (Theorem 3.8) and show that the transfer function of the infinite-horizon W_2 -DR-KF is non-rational, and thereby lacks a finite-order state-space realization. However, we also show that it can be uniquely characterized through a nonlinear finite-dimensional parametrization (Lemma 4.1).

4. An efficient algorithm to compute the optimal filter: Using frequency-domain techniques, we introduce an efficient algorithm, based on the Frank-Wolfe method, to compute the optimal infinite-horizon W₂-DR-KF (Algorithm 1). We construct the best rational approximation, in the H_{∞} -norm, of any given degree, for the non-rational optimal W₂-DR-KF via a novel convex program (Theorem 4.6).

Notations: Bare calligraphic letters (\mathcal{K} , \mathcal{M} , etc.) are reserved for operators, with the subscripted ones (\mathcal{K}_T , \mathcal{M}_T , etc.) being finite-dimensional. \mathcal{I} is the identity operator with a suitable block size. Asterisk \mathcal{M}^* denotes the adjoint of \mathcal{M} . \succ is the usual positive-definite ordering. tr(·) is the trace. $\|\cdot\|$ is the usual Euclidean norm. $\|\cdot\|_{\infty}$ and $\|\cdot\|_2$ are the H_{∞} (operator) and H_2 (Frobenius) norms, respectively. $\{\mathcal{M}\}_+$ and $\{\mathcal{M}\}_-$ denote the causal and strictly anti-causal parts. $\sqrt{\mathcal{M}}$ is the positive-definite symmetric square root. \mathbb{S}^n_+ is the set of psd matrices. |z| is the magnitude and z^* is the conjugate of a complex number $z \in \mathbb{C}$. The complex unit circle is denoted by \mathbb{T} . \mathbb{P} denotes a probability distribution and \mathscr{P}_p is the set of distributions with finite p^{th} moment. \mathbb{E} denotes the expectation. The Wasserstein-2 distance between distributions $\mathbb{P}_1, \mathbb{P}_2 \in \mathbb{R}^n$ is denoted by $W_2(\mathbb{P}_1, \mathbb{P}_2)$ such that

$$\mathsf{W}_{2}(\mathbb{P}_{1},\mathbb{P}_{2}) \triangleq \left(\inf \mathbb{E}\left[\|\mathbf{w}_{1} - \mathbf{w}_{2}\|^{2}\right]\right)^{1/2},\tag{1}$$

where the infimum is over all joint distributions of $(\mathbf{w}_1, \mathbf{w}_2)$ with marginals $\mathbf{w}_1 \sim \mathbb{P}_1$ and $\mathbf{w}_2 \sim \mathbb{P}_2$.

2 Problem Setup

In this section, we formulate the distributionally robust filtering problem for both finite and infinite horizon settings. To this end, consider the following state-space model:

$$x_{t+1} = Ax_t + Bw_t,$$

$$y_t = C_y x_t + v_t,$$

$$s_t = C_s x_t,$$

(2)

At time $t \in \mathbb{N}$, let $x_t \in \mathbb{R}^{d_x}$ denote the unobserved *latent state*, $y_t \in \mathbb{R}^{d_y}$ the *measurement*, $s_t \in \mathbb{R}^{d_s}$ the unobserved *target signal* to be estimated, $w_t \in \mathbb{R}^{d_w}$ the *process noise*, and $v_t \in \mathbb{R}^{d_v}$ the *measurement noise*. The combined process-measurement noise sequence constitutes the *exogenous disturbance*. The setup presented above is quite general and widely adopted in the estimation and filtering literature [33, 85]. The usual state estimation problem is a specific instance of this setup with $C_s = I$. Moreover, we assume that (A, C_y) and (A, C_s) are detectable and (A, B) is controllable.

We take a global view of the dynamics (2) by treating the entire signal trajectories over a fixed time horizon T > 0 as large column vectors. Concretely, we define the measurements vector $\mathbf{y}_T := [y_0; y_1; \ldots; y_{T-1}] \in \mathbb{R}^{Td_y}$, the target signal vector $\mathbf{s}_T := [s_0; s_1; \ldots; s_{T-1}] \in \mathbb{R}^{Td_s}$, the process noise vector $\mathbf{w}_T := [x_0; w_0; \ldots; w_{T-2}] \in \mathbb{R}^{d_x + (T-1)d_w}$, and the measurement noise vector $\mathbf{v}_T := [v_0; v_1; \ldots; v_{T-1}] \in \mathbb{R}^{Td_v}$. Notice that the initial state x_0 is considered unknown and included in the vector of process noise, \mathbf{w}_T , for convenience. With the prevailing notation, the state-space dynamics can be represented compactly as a *causal linear measurement model*:

$$\mathbf{y}_T = \mathcal{H}_T \mathbf{w}_T + \mathbf{v}_T, \mathbf{s}_T = \mathcal{L}_T \mathbf{w}_T,$$
(3)

where \mathcal{H}_T and \mathcal{L}_T are both *block causal* (*i.e.*, block lower-triangular) matrices. These matrices can be constructed easily from the state-space parameters (A, B, C_y, C_u) (see Appendix B.1). This representation is quite general and can be extended immediately for time-varying state-space models with appropriately constructed matrices \mathcal{H}_T and \mathcal{L}_T .

Letting the stacked column vector $\boldsymbol{\xi}_T := [\mathbf{w}_T; \mathbf{v}_T] \in \Xi_T$ denote the combined disturbances where $\Xi_T := \mathbb{R}^{d_x + (T-1)d_w + Td_v}$, the disturbances $\boldsymbol{\xi}_T$ are distributed according to an unknown distribution $\mathbb{P}_T \in \mathscr{P}_2(\Xi_T)$. Note that the disturbances can be arbitrarily correlated in general. Wlog, we will assume $\boldsymbol{\xi}_T$ to be zero-mean for convenience. Our main assumption for \mathbb{P}_T is as follows:

Assumption 2.1. The true distribution \mathbb{P}_T of disturbances ξ_T resides in a W₂-ball,

$$\mathscr{W}_{T}(\mathbb{P}_{T}^{\circ},\rho_{T}) \coloneqq \left\{ \mathbb{P}_{T} \in \mathscr{P}_{2}(\Xi_{T}) \mid \mathsf{W}_{2}(\mathbb{P}_{T},\mathbb{P}_{\circ,T}) \leq \rho_{T} \right\},\tag{4}$$

where $\rho_T > 0$ is a specified radius and $\mathbb{P}_T^{\circ} \in \mathscr{P}_2(\Xi_T)$ is a given nominal disturbance distribution.

Remark 2.2. Although the state-space parameters (A, B, C_y, C_s) are assumed to be known perfectly, uncertainty in them can be incorporated into the disturbances without loss of generality.

2.1 The Finite-Horizon Distributionally Robust Filtering

A filtering policy $\pi_T := \{\pi_t \mid t = 0, \dots, T-1\}$ is a sequence of mappings that generate estimates \hat{s}_t of s_t from the past and present measurement as $\hat{s}_t = \pi_t(y_t, y_{t-1}, \dots, y_0)$. In particular, we focus on *linear filtering policies* $\mathcal{K}_T : \mathbf{y}_T \mapsto \hat{\mathbf{s}}_T$ such that $\hat{\mathbf{s}}_T = \mathcal{K}_T \mathbf{y}_T$ where $\hat{\mathbf{s}}_T := [\hat{s}_0; \hat{s}_1; \dots; \hat{s}_{T-1}]$ is the the column vector of estimates. We denote the class of all such policies by \mathcal{K}_T , defined as

$$\mathscr{K}_T \triangleq \left\{ \mathcal{K}_T \in \mathbb{R}^{T\mathsf{d}_s \times T\mathsf{d}_y} \mid \mathcal{K}_T \text{ is block lower-triangular} \right\}.$$
(5)

The restriction to linear filters is a common strategy in estimation literature, as general nonlinear estimators can be challenging to compute [85]. Additionally, linear filters are optimal for Gaussian processes. In Theorem 3.1, we establish the optimality of linear filters when the nominal is Gaussian.

For a filtering policy \mathcal{K}_T , let $\mathbf{e}_T(\boldsymbol{\xi}_T, \mathcal{K}_T) \triangleq \widehat{\mathbf{s}}_T - \mathbf{s}_T = \mathcal{T}_{\mathcal{K}_T} \boldsymbol{\xi}_T$ be the estimation error where $\mathcal{T}_{\mathcal{K}_T} : \boldsymbol{\xi}_T \mapsto \mathbf{e}_T$ is the *error transfer operator* defined as

$$\mathcal{T}_{\mathcal{K}_T} \triangleq \begin{bmatrix} \mathcal{K}_T \mathcal{H}_T - \mathcal{L}_T & \mathcal{K}_T \end{bmatrix}.$$
(6)

Given that the true distribution of disturbances is unknown, we focus on minimizing the *worst-case* mean-squared error (MSE) across all distributions within the ambiguity set $\mathscr{W}_T(\mathbb{P}^\circ_T, \rho_T)$, namely,

$$\mathsf{E}_{T}(\mathcal{K}_{T},\rho_{T}) \triangleq \sup_{\mathbb{P}_{T}\in\mathscr{W}_{T}(\mathbb{P}_{T}^{\circ},\rho_{T})} \mathbb{E}_{\mathbb{P}_{T}}\left[\|\mathbf{e}_{T}(\boldsymbol{\xi}_{T},\mathcal{K}_{T})\|^{2}\right].$$
(7)

where $\mathbb{E}_{\mathbb{P}_T}$ denotes the expectation under the distribution \mathbb{P}_T . We state the distributionally robust Kalman filtering problem for the finite-horizon setting as follows:

Problem 2.3 (W₂-DR-KF over a finite-horizon). For a given time-horizon T > 0 and a radius $\rho_T > 0$, find a casual filtering policy, $\mathcal{K}_T \in \mathcal{K}_T$, that minimizes the worst-case MSE defined in (7), *i.e.*,

$$\inf_{\mathcal{K}_T \in \mathscr{K}_T} \mathsf{E}_T(\mathcal{K}_T, \rho_T) = \inf_{\mathcal{K}_T \in \mathscr{K}_T} \sup_{\mathbb{P}_T \in \mathscr{W}_T(\mathbb{P}^\circ_T, \rho_T)} \mathbb{E}_{\mathbb{P}_T} \left[\| \mathbf{e}_T(\boldsymbol{\xi}_T, \mathcal{K}_T) \|^2 \right].$$
(8)

Remark 2.4. The causality constraint on the estimates \hat{s}_T is crucial for filtering. Without causality enforced, Problem 2.3 essentially reduces to a standard estimation problem as the nominal non-causal estimator is optimal for any $\rho_T > 0$ (Lemma 3.3).

2.2 The Infinite-Horizon Distributionally Robust Filtering

Designing optimal filters for extended horizons can generally be impractical extended time horizons. To mitigate this, time-invariant steady-state filters are usually deployed for practical purposes. These filters can be characterized by their Markov parameters $\{\hat{K}_t\}$, allowing the estimates $\{\hat{s}_t\}$ to be computed as a convolution sum: $\hat{s}_t = \sum_{s=0}^t \hat{K}_{t-s} y_s$. This can be expressed compactly as $\hat{s} = \mathcal{K} y$, where \mathcal{K} is a bounded, causal, and doubly-infinite block Toeplitz operator constructed from the Markov parameters \hat{K}_t . We denote the class of all such filtering policies by \mathcal{K} .

Here, y and \hat{s} are the doubly infinite column vectors of measurements and estimates, respectively. Furthermore, letting by $\boldsymbol{\xi} = [\mathbf{w}; \mathbf{v}]$, and s be doubly-infinite disturbance and target signal vectors, respectively, the state-space dynamics (2) over an infinite-horizon can then be described as follows:

where \mathcal{H} and \mathcal{L} are strictly causal, doubly-infinite, block Toeplitz operators, completely described by the state-space parameters (A, B, C_y, C_s) . The error transfer operator $\mathcal{T}_{\mathcal{K}} : \boldsymbol{\xi} \mapsto \mathbf{e} := \hat{\mathbf{s}} - \mathbf{s}$ under a stationary causal filtering policy $\mathcal{K} \in \mathcal{K}$ is defined similarly as $\mathcal{T}_{\mathcal{K}} := [\mathcal{K}\mathcal{H} - \mathcal{L} \quad \mathcal{K}]$. Note that these Toeplitz operators are equivalently identified by transfer function formalism. In particular, we have $\mathcal{H} \leftrightarrow \mathcal{H}(z) := C_y(zI - A)^{-1}B$ and $\mathcal{L} \leftrightarrow L(z) := C_s(zI - A)^{-1}B$ for $z \in \mathbb{T}$.

Instead of focusing on a fixed horizon, we consider the time-averaged steady-state worst-case MSE as the horizon approaches infinity, *i.e.*,

$$\overline{\mathsf{E}}(\mathcal{K},\rho) \triangleq \limsup_{T \to \infty} \frac{1}{T} \mathsf{E}_{T}(\mathcal{K},\rho_{T}) = \limsup_{T \to \infty} \frac{1}{T} \sup_{\mathbb{P}_{T} \in \mathscr{W}_{T}(\mathbb{P}^{\circ}_{\sigma},\rho_{T})} \mathbb{E}_{\mathbb{P}_{T}} \left[\|\mathbf{e}_{T}(\boldsymbol{\xi}_{T},\mathcal{K})\|^{2} \right].$$
(10)

The limit above may generally be infinite without further specification of the asymptotics of the ambiguity set. To ensure the finiteness of the steady-state MSE, we make the following assumptions: **Assumption 2.5.** The nominal disturbances $\{(w_t^{\circ}, v_t^{\circ})\}$ form a zero-mean weakly stationary random process, *i.e.*, the cross covariance between $(w_t^{\circ}, v_t^{\circ})$ and $(w_t^{\circ}, v_t^{\circ})$ only depends on the difference t-s. Furthermore, the size of the ambiguity set for horizon T > 0 scales as $\rho_T \sim \rho \sqrt{T}$ for a $\rho > 0$.

The assumption on the radius ρ_T for varying T is justified, as the total energy of a random vector of length T from a weakly stationary process scales linearly with T. We state the distributionally robust filtering problem for the infinite horizon as follows:

Problem 2.6 (W₂-DR-KF over infinite-horizon). Find a casual and time-invariant filter, $\mathcal{K} \in \mathcal{K}$, that minimizes the steady-state worst-case MSE defined in (10), *i.e.*,

$$\inf_{\mathcal{K}\in\mathscr{H}} \overline{\mathsf{E}}(\mathcal{K},\rho) = \inf_{\mathcal{K}\in\mathscr{H}} \limsup_{T\to\infty} \frac{1}{T} \sup_{\mathbb{P}_T\in\mathscr{W}_T(\mathbb{P}^\circ_T,\rho_T)} \mathbb{E}_{\mathbb{P}_T} \left[\|\mathbf{e}_T(\boldsymbol{\xi}_T,\mathcal{K})\|^2 \right].$$
(11)

3 Tractable Convex Formulations

In this section, we provide tractable formulations for the finite and infinite-horizon W_2 -DR-KF problems. In Theorem 3.4, we present an SDP formulation for the finite-horizon problem 2.3. In Theorem 3.8, we reduce the infinite-horizon problem 2.6 to a tractable convex program via duality. We also characterize the optimal estimator and the worst-case distribution for both settings. The proofs of the theorems presented in this section are deferred to the Appendix.

Before proceeding with the main theorems, we present a minimax theorem establishing the optimality of linear filtering policies for Gaussian nominal distributions.

Theorem 3.1 (Minimax duality). Let T > 0 be a fixed horizon and Π_T be the class of non-linear causal estimators. Suppose that the nominal \mathbb{P}°_T is Gaussian. Then, the following holds:

$$\inf_{\pi_T \in \Pi_T} \sup_{\mathbb{P}_T \in \mathscr{W}_T(\mathbb{P}^\circ_T, \rho_T)} \mathbb{E}_{\mathbb{P}_T} \left[\| \mathbf{e}_T(\boldsymbol{\xi}_T, \pi_T) \|^2 \right] = \sup_{\mathbb{P}_T \in \mathscr{W}_T(\mathbb{P}^\circ_T, \rho_T)} \inf_{\pi_T \in \Pi_T} \mathbb{E}_{\mathbb{P}_T} \left[\| \mathbf{e}_T(\boldsymbol{\xi}_T, \pi_T) \|^2 \right],$$
(12)

Moreover, (12) admits a saddle point $(\pi_T^{\star}, \mathbb{P}_T^{\star})$ such that the worst-case distribution \mathbb{P}_T^{\star} is Gaussian and the optimal causal filter π_T^{\star} is linear, i.e., $\pi_T^{\star} \in \mathscr{K}_T$.

For simplicity and clarity, we make the following assumption for the remainder of this paper. Assumption 3.2. The nominal disturbances are uncorrelated, *i.e.*, $\mathbb{E}_{\mathbb{P}_T^{\circ}}[\boldsymbol{\xi}_T \boldsymbol{\xi}_T^*] = \mathcal{I}_T$ for any T > 0.

3.1 An SDP for the Finite-Horizon Filtering

In this section, we state the SDP formulation of Problem 2.3 for a fixed horizon T > 0. To this end, we first state the following lemma identifying the optimal non-causal estimator.

Lemma 3.3. Under the Assumption 3.2, $\mathcal{K}_T^{\circ} \triangleq \mathcal{L}_T \mathcal{H}_T^* (\mathcal{I}_T + \mathcal{H}_T \mathcal{H}_T^*)^{-1}$ is the unique, optimal, non-causal estimator minimizing the worst-case MSE in (7) for any $\rho_T \ge 0$.

This result highlights the triviality of non-causal estimation as opposed to causal estimation. In Theorem 3.4, we demonstrate that the finite-horizon W_2 -DR-KF problem 2.3 reduces to an SDP.

Theorem 3.4 (An SDP formulation for finite-horizon W₂-DR-KF). Let the horizon T > 0 be fixed and denote $\mathcal{T}_{\mathcal{K}^{\circ}_{T}}\mathcal{T}^{*}_{\mathcal{K}^{\circ}_{T}} \coloneqq \mathcal{L}_{T}(\mathcal{I}_{T} + \mathcal{H}^{*}_{T}\mathcal{H}_{T})^{-1}\mathcal{L}^{*}_{T}$. Then, the Problem 2.3 reduces to the following SDP

$$\inf_{\substack{\mathcal{K}_T \in \mathscr{K}_T, \\ \gamma \geq 0, \, \mathcal{X}_T \in \mathbb{S}_+^{T_{\mathsf{d}_s}}}} \gamma(\rho_T^2 - \operatorname{Tr}(\mathcal{I}_T)) + \operatorname{Tr}(\mathcal{X}_T) \quad \text{s.t.} \quad \begin{bmatrix} \mathcal{X}_T & \gamma \mathcal{I}_T & 0\\ \gamma \mathcal{I}_T & \gamma \mathcal{I}_T - \mathcal{T}_{\mathcal{K}_T^\circ} \mathcal{T}_{\mathcal{K}_T^\circ}^* & \mathcal{K}_T - \mathcal{K}_T^\circ\\ 0 & (\mathcal{K}_T - \mathcal{K}_T^\circ)^* & (\mathcal{I}_T + \mathcal{H}_T \mathcal{H}_T^*)^{-1} \end{bmatrix} \succcurlyeq 0.$$

Moreover, the worst-case disturbance ξ_T^* *can be identified from the nominal disturbances* ξ_T^o *as*

$$\boldsymbol{\xi}_T^{\star} = (\mathcal{I}_T - \gamma_{\star}^{-1} \mathcal{T}_{\mathcal{K}_T^{\star}}^* \mathcal{T}_{\mathcal{K}_T^{\star}})^{-1} \boldsymbol{\xi}_T^{\circ}, \tag{13}$$

where $\gamma_{\star} > 0$ and \mathcal{K}_{T}^{\star} are the optimal solutions.

Remark 3.5. As $\rho_T \to \infty$, the ambiguity set covers all bounded energy disturbances, and the optimal W₂-DR-KF policy, \mathcal{K}_T^* , recovers the H_∞ -filter. Conversely, as $\rho_T \to 0$, the ambiguity set reduces to the singleton \mathbb{P}_T° , and \mathcal{K}_T^* recovers the Kalman filter. Thus, adjusting ρ_T allows the DR filter to interpolate between the conservative H_∞ -filter and the nominal Kalman filter.

Notice that the variable dimension of the SDP in Theorem 3.4 scales with the horizon T, which can be prohibitive for practical implementation for longer horizons.

Corollary 3.6. The time complexity of interior-point method for solving the SDP in Theorem 3.4 with accuracy $\epsilon > 0$ is $\widetilde{O}(\max(\mathsf{d}_u, \mathsf{d}_s)^6 T^6 \log(1/\epsilon))$.

3.2 A Concave-Convex Optimization for the Infinite-Horizon Filtering

The scaling of the SDP in Theorem 3.4 with the time horizon is prohibitive for many time-critical real-world applications. Therefore, we shift our focus to the infinite-horizon W_2 -DR-KF problem 2.6 to derive the optimal steady-state filtering policy.

Solving Problem 2.6 involves two major challenges. The first one is transforming the steady-state worst-case MSE for a fixed filtering policy $\mathcal{K} \in \mathscr{K}$, as defined in (10), to an equivalent convex optimization problem. We address this by leveraging the asymptotic convergence properties of Toeplitz matrices [73]. The second challenge is addressing the causality constraint on the estimator. To illustrate the triviality of non-causal estimation in the infinite-horizon setting, we present an analogous result as shown below:

Lemma 3.7. Under the Assumptions 2.5 and 3.2, $\mathcal{K}_{\circ} \coloneqq \mathcal{LH}^*(\mathcal{I} + \mathcal{HH}^*)^{-1}$ is the unique, optimal, non-causal estimator minimizing the steady-state worst-case MSE in (10) for any $\rho > 0$.

We address the causality constraint by reformulating Problem 2.6 as a max-min optimization, where the inner minimization over the causal filtering policies is performed using the Wiener-Hopf technique [86, 85] (see Lemma D.2). To this end, we introduce the *canonical spectral factorization*¹

$$\Delta \Delta^* = \mathcal{I} \! + \! \mathcal{H} \mathcal{H}^*$$

where both Δ and its inverse Δ^{-1} are causal operators. We state the equivalent formulation for the infinite-horizon W₂-DR-KF as follows.

Theorem 3.8 (Convex formulation of infinite-horizon W_2 -DR-KF). Under the Assumptions 2.5 and 3.2, the Problem 2.6 is equivalent to the following feasible max-min problem:

$$\sup_{\mathcal{M} \succ 0} \inf_{\mathcal{K} \in \mathscr{K}} \operatorname{Tr}(\mathcal{T}_{\mathcal{K}} \mathcal{T}_{\mathcal{K}}^* \mathcal{M}) \quad \text{s.t.} \quad \operatorname{Tr}(\mathcal{M} - 2\sqrt{\mathcal{M}} + \mathcal{I}) \le \rho^2.$$
(14)

¹Essentially Cholesky factorization for Toeplitz operators.

Defining $\mathcal{K}_{H_2} := \{\mathcal{K}_{\circ}\Delta\}_+\Delta^{-1}$, the unique saddle point $(\mathcal{K}_{\star}, \mathcal{M}_{\star})$ of (14) satisfies the following:

$$\mathcal{K}_{\star} = \mathcal{K}_{H_2} + \mathcal{U}_{\star}^{-1} \left\{ \mathcal{U}_{\star} \{ \mathcal{K}_{\circ} \Delta \}_{-} \right\}_{+} \Delta^{-1}, \tag{15a}$$

$$\mathcal{M}_{\star} = (\mathcal{I} - \gamma_{\star}^{-1} \mathcal{T}_{\mathcal{K}_{\star}} \mathcal{T}_{\mathcal{K}_{\star}}^{*})^{-2}, \tag{15b}$$

where $\mathcal{U}_{\star}^*\mathcal{U}_{\star} = \mathcal{M}_{\star}$ is the canonical spectral factorization with causal \mathcal{U}_{\star} and \mathcal{U}_{\star}^{-1} , and $\gamma_{\star} > 0$ is the unique value satisfying the constraint with equality, i.e.,

$$\operatorname{Tr}\left[\left(\left(\mathcal{I}-\gamma_{\star}^{-1}\mathcal{T}_{\mathcal{K}_{\star}}\mathcal{T}_{\mathcal{K}_{\star}}^{*}\right)^{-1}-\mathcal{I}\right)^{2}\right]=\rho^{2}.$$
(16)

The optimal linear filter \mathcal{K}_{\star} , comprises the nominal Kalman (aka H_2) filter, \mathcal{K}_{H_2} and an additive correction term that accounts for the correlations within the disturbance process. The correction term is derived directly from the optimal solution \mathcal{M}_{\star} of (14) through spectral factorization.

As a result of devising infinite-horizon filters achieving finite optimal value in (14), we can deduce the boundedness of the steady-state error covariance.

Corollary 3.9. The steady-state error has bounded covariance under the optimal \mathcal{K}_{\star} in (15).

4 An Efficient Algorithm

While the standard Kalman and H_{∞} -filters allow for finite-order spate-space realizations derived via algebraic methods, the optimal \mathcal{K}_{\star} lacks such a realization since its transfer function $K_{\star}(z)$ is non-rational (Corollary 4.2) despite admitting a non-linear finite-dimensional parametrization (Lemma 4.1). Thus, we adopt a novel twofold approach to develop practical DR filters:

- We introduce an efficient algorithm to compute the optimal positive-definite operator M_{*} from (14). To address the challanges posed by its infinite-dimensional nature, we use the frequency-domain representation of M_{*} as the power spectral density M_{*}(z) > 0.
- 2. We develop a novel method to approximate the non-rational power spectral density $M_{\star}(z)$ in H_{∞} norm using positive rational functions through convex optimization. This rational approximation
 is then used to derive an approximate rational filter with state-space realization via (15).

To this end, we adopt the transfer-function formalism for the rest of this paper with the correspondences: $\mathcal{M} \leftrightarrow \mathcal{M}(z), \mathcal{U} \leftrightarrow \mathcal{U}(z), \mathcal{K} \leftrightarrow \mathcal{K}(z)$, and $\mathcal{T}_{\mathcal{K}} \leftrightarrow \mathcal{T}_{\mathcal{K}}(z)$ for $z \in \mathbb{T}$. The following lemma characterizes the optimal $M_{\star}(z)$, implying finite-dimensional parametrization.

Lemma 4.1. Let $f : (\gamma, \Gamma) \mapsto \mathcal{M}$ return the unique solution of the implicit equation over M(z),

$$M(z) = \gamma^{2} [\gamma I - U(z)^{-1} \Gamma (I - z\overline{A})^{-1} \overline{B} \, \overline{B}^{*} (I - z\overline{A})^{-*} \Gamma^{*} U(z)^{-*} + T_{K_{\circ}}(z) T_{K_{\circ}}(z)^{*}]^{-2}, \forall z \in \mathbb{T}$$
(17)

where $U(z)^*U(z) = M(z)$ is the unique spectral factorization and $(\overline{A}, \overline{B}, \overline{C})$ are obtained from state-space parameters (see Appendix E.2 and (113)). We have that $\mathcal{M}_* = f(\gamma_*, \Gamma_*)$ where

$$\Gamma_{\star} = \frac{1}{2\pi} \int_{-\pi}^{\pi} U_{\star}(\mathrm{e}^{j\omega}) \overline{C} (I - \mathrm{e}^{j\omega} \overline{A})^{-1} d\omega, \qquad (18)$$

and $\gamma_{\star} > 0$ is such that $\operatorname{Tr}(\mathcal{M}_{\star} - 2\sqrt{\mathcal{M}_{\star}} + \mathcal{I}) = \rho^2$,

As a consequence of Lemma 4.1, we deduce the non-rationally of the optimal W₂-DR-KF. **Corollary 4.2.** The spectral density $M_{\star}(z)$ and the transfer function $K_{\star}(z)$ are non-rational.

4.1 Iterative Optimization Methods in the Frequency-Domain

Despite being a concave program, the infinite-dimensional nature of (14) hinders the direct application of standard optimization tools. To address this, we leverage frequency-domain analysis via transfer functions, enabling the use of standard tools with appropriate modifications. Specifically, we employ the modification of a Frank-Wolfe method [87, 88]. Our framework is versatile and can be extended to alternative approaches, including projected gradient descent [89], and the fixed-point iteration method used in [73]. A detailed pseudocode Algorithm 1 is provided in Appendix E.1.

Frank-Wolfe: We define the following function and its (Gateaux) gradient [90]:

$$\Phi(\mathcal{M}) \triangleq \inf_{\mathcal{K} \in \mathscr{K}} \operatorname{Tr} \left(\mathcal{T}_{\mathcal{K}} \mathcal{T}_{\mathcal{K}}^* \mathcal{M} \right), \text{ and } \nabla \Phi(\mathcal{M}) = \mathcal{U}^{-1} \left\{ \mathcal{U} \mathcal{K}_{\circ} \Delta \right\}_{-}^{*} \left\{ \mathcal{U} \mathcal{K}_{\circ} \Delta \right\}_{-}^{*} \mathcal{U}^{-*} + \mathcal{T}_{\mathcal{K}_{\circ}} \mathcal{T}_{\mathcal{K}_{\circ}}^{*}.$$
(19)

where $\mathcal{U}^*\mathcal{U} = \mathcal{M}$ is the spectral factorization. Rather than solving the optimization in (14) directly, the Frank-Wolfe method solves a linearized subproblem in consecutive steps. Namely, given the k^{th} iterate \mathcal{M}_k , the next iterate \mathcal{M}_{k+1} is obtained via

$$\widetilde{\mathcal{M}}_{k} = \underset{\mathcal{M} \succeq I}{\operatorname{arg\,max}} \operatorname{Tr}\left(\nabla \Phi(\mathcal{M}_{k}) \mathcal{M}\right) \quad \text{s.t.} \quad \operatorname{Tr}(\mathcal{M} - 2\sqrt{\mathcal{M}} + \mathcal{I}) \le \rho^{2},$$
(20a)

$$\mathcal{M}_{k+1} = (1 - \eta_k)\mathcal{M}_k + \eta_k \widetilde{\mathcal{M}}_k, \tag{20b}$$

where $\eta_k \in [0, 1]$ is a step-size, commonly set as $\eta_k = \frac{2}{k+2}$ [88]. Letting $\mathcal{G}_k := \nabla \Phi(\mathcal{M}_k)$ be the gradient as in (19), Frank-Wolfe updates can be expressed equivalently using spectral densities as:

$$\widetilde{M}_{k}(z) = (I - \gamma_{k}^{-1}G_{k}(z))^{-2} \quad \text{and} \quad M_{k+1}(z) = (1 - \eta_{k})M_{k}(z) + \eta_{k}\widetilde{M}_{k}(z), \quad \forall z \in \mathbb{T}$$
(21)

where $\gamma_k > 0$ solves $\operatorname{Tr}\left[((I - \gamma_k^{-1} \mathcal{G}_k)^{-1} - I)^2\right] = \rho^2$. See Appendix E.4 for a closed-form $G_k(z)$.

Discretization: Instead of the continuous domain unit circle \mathbb{T} , we consider its uniform discretization by N points, $\mathbb{T}_N := \{e^{j2\pi n/N} \mid n = 0, ..., N-1\}$. While the gradient update $G_k(z)$ for frequency z is applied to the next iterate $M_{k+1}(z)$ at that frequency, calculating $G_k(z)$ requires $M_k(z')$ at all other frequencies $z' \in \mathbb{T}$ due to spectral factorization involved. Thus, the full update for $M_{k+1}(z)$ needs $M_k(z')$ across the entire unit circle. This is overcome by finer discretization.

Spectral Factorization: Since the iterates $M_k(z)$ are non-rational spectral densities, the spectral factorization can only be performed approximately [91]. Specifically, we employ the algorithm proposed in [92] that uses discrete Fourier transform (DFT) and is based on Kolmogorov's method of factorization [93]. This method, tailored for scalar spectral densities (*i.e.*, for scalar target signals $d_s = 1$), proves efficient as the associated error term, featuring a multiplicative phase factor, rapidly diminishes with finer discretization N. Matrix-valued spectral densities can also be tackled by various other algorithms [94, 95]. See Appendix E.5 for a pseudocode and details.

Bisection: We use bisection method to find the $\gamma_k > 0$ that solves $\text{Tr}\left[((I - \gamma_k^{-1}\mathcal{G}_k)^{-1} - I)^2\right] = \rho^2$ in the Frank-Wolfe update (21). See Appendix E.6 for a pseudocode and further details.

Remark 4.3. The gradient $G_k(z)$ requires computation of the finite-dimensional parameter via (18), which can be performed using N-point trapezoidal integration. See Appendix E.4 for details.

We conclude this section with the following convergence result due to [88, 96].

Theorem 4.4 (Convergence of \mathcal{M}_k). There exists constants $\delta_N > 0$, depending on discretization N, and $\kappa > 0$, depending only on state-space parameters (2) and ρ , such that the iterates in (20) satisfy

$$\Phi(\mathcal{M}_{\star}) - \Phi(\mathcal{M}_k) \le \frac{2\kappa}{k+2}(1+\delta_N).$$
(22)

4.2 Rational Approximation using H_{∞} -norm

In the preceding section, we introduced a method to compute the optimal $M_{\star}(z)$ approximately on the unit circle. However, the resulting filtering policy is non-rational and cannot be realized as a statespace filter. In this section, we introduce a novel technique for obtaining approximate rational filtering policies. Instead of directly approximating the filter itself, our method involves an initial step of *approximating the power spectrum* $M_{\star}(z)$ by a ratio of positive fixed order polynomials, P(z)/Q(z), to minimize the H_{∞} -norm of the approximation error. After finding a rational approximation P(z)/Q(z) of $M_{\star}(z)$, we compute a state-space controller according to Eq. (15). For simplicity, we focus on scalar target signals, namely, $d_s = 1$.

Concretely, $P(z) = \sum_{k=-m}^{m} p_k z^{-k}$ and $Q(z) = \sum_{k=-m}^{m} q_k z^{-k}$ are Laurent polynomials of degree $m \in \mathbb{N}$ with symmetric coefficients $p_k = p_{-k} \in \mathbb{R}$ and $q_k = q_{-k} \in \mathbb{R}$. In other words, the polynomials P(z) and Q(z) are uniquely identified by m + 1 real coefficients, (p_0, \ldots, p_m) and (q_0, \ldots, q_m) . Given a positive spectral density M(z) > 0 for $z \in \mathbb{T}$, we seek positive polynomials P(z), Q(z) > 0

for $z \in \mathbb{T}$ of order at most $m \in \mathbb{N}$ that minimize the H_{∞} -norm of the rational approximation error, *i.e.*,

$$i) P(z), Q(z) > 0 \text{ for all } z \in \mathbb{T},$$

$$ii) q_0 = 1,$$

$$iii) q_0 = 1,$$

$$iii) \max_{z \in \mathbb{T}} \left| \frac{P(z)}{Q(z)} - M(z) \right| \le \varepsilon,$$
(23)

where $\varepsilon \ge 0$ denotes an *upper bound on the approximation error*. The constraint $q_0 = 1$ eliminates redundancy in the problem since the fraction P(z)/Q(z) is scale invariant. Unfortunately, the problem (23) is not convex in all the variables. Instead, Lemma 4.5 shows convexity for fixed $\varepsilon \ge 0$.

Lemma 4.5. For a fixed $\varepsilon \ge 0$, the constraints (*i*-iii) define a jointly convex set for the coefficients.

Proof. The constraints (*i-ii*) are affine inequalities, hence convex. Constraint (*iii*) is equivalent to

$$P(z) - (M(z) + \varepsilon)Q(z) \le 0, \text{ and } P(z) - (M(z) - \varepsilon)Q(z) \ge 0, \text{ for all } z \in \mathbb{T},$$
(24)

which are jointly affine inequalities in $(p_0, \ldots p_m)$ and $(q_0, \ldots q_m)$, hence convex.

This result enables us to obtain m^{th} -order rational approximations P(z)/Q(z) of M(z) with a fixed approximation precision ε , signifying our tolerance for deviations from M(z), by solving a *convex feasibility problem*. Notice that the constraints (i) and (iii) (eqv. (24)) involve inequalities over the entire unit circle \mathbb{T} . Since the iterative method in Algorithm 1 only returns the values of M(z) on the discretized unit circle \mathbb{T}_N , we can enforce these inequalities in the feasibility problem only for \mathbb{T}_N . While being an inexact approximation for (*iii*), it is an exact characterization for (*i*) as long as N > 2m by the Nyquist-Shannon sampling theorem [97]. See Appendix E.8 for a pseudocode.

Utilizing a convex feasibility oracle, our method can be used in two operational modes:

- 1. Fixed order, best precision: By iteratively reducing the precision ε we can revise the ε -feasible polynomials P(z), Q(z), effectively solving the non-convex problem (23) to obtain the best m^{th} -order rational approximation.
- 2. Fixed precision, least order: In contrast, we can seek the lowest degree rational approximation, which achieves a fixed precision ε .

Theorem 4.6. The spectral factorization $U(z)^*U(z) = P(z)/Q(z)$ of a degree *m* rational approximation P(z)/Q(z) admits a rational factor U(z). Furthermore, the filter obtained from U(z) using (15), i.e., $K(z) = K_{H_2}(z) + U(z)^{-1} \{U(z)\{K_{\circ}(z)\Delta(z)\}_{-}\}_{+} \Delta(z)^{-1}$ is rational and can be realized as a state-space filter as highlighted below:

$$\begin{aligned} \zeta_{t+1} &= F\zeta_t + Gy_t, \\ \widehat{s}_t &= \widetilde{H}\zeta_t + \widetilde{L}y_t, \end{aligned} \tag{25}$$

where $\zeta_t \in \mathbb{R}^{m+d_x}$ is the filter state, and $(\widetilde{F}, \widetilde{G}, \widetilde{H}, \widetilde{L})$ are determined from (A, B, C_u, C_u) and U(z).

5 Numerical Experiments

In this section, we compare the performance of finite and infinite horizon DR-KF filters with H_2 , H_∞ filters, and other DRKFs [50], [55]. Our evaluation includes both frequency domain and time-domain analyses, highlighting the effectiveness of the rational approximation method. The nominal distribution is assumed to be Gaussian with zero mean and identity covariance. Our results demonstrate that our DR-KF (in the finite and ∞ horizon) provides significant advantages over other DRKFs in terms of stability, computational speed, and error reduction. The experiments were performed on a M1 Macbook Air with 8 GB of RAM.

5.1 Frequency Domain Evaluations

We study a typical tracking problem whose state-space model is $A = \begin{bmatrix} 1 & \Delta t \\ 0 & 1 \end{bmatrix}$, $B = \begin{bmatrix} 0 & \Delta t \end{bmatrix}^T$, $C_y = \begin{bmatrix} 1 & 0 \end{bmatrix} C_y$

 $\begin{bmatrix} 1 & 0 \end{bmatrix}$, $C_s = 1$ where the state corresponds to the position and velocity, the process noise is the exogenous acceleration, and Δt is the sampling time. We plot the frequency response of our DR-KF

using the metric $|T_K(e^{j\omega})|^2 = \sigma(T_K^*(e^{j\omega})T_K(e^{j\omega}))$, where σ is the maximal singular value. We compare it to the classical H_2 (KF) and H_∞ (robust) filters. Figure 1a shows that the DR-KF interpolates well between the H_2 (KF) and H_∞ (robust) filters. Figure 1b illustrates the worst-case expected MSE. For smaller r, the DR-KF performs similarly to the \mathcal{H}_2 (KF) filter, while for larger r, its worst-case MSE approaches that of the robust filter. Overall, the DR-KF achieves the lowest worst-case expected MSE for any r. We investigate the behavior of the rational approximation across various values of the radius r. The results for degrees m = 1, 2, 3 are given in Table 1. Approximations of order greater than 2 achieve an expected MSE closely matching the non-rational DR-KF for all values of r.

(a) Frequency response for the tracking problem.

(b) Worst-case expected MSE.

Figure 1: DR-KF versus the $\mathcal{H}_2, \mathcal{H}_\infty$ filters and the variation of the expected MSE with r.

	r=0.01	r=1	r=3	r=5
DRKF	0.7870	3.4948	14.842	34.110
RA(1)	0.7871	3.5818	15.954	38.327
RA(2)	0.7870	3.4948	14.844	34.124
RA(3)	0.7870	3.4948	14.834	34.024

Table 1: The worst-case expected MSE of the nonrational DRKF, compared to the rational filters RA(1), RA(2), and RA(3), obtained from degree 1, 2, and 3 rational approximations to $U(e^{j\omega})$, for the system in Section 5.1.

	T=10	T=50	T=100	T=1000
DRMC	32.9 s	NAN	NAN	NAN
Our DRKF (finite)	0.65 s	7.3 s	194.9 s	NAN
Our DRKF (infinite)	6.6 s	6.6 s	6.6 s	6.6 s

Table 2: The running time (in seconds) of different filters for the system in section 5.4. The DRMC is inefficient for T> 10, our DRKF (finite) is inefficient for T> 50 while our ∞ horizon DRKF can run for any horizon.

5.2 Time Domain Evaluations

We assess the time-domain performance of both infinite and finite horizon DR-KF filters, comparing them with H_2 and H_{∞} counterparts on the tracking problem introduced in Section 5.1. The average MSE over 50 time steps, aggregated across 1000 independent trials, is plotted. In Figure 2a, under white Gaussian noise, the H_2 (KF) filter outperforms others. Figures 2b and 2c correspond to correlated Gaussian noise and the worst-case noise for the finite horizon DRKF, respectively. In Figures 2b and 2c, the DRKF outperforms the classical filters, and the infinite horizon DRKF matches the finite horizon one. As we increase the time horizon, solving the finite horizon SDP becomes computationally infeasible, underscoring the advantage of the infinite horizon DRKF.

Figure 2: The average MSE of the different filters for the tracking problem, under (a) white noise, (b) correlated Gaussian noise, and (c) worst-case noise for the finite horizon DR KF for the system in Section 5.1. While the H_2 filter (KF) performs best in (a), it behaves poorly in (b), (c). The DRKF achieves the lowest error in (b) and (c), and the finite and infinite horizon achieve similar average MSE at the end of the horizon.

5.3 Comparison to the DRKF in [50]

We first compare against [50] which assumes the states and measurements to be in a Wasserstein neighborhood around a nominal at each time step, robustifying immediately against model uncertainties. Authors in [50] don't consider noise correlations across time steps, their problem setup is in the finite-horizon, and they use the Frank-Wolfe algorithm to efficiently solve the problem.

The system matrices that they consider is given by $A = \begin{bmatrix} 0.9802 & 0.0196 + 0.099\Delta \\ 0 & 0.9802 \end{bmatrix}$, $Q = \begin{bmatrix} 1.9608 & 0.0195 \\ 0.0195 & 1.9605 \end{bmatrix}$, $B = \begin{bmatrix} \sqrt{Q} & 0_{2\times 1} \end{bmatrix}$, $C_y = \begin{bmatrix} 1 & -1 \end{bmatrix}$, $C_s = I$, and Δ represents a scalar uncertainty (taken to be 1 as in [50]). We compare the performance of our infinite-horizon DRKF to [50] in Figure 3 under Gaussian noise. The plot shows that our DRKF outperforms [50] and has a more stable performance, even though we are disadvantaged in two ways: 1) our filter isn't explicitly

designed for model uncertainties, 2) since we only consider estimations of linear combination of the state (C_s is a row vector), we get the total MSE from 2 different runs with $C_s = \begin{bmatrix} 1 & 0 \end{bmatrix}$ and $C_s = \begin{bmatrix} 0 & 1 \end{bmatrix}$, which is suboptimal.

(a) Average MSE in dB under Gaussian noise.

Figure 3: Average MSE for the KF, our DRKF, and the DRKF from [50], for system in section 5.3.

5.4 Comparison to the DR estimator of [55]

We contrast our approach with that of [55], termed linear quadratic estimator under martingale constraints (DRMC). Here are the key comparisons: 1) DRMC, akin to our approach, considers noise within a Wasserstein neighborhood around a baseline, allowing for correlations between process and measurement noise (achieved through a martingale sequence constraint). 2) DRMC assumes the process noise is sampled from the baseline and doesn't lie in the Wasserstein ball, a more restrictive assumption compared to ours. 3) DRMC's problem formulation is in the finite-horizon, claiming to have an efficient converging method to solve it. With a horizon of T = 10, they test their approach on a simple 1D system ($A = B = C_y = C_s = 1$), which we also use for comparison. For $r = 0.2\sqrt{T}$ and under the worst-case noise for our finite-horizon DRKF, the average MSE for DRMC is 0.86, closely matching our finite-horizon DRKF at 0.86 and our infinite-horizon DRKF at 0.88 at T = 10. For the same r = under the worst-case noise of DRMC, the average MSE for DRMC is 0.78, close to our DRKF (0.81 for the finite-horizon and 0.83 for the infinite-horizon at T = 10). This shows that using the infinite-horizon controller for short horizons does not significantly compromise performance. Similar results are observed for other values of r. While the performances in this simple example are comparable, our filter is anticipated to excel for higher-diemsnional systems, due to its explicit consideration of robustness over process noise. However, our DRKFs outshine DRMC in efficiency. DRMC takes 32.9 seconds for T = 10, and becomes computationally infeasible beyond that. Our finite-horizon DRKF is faster and efficient up to T = 50, and our infinite-horizon DRKF remains unaffected by the time horizon. For details, see Table 2.

6 Conclusion

The main limitation in our work is that our H_{∞} -rational approximation method is limited to scalar target signals (*i.e.*, C_s is a row vector). Future work will address this limitation.

A Simulation Results

A.1 Another tracking problem

We study another tracking problem, standard in the filtering community, whose state-space model is

$$F = \begin{bmatrix} 1 & 0 & 0 & 0 \\ \Delta t & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & \Delta t & 1 \end{bmatrix}, G = \begin{bmatrix} \Delta t & 0 \\ 0.5(\Delta t)^2 & 0 \\ 0 & \Delta t \\ 0 & 0.5(\Delta t)^2 \end{bmatrix}, H = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, L = \begin{bmatrix} 0 & 0 & 0 & 1 \end{bmatrix},$$

with $\Delta t = 1$. The results are shown in the plots below.

Figure 4: The frequency response of different filters (\mathcal{H}_2 , \mathcal{H}_∞ and DRKF) for the tracking problem in section A. The worst-case expected MSE is 3.99 for H_∞ , 3.77 for H_2 and 3.47 (lowest) for DRKF.

Figure 5: The average MSE of the different filters horizon under different disturbances for the tracking problem in section A. (a) is white noise, while (b) is the worst-case noise for the finite horizon DR KF (SDP). While the KF performs best under gaussian noise, the DRKF achieves the lowest error in most of other scenarios (including the more realistic case of correlated noise), and the finite and infinite horizon achieve similar avergae MSE at the end of the horizon.

B Additional Discussion on the Problem Setup

B.1 Explicit Form of Finite-Horizon Model in (3)

The causal linear measurement model for the finite-horizon case in (3) can be stated explicitly as follows:

$$\begin{bmatrix} y_{0} \\ y_{1} \\ y_{2} \\ \vdots \\ y_{T} \end{bmatrix} = \underbrace{\begin{bmatrix} C_{y} & 0 & 0 & \cdots & 0 \\ C_{y}A & C_{y}B & 0 & \cdots & 0 \\ C_{y}A^{2} & C_{y}AB & C_{y}B & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ C_{y}A^{T} & C_{y}A^{T-1}B & C_{y}A^{T-2}B & \ddots & C_{y}B \end{bmatrix}}_{\mathcal{H}_{T}} \begin{bmatrix} x_{0} \\ w_{0} \\ w_{1} \\ \vdots \\ w_{T-1} \end{bmatrix} + \underbrace{\begin{bmatrix} v_{0} \\ v_{0} \\ v_{1} \\ \vdots \\ w_{T} \end{bmatrix}}_{\mathbf{v}}$$
(26a)
$$\underbrace{\begin{bmatrix} s_{0} \\ s_{1} \\ s_{2} \\ \vdots \\ s_{T} \end{bmatrix}}_{\mathbf{s}} = \underbrace{\begin{bmatrix} C_{s} & 0 & 0 & \cdots & 0 \\ C_{s}A & C_{s}B & 0 & \cdots & 0 \\ C_{s}A^{2} & C_{s}AB & C_{s}B & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ C_{s}A^{T} & C_{s}A^{T-1}B & C_{s}A^{T-2}B & \ddots & C_{s}B \end{bmatrix}}_{\mathcal{L}_{T}} \underbrace{\begin{bmatrix} x_{0} \\ w_{0} \\ w_{1} \\ \vdots \\ w_{T-1} \end{bmatrix}}_{\mathbf{w}}$$
(26b)

A similar construction of \mathcal{H}_T and \mathcal{L}_T for time-varying systems can be performed by replacing the causal block elements of \mathcal{H}_T and \mathcal{L}_T with appropriate coefficients derived from the time-varying dynamics.

C Proofs of Theorems Related to Finite-Horizon Filtering

C.1 Proof of Theorem 3.1

Before we proceed with the proof, we first state the following useful deifnitions and results.

Definition C.1 (Bures-Wasserstein distance [98]). For any two psd matrices $\Sigma_1, \Sigma_2 \in \mathbb{S}^d_+$, the Bures-Wasserstein distance between them is defined as follows:

$$\mathsf{BW}(\Sigma_1, \Sigma_2) \triangleq \sqrt{\mathrm{Tr}\left[\Sigma_1 + \Sigma_2 - 2\left(\Sigma_1^{1/2}\Sigma_2\Sigma_1^{1/2}\right)^{1/2}\right]}.$$
(27)

Definition C.2 (Gelbrich distance [99]). For any two distributions $\mathbb{P}_1, \mathbb{P}_2 \in \mathscr{P}(\mathbb{R}^d)$ with means $\mu_1, \mu_2 \in \mathbb{R}^d$ and covariances $\Sigma_1, \Sigma_2 \in \mathbb{S}^d_+$, respectively, the Gelbrich distance between them is defined as follows:

$$\mathsf{G}(\mathbb{P}_1, \mathbb{P}_2) \triangleq \sqrt{\|\mu_1 - \mu_2\|^2 + \mathsf{BW}(\Sigma_1, \Sigma_2)^2}.$$
(28)

Lemma C.3 (Gelbrich bound [99, Thm. 2.1]). Consider two distributions $\mathbb{P}_1, \mathbb{P}_2 \in \mathscr{P}(\mathbb{R}^d)$ with means $\mu_1, \mu_2 \in \mathbb{R}^d$ and covariances $\Sigma_1, \Sigma_2 \in \mathbb{S}^d_+$, respectively. The W₂-distance between them satisfies

$$\mathsf{W}_2(\mathbb{P}_1, \mathbb{P}_2) \ge \mathsf{G}(\mathbb{P}_1, \mathbb{P}_2),\tag{29}$$

where equality is attained if both \mathbb{P}_1 and \mathbb{P}_2 are Gaussian distributions.

Lemma C.4 (Causal MMSE of Gaussian [85]). Suppose the disturbances are distributed as Gaussian, *i.e.*, $\boldsymbol{\xi}_T \sim \mathcal{N}(\boldsymbol{\mu}_T, \boldsymbol{\Sigma}_T)$ with mean $\boldsymbol{\mu}_T \in \Xi_T$ and covariance $\boldsymbol{\Sigma}_T$. Consider causal mean-square estimation of \mathbf{s}_T from \mathbf{y}_t , *i.e.*,

$$\inf_{\pi_T \in \Pi_T} \mathbb{E}\left[\|\mathbf{e}_T(\boldsymbol{\xi}_T, \pi_T)\|^2 \right].$$
(30)

Then, there exists a causal (block lower-diagonal) matrix \mathcal{K}_T^* and a vector \mathbf{b}_T^* , such that the optimal causal estimator $\pi_T^* : \mathbf{y}_T \mapsto \widehat{\mathbf{s}}_T$ is affine with the following form:

$$\widehat{\mathbf{s}}_T = \mathcal{K}_T^\star \mathbf{y}_t + \mathbf{b}_T^\star. \tag{31}$$

Proof of Theorem 3.1: Clearly, we have the following weak duality,

(

$$\sup_{\mathbb{P}_T \in \mathscr{W}_T(\mathbb{P}^\circ_T, \rho_T)} \inf_{\pi_T \in \Pi_T} \mathbb{E}_{\mathbb{P}_T} \left[\| \mathbf{e}_T(\boldsymbol{\xi}_T, \pi_T) \|^2 \right] \le \inf_{\pi_T \in \Pi_T} \sup_{\mathbb{P}_T \in \mathscr{W}_T(\mathbb{P}^\circ_T, \rho_T)} \mathbb{E}_{\mathbb{P}_T} \left[\| \mathbf{e}_T(\boldsymbol{\xi}_T, \pi_T) \|^2 \right].$$
(32)

Let $\Sigma_T^{\circ} \succ 0$ be the covariance of the nominal distribution \mathbb{P}_T° . We start by bounding the lhs of (32) as follows:

$$\sup_{\mathbb{P}_T \in \mathscr{W}_T(\mathbb{P}_T^\circ, \rho_T)} \inf_{\pi_T \in \Pi_T} \mathbb{E}_{\mathbb{P}_T} \left[\| \mathbf{e}_T(\boldsymbol{\xi}_T, \pi_T) \|^2 \right] \stackrel{(a)}{\leq} \sup_{\mathsf{G}(\mathbb{P}_T, \mathbb{P}_T^\circ) \leq \rho_T} \inf_{\pi_T \in \Pi_T} \mathbb{E}_{\mathbb{P}_T} \left[\| \mathbf{e}_T(\boldsymbol{\xi}_T, \pi_T) \|^2 \right], \quad (33)$$

$$\stackrel{(b)}{\leq} \sup_{\mathbf{G}(\mathbb{P}_T, \mathbb{P}_T^{\circ}) \leq \rho_T} \inf_{\mathcal{K}_T \in \mathscr{K}_T} \mathbb{E}_{\mathbb{P}_T} \left[\| \mathbf{e}_T(\boldsymbol{\xi}_T, \mathcal{K}_T) \|^2 \right],$$
(34)

$$= \sup_{\mathsf{G}(\mathbb{P}_{T},\mathbb{P}_{T}^{\circ}) \leq \rho_{T}} \inf_{\mathcal{K}_{T} \in \mathscr{K}_{T}} \mathbb{E}_{\mathbb{P}_{T}} \left[\boldsymbol{\xi}_{T}^{*} \mathcal{T}_{\mathcal{K}_{T}}^{*} \mathcal{T}_{\mathcal{K}_{T}} \boldsymbol{\xi}_{T} \right],$$
(35)

$$\stackrel{(c)}{=} \sup_{\mathsf{G}(\mathbb{P}_T,\mathbb{P}^\circ_T) \le \rho_T} \inf_{\mathcal{K}_T \in \mathscr{K}_T} \operatorname{Tr} \left(\mathcal{T}^*_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T} \mathbb{E}_{\mathbb{P}_T} \left[\boldsymbol{\xi}_T \boldsymbol{\xi}_T^* \right] \right), \tag{36}$$

$$\stackrel{d)}{=} \sup_{\mathsf{BW}(\boldsymbol{\Sigma}_T, \boldsymbol{\Sigma}_T^\circ) \le \rho_T} \inf_{\mathcal{K}_T \in \mathscr{K}_T} \operatorname{Tr} \left(\mathcal{T}_{\mathcal{K}_T}^* \mathcal{T}_{\mathcal{K}_T} \boldsymbol{\Sigma}_T \right),$$
(37)

where (a) follows from the Gelbrich bound (Lemma C.3), (b) follows from $\mathcal{K}_T \subset \Pi_T$, (c) follows from linearity of cyclic property of trace and the linearity of trace and the expectation, (d) follows from the definition of the Gelbrich distance (Definition C.2). Note that, we can in general take the distributions involved to be zero-mean since any non-zero mean can be incorporated as an additive constant to the estimator, canceling the mean. Therefore, without loss of generality, we can restrict ourselves to zero-mean disturbances and linear estimators (instead of affine).

Following a similar reasoning, we obtain the following upper bound on the rhs of (32),

$$\inf_{\pi_T \in \Pi_T} \sup_{\mathbb{P}_T \in \mathscr{W}_T(\mathbb{P}^\circ_T, \rho_T)} \mathbb{E}_{\mathbb{P}_T} \left[\| \mathbf{e}_T(\boldsymbol{\xi}_T, \pi_T) \|^2 \right] \le \inf_{\mathcal{K}_T \in \mathscr{K}_T} \sup_{\mathsf{BW}(\boldsymbol{\Sigma}_T, \boldsymbol{\Sigma}^\circ_T) \le \rho_T} \operatorname{Tr} \left(\mathcal{T}^*_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T} \boldsymbol{\Sigma}_T \right).$$
(38)

Notice that the objective in the right-hand side of (38) is affine in Σ_T (hence concave) and quadratic in \mathcal{K}_T (hence strictly convex whenever $\Sigma_T \succ 0$). Furthermore, the constraint set \mathscr{K}_T is affine, and the constraint BW(Σ_T, Σ_T°) is convex [98]. Therefore, we have the following minimax duality.

$$\inf_{\mathcal{K}_T \in \mathscr{K}_T} \sup_{\mathsf{BW}(\boldsymbol{\Sigma}_T, \boldsymbol{\Sigma}_T^{\circ}) \le \rho_T} \operatorname{Tr} \left(\mathcal{T}_{\mathcal{K}_T}^* \mathcal{T}_{\mathcal{K}_T} \boldsymbol{\Sigma}_T \right) = \sup_{\mathsf{BW}(\boldsymbol{\Sigma}_T, \boldsymbol{\Sigma}_T^{\circ}) \le \rho_T} \inf_{\mathcal{K}_T \in \mathscr{K}_T} \operatorname{Tr} \left(\mathcal{T}_{\mathcal{K}_T}^* \mathcal{T}_{\mathcal{K}_T} \boldsymbol{\Sigma}_T \right).$$
(39)

We denote the saddle point of (39) by $(\mathcal{K}_T^{\star}, \Sigma_T^{\star})$. Notice that, when the nominal distribution is Gaussian $\mathbb{P}_T^{\circ} \coloneqq \mathcal{N}(0, \Sigma_T^{\circ})$, the Gaussian distribution $\mathbb{P}_T^{\star} \coloneqq \mathcal{N}(0, \Sigma_T^{\star})$ and the causal estimator $\pi_T^{\star} \coloneqq \mathcal{K}_T^{\star}$ achieve the upper bound (37) with equality. Thus, from (32) and (38), we obtain the desired result.

C.2 Proof of Lemma 3.3

Before we proceed with the proof, we state the following result, which is the backbone for both Theorem 3.4 and Theorem 3.8.

Theorem C.5 (Strong Duality in the Finite Horizon). Let the horizon T > 0 be fixed and \mathcal{K}_T be a given estimator, which can be non-causal in general. Under the Assumption 3.2, the finite-horizon worst-case MSE (7) suffered by \mathcal{K}_T , i.e.,

$$\mathsf{E}_{T}(\mathcal{K}_{T},\rho_{T}) = \sup_{\mathbb{P}_{T}\in\mathscr{W}_{T}(\mathbb{P}_{T}^{\circ},\rho_{T})} \mathbb{E}_{\mathbb{P}_{T}}\left[\boldsymbol{\xi}_{T}^{*}\mathcal{T}_{\mathcal{K}_{T}}^{*}\mathcal{T}_{\mathcal{K}_{T}}\boldsymbol{\xi}_{T}\right],\tag{40}$$

attains a finite value and is equivalent to the following dual problem:

$$\mathsf{E}_{T}(\mathcal{K}_{T},\rho_{T}) = \inf_{\gamma \geq 0} \gamma \rho_{T}^{2} + \gamma \operatorname{Tr}\left[(\mathcal{I}_{T} - \gamma^{-1} \mathcal{T}_{\mathcal{K}_{T}} \mathcal{T}_{\mathcal{K}_{T}}^{*})^{-1} - \mathcal{I}_{T} \right] \quad s.t. \quad \gamma \mathcal{I}_{T} \succ \mathcal{T}_{\mathcal{K}_{T}} \mathcal{T}_{\mathcal{K}_{T}}^{*}.$$
(41)

Furthermore, the worst-case disturbance, ξ_T^* , can be identified from the nominal disturbance, ξ_T° , as

$$\boldsymbol{\xi}_T^{\star} = (\mathcal{I}_T - \gamma_{\star}^{-1} \mathcal{T}_{\mathcal{K}_T}^* \mathcal{T}_{\mathcal{K}_T})^{-1} \boldsymbol{\xi}_T^{\circ}, \tag{42}$$

where γ_{\star} is the optimal solution of (41) and solves the following equation uniquely:

$$\operatorname{Tr}\left[\left(\left(\mathcal{I}_{T}-\gamma_{\star}^{-1}\mathcal{T}_{\mathcal{K}_{T}}\mathcal{T}_{\mathcal{K}_{T}}^{*}\right)^{-1}-\mathcal{I}_{T}\right)^{2}\right]=\rho_{T}^{2}.$$
(43)

Proof. The proof follows closely from [68, Thm. 2 & 3] (and also from [72, Thm. IV.1]) by replacing the matrix C in Thm.2 of [68] with $\mathcal{T}_{\mathcal{K}_T}^*\mathcal{T}_{\mathcal{K}_T}$. In that case, we get that

$$\mathsf{E}_{T}(\mathcal{K}_{T},\rho_{T}) = \inf_{\gamma \geq 0} \gamma \rho_{T}^{2} + \gamma \operatorname{Tr}\left[(\mathcal{I}_{T} - \gamma^{-1} \mathcal{T}_{\mathcal{K}_{T}}^{*} \mathcal{T}_{\mathcal{K}_{T}})^{-1} - \mathcal{I}_{T} \right] \quad \text{s.t.} \quad \gamma \mathcal{I}_{T} \succ \mathcal{T}_{\mathcal{K}_{T}}^{*} \mathcal{T}_{\mathcal{K}_{T}}, \quad (44)$$

and the characterization of the optimal solution $\gamma_{\star} \geq 0$ as

$$\operatorname{Tr}\left[\left(\left(\mathcal{I}_{T}-\gamma_{\star}^{-1}\mathcal{T}_{\mathcal{K}_{T}}^{*}\mathcal{T}_{\mathcal{K}_{T}}\right)^{-1}-\mathcal{I}_{T}\right)^{2}\right]=\rho_{T}^{2}.$$
(45)

Notice that (44) and (45) involve the term $\mathcal{T}_{\mathcal{K}_T}^* \mathcal{T}_{\mathcal{K}_T}$ whereas the desired formulations in (41) and (43) involve the term $\mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^*$. To obtain the desired formulations, we appeal to matrix inversion identity, *i.e.*,

$$(\mathcal{I}_T - \gamma^{-1} \mathcal{T}^*_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T})^{-1} = \mathcal{I}_T + \mathcal{T}^*_{\mathcal{K}_T} (\gamma \mathcal{I}_T - \mathcal{T}_{\mathcal{K}_T} \mathcal{T}^*_{\mathcal{K}_T})^{-1} \mathcal{T}_{\mathcal{K}_T},$$
(46)

$$= \mathcal{I}_T + \gamma^{-1} \mathcal{T}_{\mathcal{K}_T}^* (\mathcal{I}_T - \gamma^{-1} \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^*)^{-1} \mathcal{T}_{\mathcal{K}_T},$$
(47)

where the exact block dimensions of the identity operator \mathcal{I}_T differ depending on where they appear and should be inferred from the context. We can evaluate the trace in (44) involving $\mathcal{T}_{\mathcal{K}_T}^* \mathcal{T}_{\mathcal{K}_T}$ as

$$\operatorname{Tr}\left[\left(\mathcal{I}_{T}-\gamma^{-1}\mathcal{T}_{\mathcal{K}_{T}}^{*}\mathcal{T}_{\mathcal{K}_{T}}\right)^{-1}-\mathcal{I}_{T}\right]=\operatorname{Tr}\left[\mathcal{I}_{T}+\gamma^{-1}\mathcal{T}_{\mathcal{K}_{T}}^{*}(\mathcal{I}_{T}-\gamma^{-1}\mathcal{T}_{\mathcal{K}_{T}}\mathcal{T}_{\mathcal{K}_{T}}^{*})^{-1}\mathcal{T}_{\mathcal{K}_{T}}-\mathcal{I}_{T}\right],\quad(48)$$
$$=\operatorname{Tr}\left[\gamma^{-1}\mathcal{T}_{\mathcal{K}}^{*}\left(\mathcal{I}_{T}-\gamma^{-1}\mathcal{T}_{\mathcal{K}_{T}}\mathcal{T}_{\mathcal{K}}^{*}\right)^{-1}\mathcal{T}_{\mathcal{K}_{T}}\right],\quad(49)$$

$$\operatorname{Tr}\left[\gamma^{-1}\right]_{\mathcal{K}_{T}}^{*}\left(\mathcal{L}_{T}-\gamma^{-1}\right)_{\mathcal{K}_{T}}^{*}\left(\gamma_{\mathcal{K}_{T}}^{*}\right)^{-1}\left(\gamma_{\mathcal{K}_{T}}\right),\tag{49}$$

$$= \operatorname{Tr}\left[\left(\mathcal{I}_T - \gamma^{-1} \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^* \right)^{-1} \gamma^{-1} \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^* \right],$$
(50)

where (48) is by (47), and (50) is by the cyclic property of trace. Noting that the condition $\gamma \mathcal{I}_T \succ \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}$ is equivalent to $\gamma \mathcal{I}_T \succ \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^*$, we expand $(\mathcal{I}_T - \gamma^{-1} \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^*)^{-1}$ in (50) by the following Neumann series:

$$\left(\mathcal{I}_T - \gamma^{-1} \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^*\right)^{-1} = \sum_{k=0}^{\infty} \left(\gamma^{-1} \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^*\right)^k.$$
(51)

Thus, the expression in (50) can be written equivalently as

$$\operatorname{Tr}\left[\left(\mathcal{I}_{T}-\gamma^{-1}\mathcal{T}_{\mathcal{K}_{T}}\mathcal{T}_{\mathcal{K}_{T}}^{*}\right)^{-1}\gamma^{-1}\mathcal{T}_{\mathcal{K}_{T}}\mathcal{T}_{\mathcal{K}_{T}}^{*}\right]=\operatorname{Tr}\left[\sum_{k=0}^{\infty}\left(\gamma^{-1}\mathcal{T}_{\mathcal{K}_{T}}\mathcal{T}_{\mathcal{K}_{T}}^{*}\right)^{k+1}\right],$$
(52)

$$= \operatorname{Tr}\left[\sum_{k=1}^{\infty} \left(\gamma^{-1} \mathcal{T}_{\mathcal{K}_{T}} \mathcal{T}_{\mathcal{K}_{T}}^{*}\right)^{k}\right], \qquad (53)$$

$$= \operatorname{Tr}\left[\left(\mathcal{I}_T - \gamma^{-1} \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^* \right)^{-1} - \mathcal{I}_T \right], \qquad (54)$$

giving the desired expression in (41). The desired expression in (43) can be obtained easily following similar algebraic manipulations. \Box

Proof of Lemma 3.3: Let \mathcal{K}_T be a given estimator, which can be non-causal. We have that

$$\mathcal{T}_{\mathcal{K}_T}\mathcal{T}^*_{\mathcal{K}_T} = \begin{bmatrix} \mathcal{K}_T \mathcal{H}_T - \mathcal{L}_T & \mathcal{K}_T \end{bmatrix} \begin{bmatrix} \mathcal{H}^*_T \mathcal{K}^*_T - \mathcal{L}^*_T \\ \mathcal{K}^*_T \end{bmatrix},$$
(55)

$$= (\mathcal{K}_T \mathcal{H}_T - \mathcal{L}_T)(\mathcal{K}_T \mathcal{H}_T - \mathcal{L}_T)^* + \mathcal{K}_T \mathcal{K}_T^*,$$
(56)

$$= \mathcal{K}_T (\mathcal{I}_T + \mathcal{H}_T \mathcal{H}_T^*) \mathcal{K}_T^* - \mathcal{K}_T \mathcal{H}_T \mathcal{L}_T^* - \mathcal{L}_T \mathcal{H}_T^* \mathcal{K}_T^* + \mathcal{L}_T \mathcal{L}_T^*,$$
⁽⁵⁷⁾

$$\stackrel{(a)}{=} (\mathcal{K}_T - \mathcal{K}_T^{\circ})(\mathcal{I}_T + \mathcal{H}_T \mathcal{H}_T^*)(\mathcal{K}_T - \mathcal{K}_T^{\circ})^* + \mathcal{L}_T \mathcal{L}_T^* - \mathcal{K}_T^{\circ}(\mathcal{I}_T + \mathcal{H}_T \mathcal{H}_T^*)(\mathcal{K}_T^{\circ})^*,$$
(58)

where $\mathcal{K}_T^{\circ} \coloneqq \mathcal{L}_T \mathcal{H}_T^* (\mathcal{I}_T + \mathcal{H}_T \mathcal{H}_T^*)^{-1}$ and (a) is obtained from completion of squares. Moreover, observe that

$$\mathcal{T}_{\mathcal{K}_T^\circ} \mathcal{T}_{\mathcal{K}_T^\circ}^* = \mathcal{L}_T \mathcal{L}_T^* - \mathcal{K}_T^\circ (\mathcal{I}_T + \mathcal{H}_T \mathcal{H}_T^*) (\mathcal{K}_T^\circ)^*,$$
(59)

$$= \mathcal{L}_T \mathcal{L}_T^* - \mathcal{L}_T \mathcal{H}_T^* (\mathcal{I}_T + \mathcal{H}_T \mathcal{H}_T^*)^{-1} \mathcal{H}_T \mathcal{L}_T^*,$$
(60)

$$= \mathcal{L}_T (\mathcal{I}_T - \mathcal{H}_T^* (\mathcal{I}_T + \mathcal{H}_T \mathcal{H}_T^*)^{-1} \mathcal{H}_T) \mathcal{L}_T^*,$$
(61)

$$\stackrel{(b)}{=} \mathcal{L}_T (\mathcal{I}_T + \mathcal{H}_T^* \mathcal{H}_T)^{-1} \mathcal{L}_T^*, \tag{62}$$

where (b) follows from matrix inversion identity.

Thus, we have that

$$\mathcal{T}_{\mathcal{K}_T}\mathcal{T}^*_{\mathcal{K}_T} = (\mathcal{K}_T - \mathcal{K}^{\circ}_T)(\mathcal{I}_T + \mathcal{H}_T\mathcal{H}^*_T)(\mathcal{K}_T - \mathcal{K}^{\circ}_T)^* + \mathcal{T}_{\mathcal{K}^{\circ}_T}\mathcal{T}^*_{\mathcal{K}^{\circ}_T} \neq \mathcal{T}^{*}_{\mathcal{K}^{\circ}_T}\mathcal{T}^*_{\mathcal{K}^{\circ}_T}$$
(63)

Now, consider Problem 2.3 without the causality constraint on the estimator. Using the strong duality result in Theorem C.5, we can express Eq. (8) equivalently as

$$\inf_{\gamma \ge 0} \inf_{\mathcal{K}_T} \gamma \rho_T^2 + \gamma \operatorname{Tr} \left[(\mathcal{I}_T - \gamma^{-1} \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^*)^{-1} - \mathcal{I}_T \right] \quad \text{s.t.} \quad \gamma \mathcal{I}_T \succ \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^*.$$
(64)

Fixing $\gamma \geq 0$, we focus on the subproblem

$$\inf_{\mathcal{K}_T} \gamma \operatorname{Tr} \left[(\mathcal{I}_T - \gamma^{-1} \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^*)^{-1} \right] \quad \text{s.t.} \quad \gamma \mathcal{I}_T \succ \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^*.$$
(65)

Using the identity in (63), we can rewrite (65) in terms \mathcal{K}_T° as follows

$$\inf_{\mathcal{K}_T} \gamma^2 \operatorname{Tr} \left[(\gamma \mathcal{I}_T - (\mathcal{K}_T - \mathcal{K}_T^{\circ})(\mathcal{I}_T + \mathcal{H}_T \mathcal{H}_T^{*})(\mathcal{K}_T - \mathcal{K}_T^{\circ})^* - \mathcal{T}_{\mathcal{K}_T^{\circ}} \mathcal{T}_{\mathcal{K}_T^{\circ}}^{*})^{-1} \right] \text{ s.t. } \gamma \mathcal{I}_T \succ \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T^{*}}^{*}.$$

Since the mapping $\mathcal{X} \mapsto (\mathcal{I}_T - \mathcal{X})^{-1}$ is operator monotone, the minimum over \mathcal{K}_T is attained by \mathcal{K}_T° and the optimal value is given by the following optimization:

$$\inf_{\gamma \ge 0} \gamma \rho_T^2 + \gamma \operatorname{Tr} \left[(\mathcal{I}_T - \gamma^{-1} \mathcal{T}_{\mathcal{K}_T^\circ} \mathcal{T}_{\mathcal{K}_T^\circ}^*)^{-1} - \mathcal{I}_T \right] \quad \text{s.t.} \quad \gamma \mathcal{I}_T \succ \mathcal{T}_{\mathcal{K}_T^\circ} \mathcal{T}_{\mathcal{K}_T^\circ}^*.$$
(66)

C.3 Proof of Theorem 3.4

Proof. Using the strong duality result in Theorem C.5, we can express Eq. (8) equivalently as

$$\inf_{\substack{\gamma \ge 0\\ \mathcal{K}_T \in \mathscr{K}}} \gamma(\rho_T^2 - \operatorname{Tr}(\mathcal{I}_T)) + \gamma^2 \operatorname{Tr}\left[(\gamma \mathcal{I}_T - \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^*)^{-1} \right] \quad \text{s.t.} \quad \gamma \mathcal{I}_T \succ \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^*.$$
(67)

Notice that we can express the rhs as

$$\gamma^{2} \operatorname{Tr} \left[\left(\gamma \mathcal{I}_{T} - \mathcal{T}_{\mathcal{K}_{T}} \mathcal{T}_{\mathcal{K}_{T}}^{*} \right)^{-1} \right] = \inf_{\mathcal{X}_{T} \succ 0} \operatorname{Tr}(\mathcal{X}_{T}) \text{ s.t. } \mathcal{X}_{T} \succcurlyeq \gamma^{2} (\gamma \mathcal{I}_{T} - \mathcal{T}_{\mathcal{K}_{T}} \mathcal{T}_{\mathcal{K}_{T}}^{*})^{-1}.$$
(68)

Using the Schur complement, we can rewrite the constraint $\mathcal{X}_T \succcurlyeq \gamma^2 (\gamma \mathcal{I}_T - \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^*)^{-1}$ as

$$\begin{bmatrix} \mathcal{X}_T & \gamma \mathcal{I}_T \\ \gamma \mathcal{I}_T & \gamma \mathcal{I}_T - \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^* \end{bmatrix} \succeq 0,$$
(69)

where we used the fact that $\gamma \mathcal{I}_T \succ \mathcal{T}_{\mathcal{K}_T} \mathcal{T}_{\mathcal{K}_T}^*$. Using the identity in (63), we can rewrite the matrix inequality (69) as

$$\begin{bmatrix} \mathcal{X}_T & \gamma \mathcal{I}_T \\ \gamma \mathcal{I}_T & \gamma \mathcal{I}_T - \mathcal{T}_{\mathcal{K}_T^\circ} \mathcal{T}_{\mathcal{K}_T^\circ}^* \end{bmatrix} - \begin{bmatrix} 0 \\ (\mathcal{K}_T - \mathcal{K}_T^\circ) \end{bmatrix} (\mathcal{I}_T + \mathcal{H}_T \mathcal{H}_T^*) \begin{bmatrix} 0 & (\mathcal{K}_T - \mathcal{K}_T^\circ)^* \end{bmatrix} \succeq 0.$$
(70)

As $(\mathcal{I}_T + \mathcal{H}_T \mathcal{H}_T^*) \succ 0$, by Schur complement theorem, we can reformulate the matrix inequality above as

$$\begin{bmatrix} \mathcal{X}_T & \gamma \mathcal{I}_T & 0\\ \gamma \mathcal{I}_T & \gamma \mathcal{I}_T - \mathcal{T}_{\mathcal{K}_T^\circ} \mathcal{T}_{\mathcal{K}_T^\circ}^* & \mathcal{K}_T - \mathcal{K}_T^\circ\\ 0 & (\mathcal{K}_T - \mathcal{K}_T^\circ)^* & (\mathcal{I}_T + \mathcal{H}_T \mathcal{H}_T^*)^{-1} \end{bmatrix} \succeq 0.$$
(71)

D Proofs of Theorems Related to Infinite-Horizon Filtering

D.1 Proof of Lemma 3.7

Theorem D.1 (Strong Duality in the Infinite-Horizon). Let \mathcal{K} be a linear and time-invariant estimator (which can be non-causal in general) with bounded H_{∞} norm. Under the Assumptions 2.5 and 3.2, the infinite-horizon worst-case MSE (10) suffered by \mathcal{K} , i.e.,

$$\overline{\mathsf{E}}(\mathcal{K},\rho) = \limsup_{T \to \infty} \frac{1}{T} \sup_{\mathbb{P}_T \in \mathscr{W}_T(\mathbb{P}^\circ_T,\rho_T)} \mathbb{E}_{\mathbb{P}_T} \left[\|\mathbf{e}_T(\boldsymbol{\xi}_T,\mathcal{K})\|^2 \right],$$
(72)

attains a finite value and is equivalent to the following dual problem:

$$\overline{\mathsf{E}}(\mathcal{K},\rho) = \inf_{\gamma \ge 0} \gamma \rho^2 + \gamma \operatorname{Tr}\left[(\mathcal{I} - \gamma^{-1} \mathcal{T}_{\mathcal{K}} \mathcal{T}_{\mathcal{K}}^*)^{-1} - \mathcal{I} \right] \quad s.t. \quad \gamma \mathcal{I} \succ \mathcal{T}_{\mathcal{K}} \mathcal{T}_{\mathcal{K}}^*.$$
(73)

Furthermore, the worst-case disturbance, ξ_{\star} , can be identified from the nominal disturbance, ξ_{\circ} , as

$$\boldsymbol{\xi}_{\star} = (\mathcal{I} - \gamma_{\star}^{-1} \mathcal{T}_{\mathcal{K}}^{*} \mathcal{T}_{\mathcal{K}})^{-1} \boldsymbol{\xi}_{\circ}, \tag{74}$$

where γ_{\star} is the optimal solution of (73) and solves the following equation uniquely:

$$\operatorname{Tr}\left[\left(\left(\mathcal{I}-\gamma_{\star}^{-1}\mathcal{T}_{\mathcal{K}}\mathcal{T}_{\mathcal{K}}^{*}\right)^{-1}-\mathcal{I}\right)^{2}\right]=\rho^{2}.$$
(75)

Proof. The proof of this result closely tracks the proof of Thm. 5 in [73]. By replacing $C_{\mathcal{K}}$ in the proof of Thm. 5 in [73] with $\mathcal{T}_{\mathcal{K}}\mathcal{T}_{\mathcal{K}}^*$.

Proof of Lemma 3.7 : The proof follows closely from the proof of Lemma 3.3 in Appendix C.2. Let \mathcal{K} be linear time-invariant estimator, which can be non-causal, with bounded H_{∞} norm. We have that

$$\mathcal{T}_{\mathcal{K}}\mathcal{T}_{\mathcal{K}}^{*} = (\mathcal{K} - \mathcal{K}_{\circ})(\mathcal{I} + \mathcal{H}\mathcal{H}^{*})(\mathcal{K} - \mathcal{K}_{\circ})^{*} + \mathcal{T}_{\mathcal{K}_{\circ}}\mathcal{T}_{\mathcal{K}_{\circ}}^{*} \succcurlyeq \mathcal{T}_{\mathcal{K}_{\circ}}\mathcal{T}_{\mathcal{K}_{\circ}}^{*}$$
(76)
where $\mathcal{K}^{\circ} \coloneqq \mathcal{L}\mathcal{H}^{*}(\mathcal{I} + \mathcal{H}\mathcal{H}^{*})^{-1}$ and $\mathcal{T}_{\mathcal{K}_{T}^{\circ}}\mathcal{T}_{\mathcal{K}_{T}^{\circ}}^{*} = \mathcal{L}(\mathcal{I} + \mathcal{H}^{*}\mathcal{H})^{-1}\mathcal{L}^{*}.$

Now, consider Problem 2.6 without the causality constraint on the estimator. Using the strong duality result in Theorem D.1, we can express Eq. (11) equivalently as

$$\inf_{\gamma \ge 0} \inf_{\mathcal{K}} \gamma \rho^2 + \gamma \operatorname{Tr} \left[\left(\mathcal{I} - \gamma^{-1} \mathcal{T}_{\mathcal{K}} \mathcal{T}_{\mathcal{K}}^* \right)^{-1} - \mathcal{I} \right] \quad \text{s.t.} \quad \gamma \mathcal{I} \succ \mathcal{T}_{\mathcal{K}} \mathcal{T}_{\mathcal{K}}^*.$$
(77)

Fixing $\gamma \geq 0$, we focus on the subproblem

$$\inf_{\mathcal{K}} \gamma \operatorname{Tr} \left[\left(\mathcal{I} - \gamma^{-1} \mathcal{T}_{\mathcal{K}} \mathcal{T}_{\mathcal{K}}^* \right)^{-1} \right] \quad \text{s.t.} \quad \gamma \mathcal{I} \succ \mathcal{T}_{\mathcal{K}} \mathcal{T}_{\mathcal{K}}^*.$$
(78)

Using the identity in (76), we can rewrite (78) in terms \mathcal{K}_{\circ} as follows

$$\inf_{\mathcal{K}} \gamma^2 \operatorname{Tr} \left[(\gamma \mathcal{I} - (\mathcal{K} - \mathcal{K}_{\circ})(\mathcal{I} + \mathcal{H}\mathcal{H}^*)(\mathcal{K} - \mathcal{K}_{\circ})^* - \mathcal{T}_{\mathcal{K}_{\circ}}\mathcal{T}_{\mathcal{K}_{\circ}}^*)^{-1} \right] \text{ s.t. } \gamma \mathcal{I} \succ \mathcal{T}_{\mathcal{K}}\mathcal{T}_{\mathcal{K}}^*.$$

Since the mapping $\mathcal{X} \mapsto (\mathcal{I} - \mathcal{X})^{-1}$ is operator monotone, the minimum over \mathcal{K} is attained by \mathcal{K}_{\circ} and the optimal value is given by the following optimization:

$$\inf_{\gamma \ge 0} \gamma \rho^2 + \gamma \operatorname{Tr} \left[\left(\mathcal{I} - \gamma^{-1} \mathcal{T}_{\mathcal{K}_{\circ}} \mathcal{T}_{\mathcal{K}_{\circ}}^* \right)^{-1} - \mathcal{I} \right] \quad \text{s.t.} \quad \gamma \mathcal{I} \succ \mathcal{T}_{\mathcal{K}_{\circ}} \mathcal{T}_{\mathcal{K}_{\circ}}^*.$$
(79)

D.2 Proofs of Theorem 3.8 and Corollary 3.9

Lemma D.2 (Wiener-Hopf Method [85]). For a bounded and positive definite Toeplitz operator $\mathcal{M} \succ 0$, let $\mathcal{M} \mapsto \Phi(\mathcal{M})$ be a mapping defined as

$$\Phi(\mathcal{M}) \triangleq \inf_{\mathcal{K} \in \mathscr{K}} \operatorname{Tr} \left(\mathcal{T}_{\mathcal{K}} \mathcal{T}_{\mathcal{K}}^* \mathcal{M} \right).$$
(80)

Denote by $\mathcal{M} = \mathcal{U}^*\mathcal{U}$ and $\Delta\Delta^* = \mathcal{I} + \mathcal{H}\mathcal{H}^*$ the canonical spectral factorizations² where \mathcal{U}, Δ as well as their inverses $\mathcal{U}^{-1}, \Delta^{-1}$ are causal operators. The following statements hold:

i. The optimal causal solution to (19) is given by

$$\mathcal{K} = \mathcal{U}^{-1} \left\{ \mathcal{U} \mathcal{K}_{\circ} \Delta \right\}_{+} \Delta^{-1} = \mathcal{K}_{H_{2}} + \mathcal{U}^{-1} \left\{ \mathcal{U} \left\{ \mathcal{K}_{\circ} \Delta \right\}_{-} \right\}_{+} \Delta^{-1},$$
(81)

where $\mathcal{K}_{H_2} \coloneqq {\mathcal{K}_{\circ}\Delta}_+ \Delta^{-1}$ is the Kalman filter.

ii. The function Φ can be written in closed form as

$$\Phi(\mathcal{M}) = \operatorname{Tr}\left[\left\{\mathcal{U}\mathcal{K}_{\circ}\Delta\right\}_{-}\left\{\mathcal{U}\mathcal{K}_{\circ}\Delta\right\}_{-}^{*}\right] + \operatorname{Tr}\left(\mathcal{T}_{\mathcal{K}_{\circ}}\mathcal{T}_{\mathcal{K}_{\circ}}^{*}\mathcal{M}\right),\tag{82}$$

where $\mathcal{T}_{\mathcal{K}_{\circ}}\mathcal{T}^*_{\mathcal{K}_{\circ}} = \mathcal{L}(\mathcal{I} + \mathcal{H}^*\mathcal{H})^{-1}\mathcal{L}^*.$

²The canonical spectral factorization is essentially the Toeplitz operator counterpart of Cholesky decomposition of finite-dimensional matrices.

iii. The gradient of Φ has the following closed form

$$\nabla \Phi(\mathcal{M}) = \mathcal{T}_{\mathcal{K}} \mathcal{T}_{\mathcal{K}}^* = \mathcal{U}^{-1} \left\{ \mathcal{U} \mathcal{K}_{\circ} \Delta \right\}_{-}^* \left\{ \mathcal{U} \mathcal{K}_{\circ} \Delta \right\}_{-}^* \mathcal{U}^{-*} + \mathcal{T}_{\mathcal{K}_{\circ}} \mathcal{T}_{\mathcal{K}_{\circ}}^*.$$
(83)

Proof. Using the identity (76) and the cyclic property of Tr, the objective can be written as,

$$\inf_{\mathcal{K}\in\mathscr{K}} \operatorname{Tr}\left[(\mathcal{K}-\mathcal{K}_{\circ})\Delta\Delta^{*}(\mathcal{K}-\mathcal{K}_{\circ})^{*}\mathcal{M}\right] = \inf_{\mathcal{K}\in\mathscr{K}} \operatorname{Tr}\left[(\mathcal{K}\Delta-\mathcal{K}_{\circ}\Delta)(\mathcal{K}\Delta-\mathcal{K}_{\circ}\Delta)^{*}\mathcal{U}^{*}\mathcal{U}\right]$$
(84)

$$= \inf_{\mathcal{K} \in \mathscr{K}} \inf_{\mathcal{K} \in \mathscr{K}} \operatorname{Tr} \left[(\mathcal{U}\mathcal{K}\Delta - \mathcal{U}\mathcal{K}_{\circ}\Delta) (\mathcal{U}\mathcal{K}\Delta - \mathcal{U}\mathcal{K}_{\circ}\Delta)^{*} \right]$$

(85)

$$= \inf_{\mathcal{K}\in\mathscr{K}} \left\| \mathcal{U}\mathcal{K}\Delta - \mathcal{U}\mathcal{K}_{\circ}\Delta \right\|_{H_{2}}^{2},$$
(86)

where $\|\cdot\|_2$ represents the H_2 norm. Since Δ, \mathcal{K} and \mathcal{U} are causal, and $\mathcal{U}\mathcal{K}_{\circ}\Delta$ can be broken into causal and non-causal parts, it is evident that the (causal) filter that minimises the objective is the one that makes the term $\mathcal{U}\mathcal{K}\Delta - \mathcal{U}\mathcal{K}_{\circ}\Delta$ strictly anti-causal, cancelling off the causal part of $\Delta\mathcal{K}_{\circ}\mathcal{L}$. This means that the optimal filter satisfies,

$$\mathcal{UK}\Delta = \left\{ \mathcal{UK}_{\circ}\Delta \right\}_{+}.$$
(87)

Also, since \mathcal{U}^{-1} and Δ^{-1} are causal, the optimal causal filter is given by

$$\mathcal{K} = \mathcal{U}^{-1} \left\{ \mathcal{U} \mathcal{K}_{\circ} \Delta \right\}_{+} \Delta^{-1}.$$
(88)

Furthermore, using the identity $\mathcal{K}_{\circ}\Delta = \{\mathcal{K}_{\circ}\Delta\}_{+} + \{\mathcal{K}_{\circ}\Delta\}_{-}$, we get

$$\mathcal{K} = \mathcal{U}^{-1} \left\{ \mathcal{U} \{ \mathcal{K}_{\circ} \Delta \}_{+} \right\}_{+} \Delta^{-1} + \mathcal{U}^{-1} \left\{ \mathcal{U} \{ \mathcal{K}_{\circ} \Delta \}_{-} \right\}_{+} \Delta^{-1}, \tag{89}$$

$$= \mathcal{U}^{-1}\mathcal{U}\{\mathcal{K}_{\circ}\Delta\}_{+}\Delta^{-1} + \mathcal{U}^{-1}\{\mathcal{U}\{\mathcal{K}_{\circ}\Delta\}_{-}\}_{+}\Delta^{-1},\tag{90}$$

$$= \left\{ \mathcal{K}_{\circ} \Delta \right\}_{+} \Delta^{-1} + \mathcal{U}^{-1} \left\{ \mathcal{U} \left\{ \mathcal{K}_{\circ} \Delta \right\}_{-} \right\}_{+} \Delta^{-1}.$$
(91)

Plugging this solution to $\mathcal{T}_{\mathcal{K}}\mathcal{T}_{\mathcal{K}}^*$, we get

$$\mathcal{T}_{\mathcal{K}}\mathcal{T}_{\mathcal{K}}^* = \mathcal{U}^{-1}(\mathcal{U}\mathcal{K}\Delta - \mathcal{U}\mathcal{K}_{\circ}\Delta)(\mathcal{U}\mathcal{K}\Delta - \mathcal{U}\mathcal{K}_{\circ}\Delta)^*\mathcal{U}^{-*} + \mathcal{T}_{\mathcal{K}_{\circ}}\mathcal{T}_{\mathcal{K}_{\circ}}^*, \tag{92}$$

$$= \mathcal{U}^{-1}(\{\mathcal{U}\mathcal{K}_{\circ}\Delta\}_{+} - \mathcal{U}\mathcal{K}_{\circ}\Delta)(\{\mathcal{U}\mathcal{K}_{\circ}\Delta\}_{+} - \mathcal{U}\mathcal{K}_{\circ}\Delta)^{*}\mathcal{U}^{-*} + \mathcal{T}_{\mathcal{K}_{\circ}}\mathcal{T}_{\mathcal{K}_{\circ}}^{*},$$
(93)

$$= \mathcal{U}^{-1} \left\{ \mathcal{U}\mathcal{K}_{\circ}\Delta \right\}_{-} \left\{ \mathcal{U}\mathcal{K}_{\circ}\Delta \right\}_{-}^{*} \mathcal{U}^{-*} + \mathcal{T}_{\mathcal{K}_{\circ}}\mathcal{T}_{\mathcal{K}_{\circ}}^{*}.$$

$$\tag{94}$$

Then, the objective becomes

$$\operatorname{Tr}(\mathcal{T}_{\mathcal{K}}\mathcal{T}_{\mathcal{K}}^{*}\mathcal{M}) = \operatorname{Tr}(\mathcal{U}^{-1}\left\{\mathcal{U}\mathcal{K}_{\circ}\Delta\right\}_{-}^{*}\left\{\mathcal{U}\mathcal{K}_{\circ}\Delta\right\}_{-}^{*}\mathcal{U}^{*}\mathcal{M}) + \operatorname{Tr}(\mathcal{T}_{\mathcal{K}_{\circ}}\mathcal{T}_{\mathcal{K}_{\circ}}^{*}\mathcal{M}),$$
(95)

$$= \operatorname{Tr}(\{\mathcal{U}\mathcal{K}_{\circ}\Delta\}_{-} \{\mathcal{U}\mathcal{K}_{\circ}\Delta\}_{-}^{*}) + \operatorname{Tr}(\mathcal{T}_{\mathcal{K}_{\circ}}\mathcal{T}_{\mathcal{K}_{\circ}}^{*}\mathcal{M}).$$
(96)

Finally, by Danskin theorem [90], the gradient of Φ is simply $\mathcal{T}_{\mathcal{K}}\mathcal{T}_{\mathcal{K}}^*$ evaluated at the optimal \mathcal{K} as given in (94).

Lemma D.3. Let $\gamma > \inf_{\mathcal{K} \in \mathscr{K}} \|\mathcal{T}_{\mathcal{K}}\|_{\infty}^2$ be fixed. Then, we have the following duality

$$\inf_{\substack{\mathcal{K}\in\mathscr{K},\\\gamma\mathcal{I}\succ\mathcal{T}_{\mathcal{K}}\mathcal{T}_{\mathcal{K}}^{*}}} \gamma \operatorname{Tr}\left[\left(\mathcal{I}-\gamma^{-1}\mathcal{T}_{\mathcal{K}}\mathcal{T}_{\mathcal{K}}^{*}\right)^{-1} - \mathcal{I} \right] = \sup_{\mathcal{M}\succ 0} \inf_{\mathcal{K}\in\mathscr{K}} \operatorname{Tr}(\mathcal{T}_{\mathcal{K}}\mathcal{T}_{\mathcal{K}}^{*}\mathcal{M}) - \gamma \operatorname{Tr}\left(\mathcal{M}-2\sqrt{\mathcal{M}}+\mathcal{I}\right).$$
(97)

Proof. The convex mapping $\mathcal{X} \mapsto \operatorname{Tr} \mathcal{X}^{-1}$ for $\mathcal{X} \succ 0$ can be expressed via Fenchel duality as

$$\sup_{\mathcal{M}\succ 0} -\operatorname{Tr}(\mathcal{X}\mathcal{M}) + 2\operatorname{Tr}(\sqrt{\mathcal{M}}) = \begin{cases} \operatorname{Tr}(\mathcal{X}^{-1}), & \text{if } \mathcal{X}\succ 0\\ +\infty, & \text{o.w.} \end{cases}$$
(98)

Using the identity (98), we rewrite the original problem as,

$$\inf_{\mathcal{K}\in\mathscr{K}} \sup_{\mathcal{M}\succ 0} \operatorname{Tr}(\mathcal{T}_{\mathcal{K}}\mathcal{T}_{\mathcal{K}}^{*}\mathcal{M}) - \gamma \operatorname{Tr}\left(\mathcal{M} - 2\sqrt{\mathcal{M}} + \mathcal{I}\right).$$
(99)

Notice that, the objective above is strictly convex in \mathcal{K} and strictly concave in \mathcal{M} . Furthermore, the primal and dual problems are feasible since $\gamma > \inf_{\mathcal{K} \in \mathscr{K}} \|\mathcal{T}_{\mathcal{K}}\|_{\infty}^2$. Thus, the proof follows from the minimax theorem.

Proof of Theorem 3.8: Consider Problem 2.6. Using the strong duality result in Theorem D.1, we can express Eq. (11) equivalently as

$$\inf_{\gamma \ge 0} \inf_{\mathcal{K} \in \mathscr{K}} \gamma \rho^2 + \gamma \operatorname{Tr} \left[(\mathcal{I} - \gamma^{-1} \mathcal{T}_{\mathcal{K}} \mathcal{T}_{\mathcal{K}}^*)^{-1} - \mathcal{I} \right] \quad \text{s.t.} \quad \gamma \mathcal{I} \succ \mathcal{T}_{\mathcal{K}} \mathcal{T}_{\mathcal{K}}^*.$$
(100)

Fixing $\gamma \geq 0$, we focus on the subproblem

$$\inf_{\mathcal{K}} \gamma \operatorname{Tr} \left[\left(\mathcal{I} - \gamma^{-1} \mathcal{T}_{\mathcal{K}} \mathcal{T}_{\mathcal{K}}^* \right)^{-1} - \mathcal{I} \right] \quad \text{s.t.} \quad \gamma \mathcal{I} \succ \mathcal{T}_{\mathcal{K}} \mathcal{T}_{\mathcal{K}}^*.$$
(101)

Using Lemma D.3, we can reformulate (101) as

$$\sup_{\mathcal{M}\succ 0} \inf_{\mathcal{K}\in\mathscr{K}} \operatorname{Tr}(\mathcal{T}_{\mathcal{K}}\mathcal{T}_{\mathcal{K}}^{*}\mathcal{M}) - \gamma \operatorname{Tr}\left(\mathcal{M}-2\sqrt{\mathcal{M}}+\mathcal{I}\right).$$
(102)

Thus, the original formulation in (100) can be expressed as

$$\inf_{\gamma \ge 0} \sup_{\mathcal{M} \succ 0} \inf_{\mathcal{K} \in \mathscr{K}} \operatorname{Tr}(\mathcal{T}_{\mathcal{K}} \mathcal{T}_{\mathcal{K}}^* \mathcal{M}) + \gamma \left(\rho^2 - \operatorname{Tr}(\mathcal{M} - 2\sqrt{\mathcal{M}} + \mathcal{I})\right).$$
(103)

Note that the objective above is affine in $\gamma \ge 0$ and strictly concave in \mathcal{M} . Moreover, primal and dual feasibility hold, enabling the exchange of $\inf_{\gamma>0} \sup_{\mathcal{M}\succ 0}$ resulting in

$$\sup_{\mathcal{M}\succ 0} \inf_{\mathcal{K}\in\mathscr{K}} \inf_{\gamma\geq 0} \operatorname{Tr}(\mathcal{T}_{\mathcal{K}}\mathcal{T}_{\mathcal{K}}^*\mathcal{M}) + \gamma\left(\rho^2 - \operatorname{Tr}(\mathcal{M} - 2\sqrt{\mathcal{M}} + \mathcal{I})\right),$$
(104)

where the inner minimization over γ reduces the problem to its constrained version in Eq. (14).

Finally, the form of the optimal \mathcal{K}_{\star} follows from the Wiener-Hopf technique in Lemma D.2 and the optimal γ_{\star} and \mathcal{M}_{\star} can be obtained using the strong duality theorem in (D.1).

Proof of Corollary 3.9: This result follows immediately from the finiteness of the time-averaged infinite-horizon MSE.

E Additional Discussion on Frequency-domain Optimization Method

E.1 Pseudocode for Frequency-domain Iterative Optimization Method Solving Eq. (14)

Algorithm 1 Frequency-domain iterative optimization method solving Eq. (14)

1: Input: Radius $\rho > 0$, state-space model (A, B, C_y, C_s) , discretization N > 0, tolerance $\epsilon > 0$

- 2: Compute $(\overline{A}, \overline{B}, \overline{C})$ from (A, B, C_y, C_s) using (113)
- 3: Generate frequency samples $\mathbb{T}_N := \{ e^{j2\pi n/N} \mid n = 0, \dots, N-1 \}$
- 4: Initialize $M_0(z) \leftarrow I$ for $z \in \mathbb{T}_N$, and $k \leftarrow 0$
- 5: repeat
- 6: Set the step size $\eta_k \leftarrow \frac{2}{k+2}$
- 7: Compute the spectral factor $U_k(z) \leftarrow \text{SpectralFactor}(M_k)$ (see Appendix E.5)

8: Compute the parameter
$$\Gamma_k \leftarrow \frac{1}{N} \sum_{z \in \mathbb{T}_N} U_k(z) \overline{C} (I - z\overline{A})^{-1}$$
 (see Appendix E.4)

9: Compute the gradient for $z \in \mathbb{T}_N$ (see Appendix E.4)

$$G_k(z) \leftarrow U_k(z)^{-1} \Gamma_k(I - z\overline{A})^{-1} \overline{B} \overline{B}^* (I - z\overline{A})^{-*} \Gamma_k^* U_k(z)^{-*} + T_{K_o}(z) T_{K_o}(z)^*$$

10: Solve the linear subproblem (20a) via bisection (see Appendix E.6)

$$M_k(z) \leftarrow \texttt{Bisection}(G_k, \rho, \epsilon) \text{ for } z \in \mathbb{T}_N.$$

- 11: Set $M_{k+1}(z) \leftarrow (1 \eta_k)M_k(z) + \eta_k \widetilde{M}_k(z)$ for $z \in \mathbb{T}_N$.
- 12: Increment $k \leftarrow k+1$
- 13: **until** $||M_{k+1} M_k|| / ||M_k|| \le \epsilon$
- 14: Compute $K(z) \leftarrow \text{RationalApproximate}(M_{k+1})$ (see Appendix E.8)

E.2 Frequency-Domain Characterization of the Optimal Solution of Eq. (11)

We present the frequency-domain formulation of the saddle point $(\mathcal{K}_{\star}, \mathcal{M}_{\star})$ derived in Theorem 3.8 to reveal the structure of the solution. We first introduce the following useful results:

Lemma E.1 ([33, pg. 261]). Given $H(z) := C_y(zI - A)^{-1}B$, consider the canonical spectral factorization $\Delta(z)\Delta(z)^*I + H(z)H(z)^*$ for $z \in \mathbb{T}$. We have that

$$\Delta(z) = (I + C_y (zI - A)^{-1} F_P) R_e^{1/2}, \tag{105}$$

$$\Delta(z)^{-1} = R_e^{-1/2} (I - C_y (zI - A_P)^{-1} F_P), \tag{106}$$

where $R_e := I + C_y P C_y^*$, $F_P := (AP C_y^*) R_e^{-1}$, $A_P := A - F_P C_y$, and P is the unique positive semidefinite solution to the following discrete algebraic Riccati equation (DARE)

$$P = APA^* + BB^* - F_P R_e F_P^*.$$
 (107)

Denoting by $M_{\star}(z)$ and $T_{K_{\star}}(z)$ the transfer functions corresponding to the optimal \mathcal{M}_{\star} and $\mathcal{T}_{\mathcal{K}_{\star}}$, respectively, the optimality condition in (15) takes the equivalent form:

i.
$$M_{\star}(z) = \left(I - \gamma_{\star}^{-1} T_{K_{\star}}(z) T_{K_{\star}}(z)^{*}\right)^{-2},$$
 (108a)

$$ii. T_{K_{\star}}(z)T_{K_{\star}}(z)^{*} = U_{\star}(z)^{-1} \{\mathcal{U}_{\star}\mathcal{S}\}_{-}(z) \{\mathcal{U}_{\star}\mathcal{S}\}_{-}(z)^{*}U_{\star}(z)^{-*} + T_{K_{\circ}}(z)T_{K_{\circ}}(z)^{*}, \qquad (108b)$$

iii. Tr
$$\left[\left((I - \gamma_{\star}^{-1} T_{K_{\star}}(z) T_{K_{\star}}(z)^{*})^{-1} - I \right)^{2} \right] = \rho^{2},$$
 (108c)

where $S \coloneqq \{\mathcal{K}_{\circ}\Delta\}_{-}$ is a strictly anticausal operator and $U_{\star}(z)$ is the transfer function corresponding to the causal canonical factor \mathcal{U}_{\star}

The transfer function corresponding to the operator S takes a rational form as

$$S(z) \coloneqq \overline{C}(z^{-1}I - \overline{A})^{-1}\overline{B},\tag{109}$$

where $(\overline{A}, \overline{B}, \overline{C})$ are determined by the original state-space parameters (A, B, C_y, C_s) . The following lemma explicitly states this result.

Lemma E.2 ([33, pg. 261] and [38, Lem. 6]). We have that

$$\mathcal{K}_{\circ}\Delta = \mathcal{K}_{H_2}\Delta + \mathcal{S},\tag{110}$$

where \mathcal{K}_{H_2} is the nominal causal H_2 (aka Kalman) filter and $\mathcal{S} := {\mathcal{K}_{\circ}\Delta}_{-}$ is strictly anti-causal. Furthermore, the corresponding transfer functions take an explicit form as highlighted below

$$K_{H_2}(z) \coloneqq C_s P C_y^* R_e^{-1} + C_s (I - P C_y^* R_e^{-1} C_y) (zI - A_P)^{-1} F_P,$$
(111)

$$S(z) \coloneqq C_s P A_P^* (z^{-1} I - A_P^*)^{-1} C_y^* R_e^{-1/2},$$
(112)

where P, R_e , F_P , and A_P are defined as in Lemma E.1.

Thus, we have that

$$\overline{A} \triangleq A_P^*, \quad \overline{B} \triangleq C_y^* R_e^{-1/2}, \quad \overline{C} \triangleq C_s P A_P^*.$$
 (113)

Notice that for a causal U(z) and strictly anti-causal S(z), the strictly anti-causal part $\{U(z)S(z)\}_{-}$ may not have any poles from U(z), and all of its poles must be from the strictly anti-causal S(z). This observation is formally expressed in the following lemma.

Lemma E.3. Let \mathcal{U} be a causal and causally invertible operator, which can be non-rational in general. Then, the strictly anti-causal operator $\{\mathcal{US}\}_{-}$ admits a rational transfer function, i.e.,

$$\{\mathcal{US}\}_{-}(z) = \Gamma(z^{-1}I - \overline{A})^{-1}\overline{B}, \qquad (114)$$

where

$$\Gamma \triangleq \frac{1}{2\pi} \int_{-\pi}^{\pi} U(e^{j\omega}) \overline{C} (I - e^{j\omega} \overline{A})^{-1} d\omega.$$
(115)

Proof. Consider the z-transform expansions of U(z) and S(z):

$$U(z) = \sum_{k=0}^{\infty} \widehat{U}_k z^{-k}, \quad \text{and} \quad S(z) = \sum_{l=0}^{\infty} \overline{C} \,\overline{A}^l \,\overline{B} z^{l+1}, \tag{116}$$

where the time-domain coefficients \widehat{U}_k can be derived from the Fourier series integrals as

$$\widehat{U}_k \coloneqq \frac{1}{2\pi} \int_{-\pi}^{\pi} U(\mathrm{e}^{j\omega}) \mathrm{e}^{j\omega k} d\omega.$$
(117)

Multiplying U(z) and S(z) and taking the strictly anti-causal parts, *i.e.*, terms with positive powers of z, we get

$$\{U(z)S(z)\}_{-} = \left\{ \left(\sum_{k=0}^{\infty} \widehat{U}_k z^{-k}\right) \left(\sum_{l=0}^{\infty} \overline{C} \,\overline{A}^l \,\overline{B} z^{l+1}\right) \right\}_{-},\tag{118}$$

$$= \left(\sum_{k=0}^{\infty} \widehat{U}_k \overline{C} \overline{A}^k\right) \left(\sum_{l=0}^{\infty} \overline{A}^l \overline{B} z^{l+1}\right), \tag{119}$$

$$=\Gamma(z^{-1}I-\overline{A})^{-1}\overline{B},$$
(120)

where $\Gamma = \sum_{k=0}^{\infty} \widehat{U}_k \overline{C} \overline{A}^k$ which can be expressed as an integral

$$\Gamma = \frac{1}{2\pi} \int_{-\pi}^{\pi} U(e^{j\omega}) \overline{C} (I - e^{j\omega} \overline{A})^{-1} d\omega.$$
(121)

using Parseval's theorem.

E.3 Proofs of Lemma 4.1 and Corollary 4.2

Proof of Lemma 4.1: Using Lemma E.3, the frequency-domain optimality equations (108) can be reformulated explicitly as follows

i.
$$M_{\star}(z) = \left(I - \gamma_{\star}^{-1} T_{K_{\star}}(z) T_{K_{\star}}(z)^{*}\right)^{-2},$$
 (122a)

$$ii. T_{K_{\star}}(z)T_{K_{\star}}(z)^{*} = U_{\star}(z)^{-1}\Gamma_{\star}(I - z\overline{A})^{-1}\overline{B}\,\overline{B}^{*}(I - z\overline{A})^{-*}\Gamma_{\star}^{*}U_{\star}(z)^{-*} + T_{K_{\circ}}(z)T_{K_{\circ}}(z)^{*}, \quad (122b)$$

iii. Tr
$$\left[\left((I - \gamma_{\star}^{-1} T_{K_{\star}}(z) T_{K_{\star}}(z)^{*})^{-1} - I \right)^{2} \right] = \rho^{2},$$
 (122c)

where

$$\Gamma_{\star} \triangleq \frac{1}{2\pi} \int_{-\pi}^{\pi} U_{\star}(\mathrm{e}^{j\omega}) \overline{C} (I - \mathrm{e}^{j\omega} \overline{A})^{-1} d\omega, \qquad (123)$$

and $(\overline{A}, \overline{B}, \overline{C})$ are as in (113). This gives us the desired result.

Proof of Corollary 4.2: Define
$$S_{\star}(z) \coloneqq \Gamma_{\star}(I-z\overline{A})^{-1}\overline{B}$$
 for notational convenience. We rewrite the optimality conditions in (122) as

$$i. \ (U_{\star}(z)^{*}U_{\star}(z))^{-1/2} = I - \gamma_{\star}^{-1}T_{K_{\star}}(z)T_{K_{\star}}(z)^{*}$$
(124)

$$ii. T_{K_{\star}}(z)T_{K_{\star}}(z)^{*} = U_{\star}(z)^{-1}S_{\star}(z)S_{\star}(z)^{*}U_{\star}(z)^{-*} + T_{K_{\circ}}(z)T_{K_{\circ}}(z)^{*}$$
(125)

By plugging *ii*. into *i*., we get

$$0 = I - (U_{\star}(z)^{*}U_{\star}(z))^{-1/2} - \gamma_{\star}^{-1} \left(U_{\star}(z)^{-1}S_{\star}(z)S_{\star}(z)^{*}U_{\star}(z)^{-*} + T_{K_{\circ}}(z)T_{K_{\circ}}(z)^{*} \right) = 0, \quad (126)$$

Multiplying by $U_{\star}(z)$ from the left and by $U_{\star}(z)^*$ from the right, we get

$$0 = U_{\star}(z)U_{\star}(z)^{*} - (U_{\star}(z)U_{\star}(z)^{*})^{1/2} - \gamma_{\star}^{-1} \left(S_{\star}(z)S_{\star}(z)^{*} + U_{\star}(z)T_{K_{\circ}}(z)T_{K_{\circ}}(z)^{*}\right)U_{\star}(z)^{*},$$

which can be written further as

$$U_{\star}(z)U_{\star}(z)^{*} = \frac{1}{4} \left(I + \sqrt{I + 4\gamma^{-1} \left(S_{\star}(z)S_{\star}(z)^{*} + U_{\star}(z)T_{K_{\circ}}(z)^{*} \right) U_{\star}(z)^{*}} \right)^{2}.$$
 (127)

Notice that while $S_{\star}(z)S_{\star}(z)^*$ is rational, the expression above involves its positive definite square root, which does not generally preserve rationality, implying the desired result.

E.4 Additional Discussion on the Computation of Gradients

By the Wiener-Hopf technique discussed in Lemma D.2, the gradient $\mathcal{G}_k = \nabla \Phi(\mathcal{M}_k)$ can be obtained as

$$G_k(z) = U_k(z)^{-1} \{ \mathcal{U}_k \mathcal{K}_o \Delta \}_- (z) \{ \mathcal{U}_k \mathcal{K}_o \Delta \}_- (z)^* U_k^{-*} + T_{K_o} T_{K_o}^*,$$
(128)

where $U_k^* U_k = M_k$ is the unique spectral factorization. Furthermore, by Lemma E.3, we can reformulate the gradient $G_k(z)$ more explicitly as

$$G_k(z) = U_k(z)^{-1} \Gamma_k (I - z\overline{A})^{-1} \overline{B} \, \overline{B}^* (I - z\overline{A})^{-*} \Gamma_k^* U_k^{-*} + T_{K_o} T_{K_o}^*,$$
(129)

where

$$\Gamma_k \triangleq \frac{1}{2\pi} \int_{-\pi}^{\pi} U_k(\mathrm{e}^{j\omega}) \overline{C} (I - \mathrm{e}^{j\omega} \overline{A})^{-1} d\omega.$$
(130)

Here, the spectral factor $U_k(z)$ is obtained for $z \in \mathbb{T}_N$ by Appendix E.5. Similarly, the parameter Γ_k can be computed numerically using the trapezoid rule over the discrete domain \mathbb{T}_N , *i.e.*,

$$\Gamma_k \leftarrow \frac{1}{N} \sum_{z \in \mathbb{T}_N} U_k(z) \overline{C} (I - z\overline{A})^{-1}.$$
(131)

Noting that $T_{K_o}T_{K_o}^*$ is rational and depends only on the system, the gradient $G_k(z)$ can be efficiently computed for $z \in \mathbb{T}_N$.

E.5 Implementation of Spectral Factorization

To perform the spectral factorization of an irrational function M(z), we use a spectral factorization method via discrete Fourier transform, which returns samples of the spectral factor on the unit circle. First, we compute $\Lambda(z)$ for $z \in \mathbb{T}_N$, which is defined to be the logarithm of M(z), then we take the inverse discrete Fourier transform λ_k for k = 0, ..., N - 1 of $\Lambda(z)$ which we use to compute the spectral factorization as

$$U(z_n) \leftarrow \exp\left(\frac{1}{2}\lambda_0 + \sum_{k=1}^{N/2-1} \lambda_k z_n^{-k} + \frac{1}{2}(-1)^n \lambda_{N/2}\right)$$

for k = 0, ..., N - 1 where $z_n = e^{j2\pi n/N}$.

The method is efficient without requiring rational spectra, and the associated error term, featuring a purely imaginary logarithm, rapidly diminishes with an increased number of samples. It is worth noting that this method is explicitly designed for scalar functions.

Algorithm 2 SpectralFactor: Spectral Factorization via DFT

- 1: Input: Scalar positive spectrum M(z) > 0 on $\mathbb{T}_N \coloneqq \{e^{j2\pi n/N} \mid \overline{n=0,\ldots,N-1}\}$
- 2: **Output:** Causal spectral factor U(z) of M(z) > 0 on \mathbb{T}_N
- 3: Compute the cepstrum $\Lambda(z) \leftarrow \log(M(z))$ on $z \in \mathbb{T}_N$.
- 4: Compute the inverse DFT $\lambda_k \leftarrow \text{IDFT}(\Lambda(z))$ for $k = 0, \dots, N-1$
- 5: Compute the spectral factor for $z_n = e^{j2\pi n/N}$

$$U(z_n) \leftarrow \exp\left(\frac{1}{2}\lambda_0 + \sum_{k=1}^{N/2-1} \lambda_k z_n^{-k} + \frac{1}{2}(-1)^n \lambda_{N/2}\right), \quad n = 0, \dots, N-1$$

E.6 Implementation of Bisection Method

To find the optimal parameter γ_k that solves $\text{Tr}\left[((I - \gamma_k^{-1}\mathcal{G}_k)^{-1} - I)^2\right] = \rho^2$ in the Frank-Wolfe update (21), we use a bisection algorithm. The pseudo code for the bisection algorithm can be found in Algorithm 3. We start off with two guesses of γ *i.e.* $(\gamma_{left}, \gamma_{right})$ with the assumption that the optimal γ lies between the two values (without loss of generality).

Algorithm 3 Bisection Algorithm

- 1: Input: $\gamma_{right}, \gamma_{left}$
- 2: Compute the gradient at γ_{right} : $grad_{\gamma_{right}}$
- 3: while $|\gamma_{right} \gamma_{left}| > \epsilon$ do
- 4: Calculate the midpoint γ_{mid} between γ_{left} and γ_{right}
- 5: Compute the gradient at γ_{mid}
- 6: **if** the gradient at γ_{mid} is zero **then**
- 7: **return** γ_{mid} {Root found}
- 8: **else if** the gradient at γ_{mid} is positive **then**
- 9: Update γ_{right} to γ_{mid}
- 10: else
- 11: Update γ_{left} to γ_{mid}
- 12: **end if**

```
13: end while
```

14: **return** the average of γ_{left} and γ_{right} {Approximate root}

E.7 Proof of Theorem 4.4

Our proof of convergence follows closely from the proof technique used in [88]. In particular, since the unit circle is discretized and the computation of the gradients $G_k(z)$ are approximate, the linear suboptimal problem is solved up to an approximation, δ_N , which depends on the problem parameters, and the discretization level N. Namely,

$$\operatorname{Tr}(\nabla \Phi(\mathcal{M}_k)\widetilde{\mathcal{M}}_{k+1}) \ge \sup_{\mathcal{M}\in\Omega_{\rho}} \operatorname{Tr}(\nabla \Phi(\mathcal{M}_k)\mathcal{M}) - \delta_N$$
(132)

where

$$\Omega_{\rho} \coloneqq \{ \mathcal{M} \succ 0 \mid \operatorname{Tr}(\mathcal{M} - 2\sqrt{\mathcal{M}} + \mathcal{I}) \le \rho^2 \},$$
(133)

Therefore, using Theorem 1 of [88], we obtain

$$\Phi(\mathcal{M}_{\star}) - \Phi(\mathcal{M}_k) \le \frac{2\kappa}{k+2}(1+\delta_N).$$
(134)

where

$$\kappa \coloneqq \sup_{\substack{\mathcal{M}, \widetilde{\mathcal{M}} \in \Omega_{\rho} \\ \eta \in [0,1] \\ \mathcal{M}' = \mathcal{M} + \eta(\widetilde{\mathcal{M}} - \mathcal{M})}} \frac{2}{\eta^{2}} \left(\operatorname{Tr}(\mathcal{M}' \nabla \Phi(\mathcal{M})) - \Phi(\mathcal{M}') \right).$$
(135)

E.8 Implementation of Rational Approximation

We present the pseudocode of RationalApproximation.

Algorithm 4 Rational Approximation

- 1: Input: Scalar positive spectrum M(z) > 0 on $\mathbb{T}_N := \{e^{j2\pi n/N} \mid n = 0, \dots, N-1\}$, and a small positive scalar ϵ
- 2: **Output:** Causal rational filter K(z) on \mathbb{T}_N
- 3: Get P(z), Q(z) by solving the convex optimization in (23), for fixed ϵ , given M(z)
- 4: Get the rational spectral factors of P(z), Q(z), which are $S_P(z), S_Q(z)$ using the canonical Factorization method in [91]
- 5: Get $U^r(z)$, the rational spectral factor of M(z), as $S_P(z)/S_Q(z)$
- 6: Get K(z) from the formulation in (25), (153)

E.9 Proof of Theorem 4.6

We write the DR estimator, $K(e^{j\omega})$, as a sum of causal functions:

$$K(e^{j\omega}) = U^{-1} \{ UK_0 \Delta \}_+ \Delta^{-1}$$
(136)

$$= U^{-1} (U\{K_0 \Delta\}_+ + \{U\{K_0 \Delta\}_-\}_+) \Delta^{-1}$$
(137)

$$= \{K_0\Delta\}_+\Delta^{-1} + U^{-1}\{U\{K_0\Delta\}_-\}_+\Delta^{-1}$$
(138)

where we drop the dependence of Δ , K_0 and U on $e^{j\omega}$.

Given the spectral factor $U(e^{j\omega})$ in rational form as $U(e^{j\omega}) = \tilde{D}^{1/2}(I + \tilde{C}(e^{j\omega}I - \tilde{A})^{-1}\tilde{B})$, its inverse is given by:

$$U^{-1}(e^{j\omega}) = (I - \tilde{C}(e^{j\omega}I - (\tilde{A} - \tilde{B}\tilde{C}))^{-1}\tilde{B})\tilde{D}^{-1/2}$$
(139)

From the above, we have:

$$\{K_0\Delta\}_{-} = T(z) = C_s P A_P^* (z^{-1}I - A_P^*)^{-1} C_y^* (I + C_y P C_y^*)^{-*/2}$$
(140)

Multiplying the above equation with U, and taking its causal part, we get:

$$\{U\{\Delta K_0\}_-\}_+ = \{\tilde{D}^{1/2}C_sPA_P^*(z^{-1}I - A_P^*)^{-1}C_y^*(I + C_yPC_y^*)^{-*/2} + \tilde{D}^{1/2}\tilde{C}(e^{j\omega}I - \tilde{A})^{-1}\tilde{B}C_sPA_P^*(z^{-1}I - A_P^*)^{-1}C_y^*(I + C_yPC_y^*)^{-*/2}\}_+$$
(141)

Given that the term $\tilde{D}^{1/2}C_sPA_P^*(z^{-1}I - A_P^*)^{-1}C_y^*(I + C_yPC_y^*)^{-*/2}$ is strictly anticausal, and considering the matrix U_{ly} which solves the lyapunov equation: $\tilde{A}U_{ly}A_P^* + \tilde{B}C_sPA_P^* = U_{ly}$, we get $\{U\{K_0\Delta\}_+\}_+$ as:

$$\{U\{\Delta K_0\}_-\}_+ = \{\tilde{D}^{1/2}\tilde{C}\left((zI - \tilde{A})^{-1}\tilde{A}U_{ly} + U_{ly}A_P^*(z^{-1}I - A_P^*)^{-1} + U_{ly}\right)C_y^*(I + C_yPC_y^*)^{-*/2}\}_+$$
(142)

$$= \tilde{D}^{1/2} \tilde{C} \left((zI - \tilde{A})^{-1} \tilde{A} + I \right) U_{ly} C_y^* (I + C_y P C_y^*)^{-*/2}$$
(143)

$$= z\tilde{D}^{1/2}\tilde{C}(zI - \tilde{A})^{-1}U_{ly}C_y^*(I + C_yPC_y^*)^{-*/2}$$
(144)

Now, multiplying equation (144) by the inverse of U (139), we get:

$$U^{-1}\{U\{K_0\Delta\}_-\}_+ = z(I + \tilde{C}(e^{j\omega}I - \tilde{A})^{-1}\tilde{B})^{-1}\tilde{C}(zI - \tilde{A})^{-1}U_{ly}C_y^*(I + C_yPC_y^*)^{-*/2}$$
(145)
$$= z\tilde{C}(I + (zI - \tilde{A})^{-1}\tilde{E}\tilde{C})^{-1}(zI - \tilde{A})^{-1}U_{ly}C_y^*(I + C_yPC_y^*)^{-*/2}$$
(146)

$$= z\tilde{C}(I + (zI - \tilde{A})^{-1}\tilde{B}\tilde{C})^{-1}(zI - \tilde{A})^{-1}U_{ly}C_y^*(I + C_yPC_y^*)^{-*/2}$$
(146)
$$= z\tilde{C}(zI - \tilde{A}_P)^{-1}U_{ly}C_y^*(I + C_yPC_y^*)^{-*/2}$$
(147)

$$= z\hat{C}(zI - \hat{A}_P)^{-1}U_{ly}C_y^*(I + C_yPC_y^*)^{-*/2}$$
(147)

$$= \tilde{C}(I + \tilde{A}_P(zI - \tilde{A}_P)^{-1})U_{ly}C_y^*(I + C_yPC_y^*)^{-*/2}$$
(148)

(149)

where $\tilde{A}_P = \tilde{A} - \tilde{B}\tilde{C}$.

The inverse of Δ is given by $\Delta^{-1}(z) = (I + C_y P C_y^*)^{-1/2} (I - C_y (zI - A_P)^{-1} K_P)$, and we already showed that $\{K_0\Delta\}_+ = C_s(zI - A)^{-1}APC_y^*(I + C_yPC_y^*)^{-*/2} + C_sPC_y^*(I + C_yPC_y^*)^{-*/2}$. Then we can get the 2 terms of equation (138):

$$\{K_0\Delta\}_+\Delta^{-1} = C_s P C_y^* (I + C_y P C_y^*)^{-1} + C_s \left(I - P C_y^* (I + C_y P C_y^*)^{-1} C_y\right) (zI - A_P)^{-1} K_P$$
(150)

and

$$U^{-1}\{U\{K_{0}\Delta\}_{-}\}_{+}\Delta^{-1} = \left(\tilde{C}U_{ly}C_{y}^{*}(I+C_{y}PC_{y}^{*})^{-*/2} + \tilde{C}\tilde{A}_{P}(zI-\tilde{A}_{P})^{-1}U_{ly}C_{y}^{*}(I+C_{y}PC_{y}^{*})^{-*/2}\right) \times \left((I+C_{y}PC_{y}^{*})^{-1/2} - (I+C_{y}PC_{y}^{*})^{-1/2}C_{y}(zI-A_{P})^{-1}K_{P}\right)$$
(151)
$$= \tilde{C}\tilde{A}_{P}(zI-\tilde{A}_{P})^{-1}U_{ly}C_{y}^{*}(I+C_{y}PC_{y}^{*})^{-1}\left(I-C_{y}(zI-A_{P})^{-1}K_{P}\right)$$
(152)
$$-\tilde{C}U_{ly}C_{y}^{*}(I+C_{y}PC_{y}^{*})^{-1}C_{y}(zI-A_{P})^{-1}K_{P}$$

Finally, summing equations (150) and (151), we get the controller $K(e^{j\omega})$ in its rational form:

$$K(e^{j\omega}) = \begin{bmatrix} \tilde{C}\tilde{A}_P & -C_s + C_s P C_y^* (I + C_y P C_y^*)^{-1} C_y + \tilde{C} U_{ly} C_y^* (I + C_y P C_y^*)^{-1} C_y \end{bmatrix}$$
(153)

$$\times \left(zI - \begin{bmatrix} A_P & U_{ly}C_y^*(I + C_yPC_y^*)^{-1}C_y \\ 0 & A_P \end{bmatrix} \right)^{-1} \begin{bmatrix} U_{ly}C_y^*(I + C_yPC_y^*)^{-1} \\ -K_P \end{bmatrix}$$
(154)

$$+\tilde{C}U_{ly}C_y^*(I+C_yPC_y^*)^{-1}+C_sPC_y^*(I+C_yPC_y^*)^{-1}$$
(155)

which can be explicitly rewritten as in equation (25), where $\tilde{F}, \tilde{G}, \tilde{H}$ and \tilde{L} are defined accordingly.
