Abstract

In this paper, we investigate $f(Q)$ gravity (Q represents the non-metricity) to explore its cosmological implications of the two non-interacting dark energy models. We use the correspondence scenario to find the pilgrim and generalized ghost pilgrim dark energy $f(Q)$ gravity models for a Friedmann-Robertson-Walker universe with pressureless matter and a power-law scale factor. The reconstructed models explain the observed rapid expansion of the universe using astronomical observations. We also examine the physical properties of the model, including its equation of state parameter, $(\omega_D - \omega'_D)$ and $(r-s)$ -planes and the squared speed of sound. It is found that our results are consistent with the interacting pilgrim dark energy model in the same gravity.

Keywords: Cosmological evolution, Dark energy, $f(Q)$ gravity.

1 Introduction

Numerous characteristics of the universe have been described by the general theory of relativity (GR) using a variety of observational data. Recent astrophysical findings such as Supernovae type-Ia [1], large-scale structure [2] combined with the baryon acoustic oscillations [3] and cosmic microwave background radiations [4] indicate that the universe is currently experiencing accelerated expansion. There is a strong evidence suggesting that this universe is mainly defined by the mysterious components, i.e., dark matter (DM) and dark energy (DE). In GR, adding a cosmological constant into the field equations helps us to better understand the mysterious properties of DE. However, this constant introduces challenges like the fine-tuning and coincidence problems [5]. Several modified gravity theories (MGTs) have been suggested to address the complexities in GR. There are two established approaches to define the cosmic acceleration. One significant aspect is the introduction of DE with large negative pressure in GR [2] and the other is the extension and modification of the GR action. In recent years, experiments have shown that MGTs effectively describe early phenomena such as inflation and late-period acceleration.

In order to investigate the characteristics of DE, various efforts have been made such as modification of gravity and DE models. Dynamical DE models are attained by altering the matter component, incorporating entities such as phantom, quintessence, Chaplygin gas, among others. Various models have been developed based on energy densities to comprehend various stages of the cosmic evolution. According to recent research, this can be explained by adding a new degree of freedom or by assuming a new parameter. The new DE model may have numerous unfamiliar characteristics and can give rise to fresh challenges in existing literature. Our initial approach is to address the DE problem without bringing in additional degrees of freedom beyond those already recognized. A new category of models called ghost DE (GDE) has attracted considerable interest. According to this theory, the Veneziano ghost field is believed to be accountable for the recent expansion of the universe [6]. The energy density of the GDE model is expressed as $\rho_D = \alpha H$, where the constant α has dimensions of $[energy]^3$. Cai et al. [7] concluded that incorporating the second-order term in the GDE model is crucial for precisely depicting the dynamics of the early universe. This modification characterizes the model for GGDE as $\rho_D = \alpha H + \beta H^2$, where β represents another constant with dimensions of $[energy]^2$.

Wei [8] proposed the pilgrim DE (PDE), emphasizing a phantom-like universe to avoid the formation of black holes. The PDE model is given as

$$\rho_D = \alpha(H)^\psi, \quad \psi \leq 2, \quad (1)$$

ψ is a dimensionless constant. The MGTs have also been used to explore the cosmic implications of the GGPDE model. The generalized ghost PDE (GGPDE) model is the commonly accepted PDE extension of GGDE. The energy density of the GGPDE model can be described by the following equation

$$\rho_D = (\alpha H + \beta H^2)^\psi. \quad (2)$$

Sharif and Jawad [9] explored the proposal of PDE in an interacting framework with CDM using three cutoffs. Sharif and Zubair [10] formulated a PDE model in $f(R)$ gravity using various IR cut-offs and reconstructed $f(R)$ model to demonstrate its unique behavior in future cosmic evolution. Sharif and Rani [11] investigated the mysterious nature of PDE in $f(T)$ gravity (T represents the torsion scalar) using Hubble horizon as an IR-cutoff and investigated phase planes as well as cosmological parameters. Chattopadhyay et al. [12] studied the puzzling characteristics of PDE in $f(T, T_G)$ gravity (T_G denotes the teleparallel equivalent of the Gauss-Bonnet term) and found an extremely active phantom-like behavior, which is essential for preventing black hole formation. Sharif and Nazir [13] investigated GGPDE to examine black hole creation in the context of $f(T, T_G)$ gravity. Sharif and Nawazish [14] studied various standard cosmological parameters and stability criteria in GGPDE $f(R)$ gravity model. Sharif and Saba [15] analyzed the cosmological behavior of the reconstructed PDE and GGPDE models using cosmic diagnostic parameters, phase planes and the squared speed of sound (ν_s^2) in $f(G, \mathcal{T})$ gravity (\mathcal{T} is trace of the energy-momentum tensor (EMT)).

General relativity is described through Riemannian geometry which requires the affine connection of spacetime manifold to adhere the metric compatibility known as the Levi-Civita connection [16]. A manifold can support different options for affine connection and different connections could result in various representations of gravity. As a result, they may provide varying viewpoints and understanding of the phenomenon. The GR specifies that the Levi-Civita connection requires both the non-metricity Q and torsion T to be zero, while keeping the curvature as a fundamental geometrical object. By relaxing these constraints, it is possible to develop the theories of gravity rooted in non-Riemannian geometry, where curvature, torsion and

non-metricity can all be non-zero. The teleparallel equivalent of GR (TEGR) [17, 18] can be stated by selecting a connection that allows non-zero torsion but does not require curvature or non-metricity. By considering a flat space-time without torsion but with non-zero non-metricity, one could develop the symmetric teleparallel formulation of GR (STGR) [19]-[25].

Researchers are much motivated in exploring the non-Riemannian geometry, for example, $f(Q)$ theory. The motivation behind this theory is to examine its theoretical significance, consistency with observed data and importance in the study of cosmic phenomena. This theory examines theoretical implications derived from cosmic domains and empirical observations. Lazkoz et al. [26] examined the limitations of $f(Q)$ gravity through the utilization of polynomial expressions in relation to red-shift. They also studied the energy conditions for two different models in this gravity. Bajardi et al. [27] derived the cosmic wave function using Hamiltonian formalism in this framework. Shekh [28] conducted a dynamic analysis of the holographic DE model within the same theoretical framework. Frusciante [29] presented a specific model in this gravity which exhibited similarities to the Λ CDM model on a foundational level. Lymperis [30] investigated the cosmic evolution in the presence and absence of cosmological constant Λ with phantom DE. Dimakis et al. [31] studied cosmic evolution with phantom DE both in the presence and absence of the cosmological constant. Khylllep et al. [32] examined the universe accelerated expansion using power-law and exponential models of $f(Q)$ theory. In a recent paper [33], we have explored the cosmography of GGDE in the same gravity. Sharif et al. [34] explored the idea of a cosmological bounce in non-Riemannian geometry.

This paper explores the correspondence scheme involving PDE and GG-PDE models by using reconstruction technique within $f(Q)$ gravity. The structure of the paper is as follows. Section **2** discusses the FRW universe with fluid sources non-interacting between DM and DE and the field equation of $f(Q)$ gravity. Sections **3** and **4** provide a discussion on cosmographic observations using cosmic diagnostic parameters and phase planes for the reconstructed PDE and GGPDE $f(Q)$ gravity models, respectively. Finally, we present our conclusions in section **5**.

2 FRW Universe Model and $f(Q)$ Gravity

The line element that characterizes a spatially homogeneous and isotropic model of the universe is expressed as

$$ds^2 = -dt^2 + a^2(t)(dx^2 + dy^2 + dz^2), \quad (3)$$

where a scale factor is denoted by $a(t)$. The total EMT for DE and DM is

$$\hat{\mathcal{T}}_{\psi\gamma} = \mathcal{T}_{\psi\gamma} + \tilde{\mathcal{T}}_{\psi\gamma}, \quad (4)$$

where the EMTs for pressureless DM and DE are denoted by $\mathcal{T}_{\psi\gamma}$ and $\tilde{\mathcal{T}}_{\psi\gamma}$, defined as $\mathcal{T}_{\psi\gamma} = (\rho_{\mathbf{m}})u_{\psi}u_{\gamma}$ and $\tilde{\mathcal{T}}_{\psi\gamma} = (\rho_D + p_D)u_{\psi}u_{\gamma} + p_D g_{\psi\gamma}$, respectively, u_{γ} is the four velocity, p_D denotes the pressure of DE, and $\rho_{\mathbf{m}}$ and ρ_D indicate the energy densities of DM and DE, respectively. The following expressions denote the energy densities in fractional form for DE and DM as

$$\Omega_{\mathbf{m}} = \frac{\rho_{\mathbf{m}}}{\rho_{cr}} = \frac{\rho_{\mathbf{m}}}{3H^2}, \quad \Omega_D = \frac{\rho_D}{\rho_{cr}} = \frac{\rho_D}{3H^2}, \quad (5)$$

implying that 1 can be expressed as the sum of Ω_D and $\Omega_{\mathbf{m}}$, ρ_{cr} is the critical density. The continuity equations for the non-interacting DM and DE are

$$\dot{\rho}_{\mathbf{m}} + 3H(\rho_{\mathbf{m}}) = 0, \quad (6)$$

$$\dot{\rho}_D + 3H(\rho_D + p_D) = 0. \quad (7)$$

We assume the scale factor in power-law form as

$$a(t) = a_0 t^m, \quad (8)$$

where m and a_0 are arbitrary constants and a_0 has a current value of 1. The power-law form simplifies the differential equations governing cosmological dynamics, making analytical solutions more accessible. This aids in understanding the qualitative behavior of the universe's expansion and the evolution of DE. When $m > 1$, the scale factor indicates accelerated expansion, aligning with current observations of the universe's acceleration. By examining how m influences the universe's expansion and comparing it with observational data, these models can offer deeper insights into the nature of DE and the fundamental properties of gravity. The parameter m is crucial for determining how quickly the universe transitions between different

phases of expansion, such as from decelerated to accelerated expansion. This is crucial for matching the model to different cosmological epochs, including the matter-dominated era and the dark energy-dominated era. Fitting the power-law scale factor to cosmological data allows researchers to test the compatibility of the PDE and GGPDE $f(Q)$ models with observations. This helps in validating or constraining these models.

The values of H , its derivative and the non-metricity in terms of this scale factor are given as follows

$$H = \frac{\dot{a}}{a} = \frac{m}{t}, \quad \dot{H} = -\frac{m}{t^2}, \quad Q = 6H^2 = 6\frac{m^2}{t^2}, \quad (9)$$

where, dot represents derivative with respect to t . Integrating Eq.(6), we have

$$\rho_{\mathbf{m}} = \xi(a)^{-3} = \xi(t^m)^{-3}, \quad (10)$$

where ξ is an integration constant.

The action for $f(Q)$ gravity is expressed as [22]

$$S = \int \left(\frac{1}{2k} f(Q) + \mathcal{L}_{\mathbf{m}} \right) \sqrt{-g} d^4x, \quad (11)$$

where g represents determinant of the metric tensor, $\mathcal{L}_{\mathbf{m}}$ stands for the matter Lagrangian density and Q is described as

$$Q = -g^{\gamma\psi} (\mathbb{L}^{\mu}_{\nu\gamma} \mathbb{L}^{\nu}_{\psi\mu} - \mathbb{L}^{\mu}_{\nu\mu} \mathbb{L}^{\nu}_{\gamma\psi}). \quad (12)$$

The Levi-Civita connection in symmetric connections can be written using the deformation tensor as $\Gamma^{\mu}_{\nu\varsigma} = -\mathbb{L}^{\mu}_{\nu\varsigma}$, where

$$\mathbb{L}^{\mu}_{\nu\varsigma} = -\frac{1}{2} g^{\mu\lambda} (\nabla_{\varsigma} g_{\nu\lambda} + \nabla_{\nu} g_{\lambda\varsigma} - \nabla_{\lambda} g_{\nu\varsigma}). \quad (13)$$

The traces of the Q tensor are defined as

$$Q_{\mu} = Q_{\mu}^{\psi}, \quad \tilde{Q}_{\mu} = Q^{\psi}_{\mu\psi}. \quad (14)$$

The superpotential can be written as

$$\mathbb{P}^{\mu\psi\gamma} = \frac{1}{4} \left[-Q^{\mu\psi\gamma} + Q^{\psi\mu\gamma} + Q^{\gamma\mu\psi} + Q^{\psi\mu\gamma} - \tilde{Q}_{\mu} g^{\psi\gamma} + Q^{\mu} g^{\psi\gamma} \right]. \quad (15)$$

Consequently, the relation for Q becomes [23]

$$Q = -Q_{\mu\gamma\psi} \mathbb{P}^{\mu\gamma\psi} = -\frac{1}{4}(-Q^{\mu\psi\rho} Q_{\mu\psi\rho} + 2Q^{\mu\psi\rho} Q_{\rho\mu\psi} - 2Q^\rho \tilde{Q}_\rho + Q^\rho Q_\rho). \quad (16)$$

The corresponding field equations of $f(Q)$ gravity take the form

$$\frac{-2}{\sqrt{-g}} \nabla_\gamma (f_Q \sqrt{-g} P^\mu_{\gamma\psi}) - \frac{1}{2} f g_{\gamma\psi} - f_Q (P_{\gamma\mu\nu} Q_\psi^{\mu\nu} - 2Q^{\mu\nu}{}_\gamma P_{\mu\nu\psi}) = k^2 T_{\gamma\psi}, \quad (17)$$

where $f_Q = \frac{\partial f(Q)}{\partial Q}$. The modified Friedmann equations for $f(Q)$ gravity are

$$2\dot{H} + 3H^2 = p_D + p_m, \quad 3H^2 = \rho_D + \rho_m, \quad (18)$$

where

$$\rho_D = -6H^2 f_Q + \frac{f}{2}, \quad (19)$$

$$p_D = 2f_Q \dot{H} + 2H f_{QQ} + 6H^2 f_Q - \frac{f}{2}. \quad (20)$$

3 Reconstruction of PDE $f(Q)$ Model

In this section, we use a method to reconstruct the PDE $f(Q)$ model by equating the corresponding densities. Using Eqs.(1) and (19), we have

$$\frac{f}{2} - 6H^2 f_Q = \alpha H^\psi. \quad (21)$$

The PDE model often involves modifications to standard gravitational theories to accommodate its effects on cosmic dynamics. This equation represents the first-order linear differential equation in Q and its solution is obtained as

$$f(Q) = \frac{6^{-\frac{\psi}{2}} \left(c\sqrt{Q} 6^{\psi/2} (\psi - 1) - 2\alpha Q^{\psi/2} \right)}{\psi - 1}. \quad (22)$$

In terms of t , this model can be obtained by substituting Eq.(9) in (22) as

$$f(Q) = \frac{\sqrt{6}c(\psi - 1) \sqrt{\frac{m^2}{t^2}} - 2\alpha \left(\frac{m^2}{t^2} \right)^{\psi/2}}{\psi - 1}. \quad (23)$$

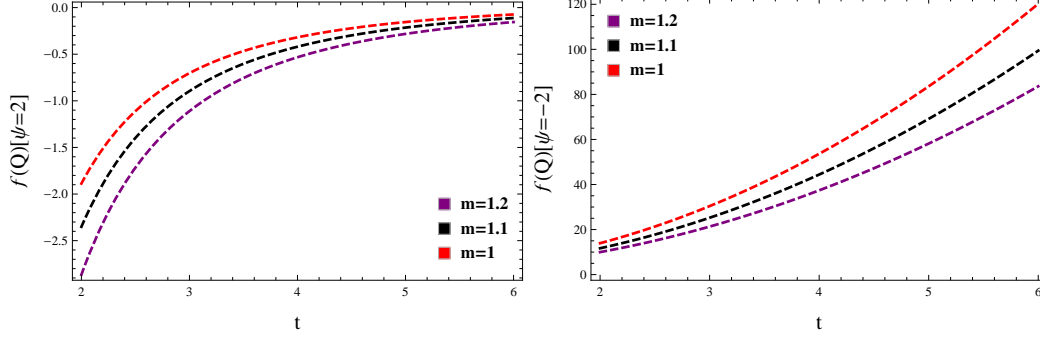

Figure 1: Graphs show the relationship between $f(Q)$ ($\psi = \pm 2$) and t .

Figure 1 shows the behavior of the reconstructed PDE $f(Q)$ gravity model for three various values $m = 1.2, 1.1, 1$, indicating decrease with increasing values of t for $\psi = 2$. On the other hand, for $\psi = -2$, $f(Q)$ increases with increasing values of t . The values of ρ_D and p_D are found by substituting Eq.(22) in (19) and (20) as

$$\begin{aligned} \rho_D &= \alpha 6^{-\frac{\psi}{2}} Q^{\psi^2} + c, \\ p_D &= \frac{1}{Q^2(\psi - 1)} \left[2^{-\frac{\psi}{2}-1} 3^{-\frac{\psi}{2}} \left(cQ^{\frac{3}{2}} 2^{\frac{\psi}{2}+1} 3^{\frac{\psi}{2}} (\psi - 1) (\dot{H} + 3H^2) \right. \right. \\ &\quad - cH\sqrt{Q} 6^{\frac{\psi}{2}} (\psi - 1) + cQ^{\frac{5}{2}} 6^{\frac{\psi}{2}} (\psi - 1) - 4\alpha\psi(\dot{H} + 3H^2) Q^{\frac{\psi}{2}+1} \\ &\quad \left. \left. - 2\alpha H(\psi - 2)\psi Q^{\frac{\psi}{2}} - 2\alpha Q^{\frac{\psi}{2}+2} \right) \right]. \end{aligned}$$

Inserting Eq.(9) into the above equations, we can represent them in the form of a power-law as

$$\begin{aligned} \rho_D &= \alpha \left(\frac{m^2}{t^2} \right)^{\psi/2} + c, \\ p_D &= -\frac{1}{72m^3(\psi - 1)} \left[-12m^2 \left(2\alpha\psi \left(\frac{m^2}{t^2} \right)^{\psi/2} - \sqrt{6}c(\psi - 1) \sqrt{\frac{m^2}{t^2}} \right) \right. \\ &\quad + t^3 \left(\sqrt{6}c(\psi - 1) \sqrt{\frac{m^2}{t^2}} + 2\alpha(\psi - 2)\psi \left(\frac{m^2}{t^2} \right)^{\psi/2} \right) \\ &\quad \left. + \left(\alpha(\psi + 1) \left(\frac{m^2}{t^2} \right)^{\psi/2} - \sqrt{6}c(\psi - 1) \sqrt{\frac{m^2}{t^2}} \right) 72m^3 \right]. \end{aligned}$$

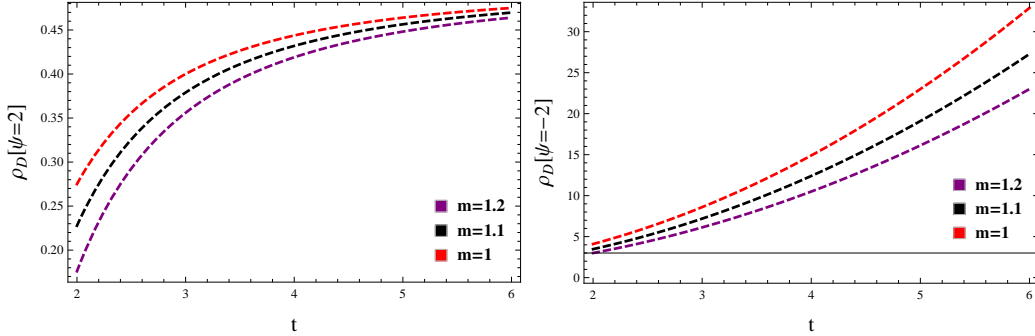

Figure 2: Graphs of ρ_D ($\psi = \pm 2$) against t .

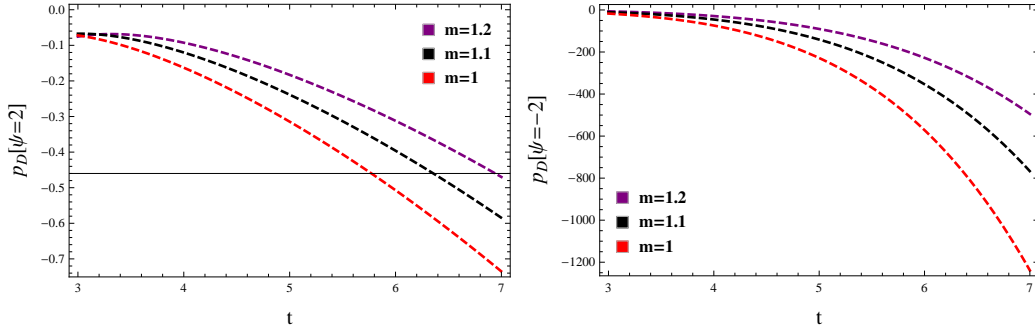

Figure 3: Graphs of p_D ($\psi = \pm 2$) versus t .

Figures **2** and **3** show the behavior of ρ_D and p_D over time. The energy density ρ_D exhibits a positive trend, while p_D illustrates a negative pattern for all values of m and ψ , consistent with the behavior expected for DE.

Now, we illustrate the behavior of different cosmological parameters, such as the equation of state parameter (EoS) parameter and phase planes. We also analyze the stability of this model. The EoS is defined by the ratio ($\omega_D = \frac{p_D}{\rho_D}$). For different forms of matter and energy, ω_D takes on different values. For matter-dominated regions, i.e., non-relativistic matter (dust) ($\omega_D = 0$), radiation ($\omega_D = \frac{1}{3}$) and stiff matter ($\omega_D = 1$). For DE models, the EoS parameter helps in understanding the nature of DE, whether it behaves like a vacuum, quintessence and phantom energy. For instance, $\omega_D = -1$ corresponds to a vacuum, while $\omega_D < -1$ indicates phantom energy,

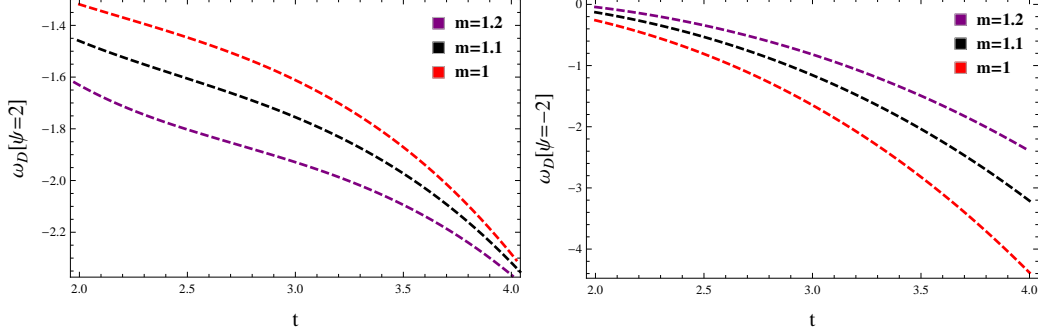

Figure 4: Plots of ω_D ($\psi = \pm 2$) against t .

$-1 < \omega_D < -\frac{1}{3}$ leads to quintessence phase. Thus we have

$$\begin{aligned} \omega_D = & -\frac{1}{72m^3(\psi-1)\left(\alpha t^{3m}\left(\frac{m^2}{t^2}\right)^{\psi/2} + \xi\right)} \left[t^{3m} \left(-12m^2 \left(2\alpha\psi \left(\frac{m^2}{t^2} \right)^{\psi/2} \right. \right. \right. \\ & - \left. \left. \sqrt{6}c(\psi-1)\sqrt{\frac{m^2}{t^2}} \right) + t^3 \left(\sqrt{6}c(\psi-1)\sqrt{\frac{m^2}{t^2}} + 2\alpha(\psi-2)\psi \left(\frac{m^2}{t^2} \right)^{\frac{\psi}{2}} \right) \right. \\ & \left. \left. + 72m^3 \left(\alpha(\psi+1) \left(\frac{m^2}{t^2} \right)^{\psi/2} - \sqrt{6}c(\psi-1)\sqrt{\frac{m^2}{t^2}} \right) \right) \right]. \end{aligned}$$

Figure 4 shows the EoS parameter for three distinct values of m , indicating $\omega_D < -1$. This suggests that the model incorporates phantom field DE for both $\psi = 2$ and $\psi = -2$, and fulfills the PDE phenomenon.

The $(\omega_D - \omega'_D)$ -plane [36] (prime means derivative with respect to Q) categorizes different DE scenarios into distinct regions such as thawing ($\omega_D < 0$, $\omega'_D > 0$) and freezing ($\omega_D < 0$, $\omega'_D < 0$), based on their evolutionary trajectories. Here we have

$$\begin{aligned} \omega'_D = & \frac{1}{432\sqrt{6}m^5(\psi-1)\left(\alpha t^{3m}\left(\frac{m^2}{t^2}\right)^{\psi/2} + \xi\right)^2} \left[t^{3m+2} \left(-12m^2 \left(t^{3m} \left(2\sqrt{6} \right. \right. \right. \right. \\ & \times \left. \left. \alpha^2\psi \left(\frac{m^2}{t^2} \right)^\psi - 3\alpha c(\psi^2-1) \left(\frac{m^2}{t^2} \right)^{\frac{\psi+1}{2}} \right) - \xi \left(3c(\psi-1)\sqrt{\frac{m^2}{t^2}} + \sqrt{6} \right) \right. \end{aligned}$$

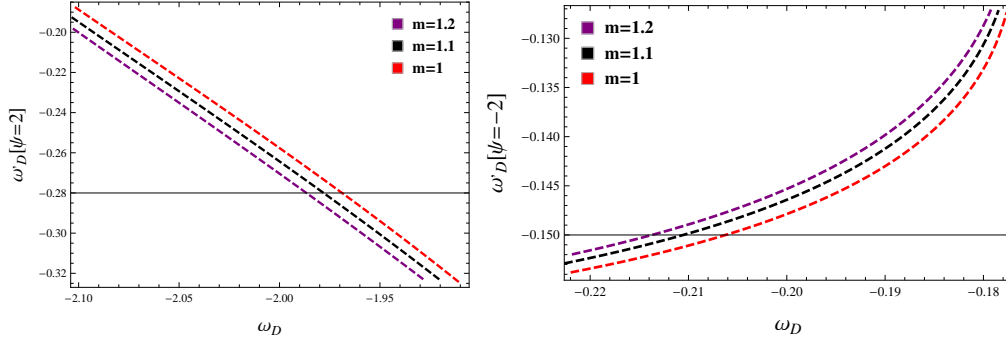

Figure 5: Graphs of ω'_D ($\psi = \pm 2$) against ω_D .

$$\begin{aligned}
& \times \alpha(\psi - 2)\psi\left(\frac{m^2}{t^2}\right)^{\frac{\psi}{2}}) + t^3\left(\alpha t^{3m}\left(\frac{m^2}{t^2}\right)^{\frac{\psi}{2}}\left(3c(\psi^2 + 2\psi - 3)\sqrt{\frac{m^2}{t^2}}\right.\right. \\
& + 4\sqrt{6}\alpha(\psi - 2)\psi\left(\frac{m^2}{t^2}\right)^{\frac{\psi}{2}}) - \xi\left(\sqrt{6}\alpha\psi\left(\psi^2 - 6\psi + 8\right)\left(\frac{m^2}{t^2}\right)^{\frac{\psi}{2}} - 9c\right. \\
& \times (\psi - 1)\sqrt{\frac{m^2}{t^2}}) + 36\alpha m^3\psi\left(\frac{m^2}{t^2}\right)^{\psi/2}\left(2t^{3m}\left(\sqrt{6}\alpha\left(\frac{m^2}{t^2}\right)^{\psi/2} - 3c\right.\right. \\
& \left.\left.\times (\psi - 1)\sqrt{\frac{m^2}{t^2}} - \sqrt{6}\xi(\psi - 1)\right)\right)\left. \right].
\end{aligned}$$

Figure 5 indicates that $\omega_D < 0$, $\omega'_D < 0$ for all values of m and PDE parameters, demonstrating the existence of the freezing region. The $(r - s)$ -plane [37] helps to distinguish between different models of the universe expansion. In this plane, trajectories falling within the range $(r < 1)$ and $(s > 0)$ represent epochs dominated by phantom and quintessence DE, respectively. Conversely, trajectories characterized by $(r > 1)$ and $(s < 0)$ correspond to the Chaplygin gas model. The two dimensionless parameters for the $(r - s)$ -plane are given as

$$r = \frac{\ddot{a}}{aH^3}, \quad s = \frac{r - 1}{3(q - \frac{1}{2})}.$$

The values of r and s are given in Appendix A. Figure 6 demonstrates the Chaplygin gas model ($r > 1$ and $s < 0$) for various values of m and PDE parameter.

The behavior of the ν_s^2 parameter is crucial in cosmological models, dictating the stability of cosmic structures. When the ν_s^2 remains positive, this

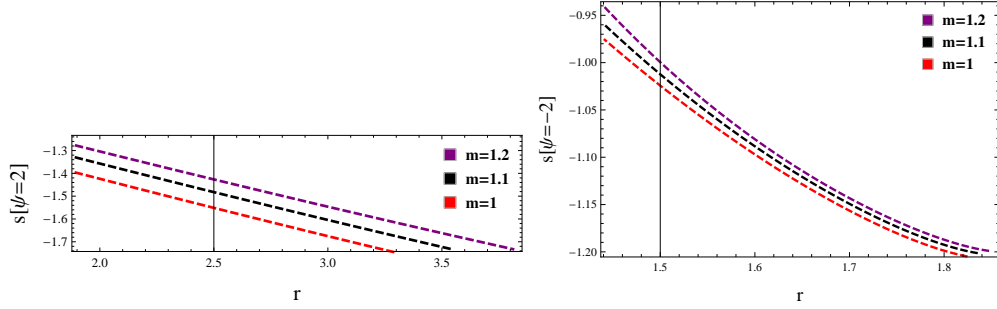

Figure 6: Plots of r ($\psi = \pm 2$) versus s .

indicates stability, while its negative value signals instability. This is given as

$$\nu_s^2 = \frac{\dot{\rho}_D}{\rho_D} = \frac{\rho_D}{\dot{\rho}_D} \omega'_D + \omega_D,$$

and hence

$$\begin{aligned} \nu_s^2 = & \frac{1}{5184\alpha m^6(\psi-1)^2\psi\left(\alpha t^{3m}\left(\frac{m^2}{t^2}\right)^{\psi/2} + \xi\right)^2} \left[t^{3m}\left(\frac{m^2}{t^2}\right)^{-\psi/2} \left(-12m^2 \right. \right. \\ & \times \left(2\alpha\psi\left(\frac{m^2}{t^2}\right)^{\psi/2} - \sqrt{6}c(\psi-1)\sqrt{\frac{m^2}{t^2}} \right) + t^3\left(\sqrt{6}c(\psi-1)\sqrt{\frac{m^2}{t^2}} + 2\alpha \right. \\ & \times \left. \left. (\psi-2)\psi\left(\frac{m^2}{t^2}\right)^{\psi/2} \right) + \left(\alpha(\psi+1)\left(\frac{m^2}{t^2}\right)^{\psi/2} - \sqrt{6}c(\psi-1)\sqrt{\frac{m^2}{t^2}} \right) \right. \\ & \times \left. 72m^3 \right) \left(-12m^2 \left(\xi \left(-\sqrt{6}c(\psi-1)\sqrt{\frac{m^2}{t^2}} - 2\alpha(\psi-2)\psi\left(\frac{m^2}{t^2}\right)^{\psi/2} \right) \right. \right. \\ & + \left. t^{3m} \left(4\alpha^2\psi\left(\frac{m^2}{t^2}\right)^\psi - \sqrt{6}\alpha c(\psi^2-1)\left(\frac{m^2}{t^2}\right)^{\frac{\psi+1}{2}} \right) \right) + t^3\left(\alpha\left(\frac{m^2}{t^2}\right)^{\psi/2} \right. \\ & \times \left. t^{3m} \left(\sqrt{6}c(\psi^2+2\psi-3)\sqrt{\frac{m^2}{t^2}} + 8\alpha(\psi-2)\psi\left(\frac{m^2}{t^2}\right)^{\psi/2} \right) - \xi \left(2\alpha\psi \right. \right. \\ & \times \left. \left. \left(\psi^2 - 6\psi + 8 \right) \left(\frac{m^2}{t^2} \right)^{\psi/2} - 3\sqrt{6}c(\psi-1)\sqrt{\frac{m^2}{t^2}} \right) \right) + 72\alpha m^3\psi t^{3m} \\ & \times \left. \left. \left(\frac{m^2}{t^2} \right)^{\psi/2} \left(\alpha(\psi+1)\left(\frac{m^2}{t^2}\right)^{\psi/2} - \sqrt{6}c(\psi-1)\sqrt{\frac{m^2}{t^2}} \right) \right) \right]. \end{aligned}$$

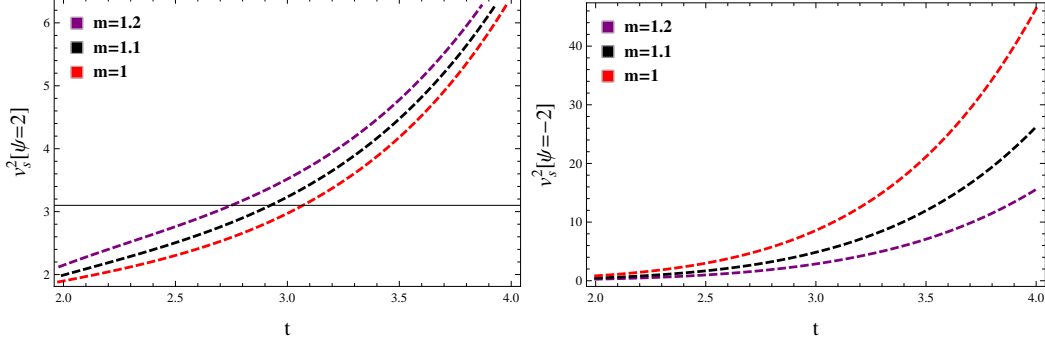

Figure 7: Graphs of ν_s^2 ($\psi = \pm 2$) with t .

Figure 7 indicates that ν_s^2 is positive and increases for various values of m and PDE parameters. This shows the stability of the reconstructed PDE $f(Q)$ model throughout cosmic evolution.

4 Reconstruction of GGPDE $f(Q)$ Model

Here, we reconstruct the GGPDE $f(Q)$ model through the corresponding principle. Using Eqs.(2) and (19), we obtain

$$\frac{f}{2} - 6H^2 f_Q = (\alpha H + \beta H^2)^\psi. \quad (24)$$

This implies the following solution

$$f(Q) = \frac{1}{6} \left(6c\sqrt{Q} - \alpha 6^{-\frac{\psi}{2}} Q^{\frac{\psi}{2}-1} \left(2\sqrt{6}\beta Q^{3/2} + \frac{12Q}{\psi-1} \right) \right). \quad (25)$$

This model with a power-law is found by substituting Eq.(9) into (25) as

$$f(Q) = \frac{\sqrt{6}c(\psi-1)\sqrt{\frac{m^2}{t^2}} - 2\alpha \left(\frac{m^2}{t^2}\right)^{\psi/2} \left(\beta(\psi-1)\sqrt{\frac{m^2}{t^2}} + 1\right)}{\psi-1}. \quad (26)$$

Figure 8 shows the behavior of the reconstructed GGPDE $f(Q)$ gravity model which decreases with increasing values of t for $\psi = 2$. On the other hand, for $\psi = -2$, $f(Q)$ increases with increasing values of t . The values of ρ_D and p_D are found using Eq.(25) in (19) and (20) as

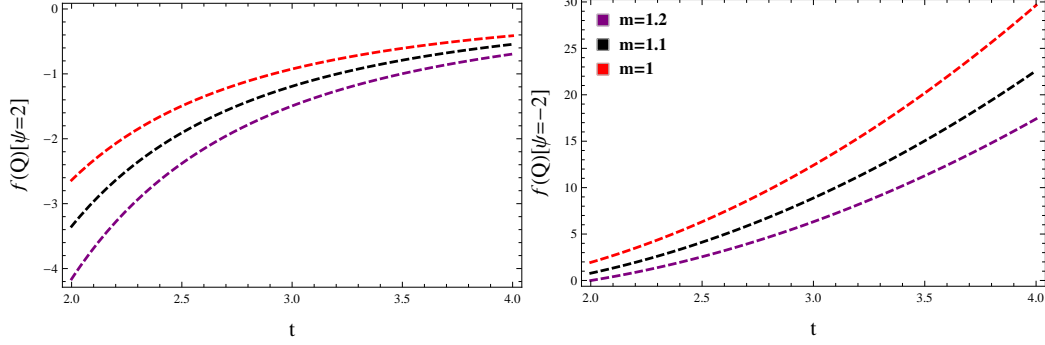

Figure 8: Graphical representation of $f(Q)$ ($\psi = \pm 2$) with t .

$$\begin{aligned} \rho_D &= \alpha 6^{-\frac{\psi}{2}-1} Q^{\psi/2} \left(\sqrt{6}\beta\sqrt{Q}\psi + 6 \right) + c, \\ p_D &= \frac{1}{Q^{5/2}(\psi-1)} \left[2^{\frac{1}{2}(-\psi-3)} 3^{-\frac{\psi}{2}-1} \left(cQ^2 2^{\frac{\psi+3}{2}} 3^{\frac{\psi}{2}+1} (\psi-1) \right. \right. \\ &\times (\dot{H} + 3H^2) - cHQ 2^{\frac{\psi+1}{2}} 3^{\frac{\psi}{2}+1} (\psi-1) + cQ^3 2^{\frac{\psi+1}{2}} 3^{\frac{\psi}{2}+1} \\ &\times (\psi-1) - 4\sqrt{3}\alpha\beta(\psi^2-1)(\dot{H} + 3H^2) Q^{\frac{\psi}{2}+2} - 12\sqrt{2} \\ &\times \alpha\psi(\dot{H} + 3H^2) Q^{\frac{\psi+3}{2}} - 2\sqrt{3}\alpha\beta H(\psi-1)^2(\psi+1) Q^{\frac{\psi}{2}+1} \\ &\left. \left. - 6\sqrt{2}\alpha(Q^{\frac{\psi+5}{2}} + H(\psi-2)\psi Q^{\frac{\psi+1}{2}}) - 2\sqrt{3}\alpha\beta(\psi-1) Q^{\frac{\psi}{2}+3} \right) \right]. \end{aligned}$$

Replacing Eq.(9) into the equations above, we can represent them in terms of t as

$$\begin{aligned} \rho_D &= \alpha \left(\frac{m^2}{t^2} \right)^{\psi/2} \left(\beta\psi\sqrt{\frac{m^2}{t^2}} + 1 \right), \\ p_D &= \frac{1}{72\sqrt{3}m^5(\psi-1)} \left[\sqrt{\frac{m^2}{t^2}} \left(m^2 t^2 \left(24\sqrt{3}\alpha\psi \left(\frac{m^2}{t^2} \right)^{\frac{\psi+1}{2}} - t \right. \right. \right. \\ &\times (\psi-1) \left(3\sqrt{2}c + 2\sqrt{3}\alpha\beta \left(\psi^2-1 \right) \left(\frac{m^2}{t^2} \right)^{\frac{\psi}{2}} \right) \left. \right) - 72m^5 \\ &\times (\psi-1) \left(\sqrt{3}\alpha\beta(\psi+2) \left(\frac{m^2}{t^2} \right)^{\frac{\psi}{2}} - 3\sqrt{2}c \right) + 12(\psi-1) \end{aligned}$$

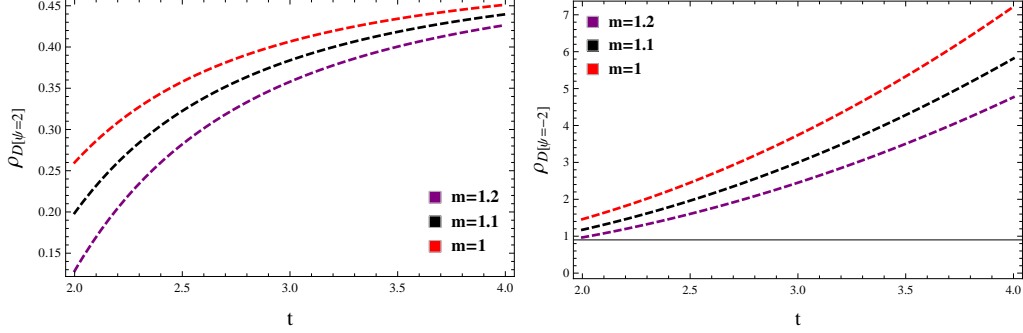

Figure 9: Plots of ρ_D ($\psi = \pm 2$) with t .

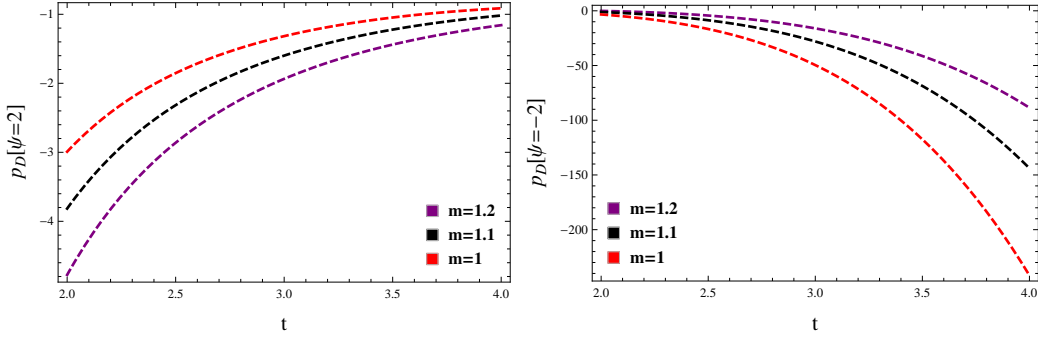

Figure 10: Plots of p_D ($\psi = \pm 2$) against t .

$$\begin{aligned}
 & \times m^4 \left(2\sqrt{3}\alpha\beta(\psi + 1) \left(\frac{m^2}{t^2} \right)^{\frac{\psi}{2}} - 3\sqrt{2}c \right) - 2\sqrt{3}\alpha t^5 (\psi - 2) \\
 & \times \left[\psi \left(\frac{m^2}{t^2} \right)^{\frac{\psi+1}{2}} - 72\sqrt{3}\alpha m^3 t^2 (\psi + 1) \left(\frac{m^2}{t^2} \right)^{\frac{\psi+1}{2}} \right].
 \end{aligned}$$

Figures **9** and **10** illustrate the behavior of p_D and ρ_D . In Figure **9**, the reconstructed GGPDE $f(Q)$ gravity shows an exponentially increasing behavior of ρ_D , for both $\psi = \pm 2$. On the other hand, in Figure **10**, for both $\psi = \pm 2$, p_D follows a negative trend that decreases over time, consistent with the expected DE behavior.

Now we examine the various phases of the universe evolution. We illustrate the behavior of different cosmological parameters, such as the EoS parameter and phase planes as well as stability of this model. The EoS pa-

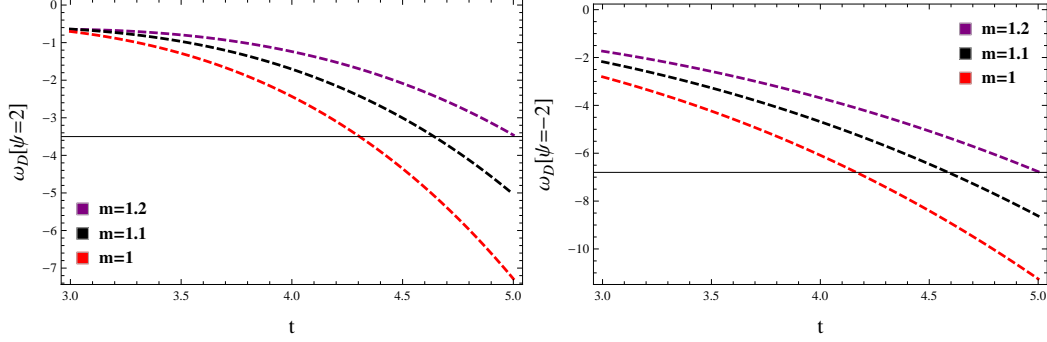

Figure 11: Graphs show of ω_D ($\psi = \pm 2$) versus t .

parameter is a crucial quantity in cosmology that describes the relationship between the pressure and the energy density of a given component of the universe. It plays a fundamental role in characterizing the nature of DE and its impact on the evolution of the universe. The EoS parameter is given by

$$\begin{aligned}
\omega_D = & - \left\{ \sqrt{\frac{m^2}{t^2}} t^{3m} \left(m^2 t^2 \left(t(\psi - 1) \left(3\sqrt{2}c + 2\sqrt{3}\alpha\beta \left(\psi^2 - 1 \right) \left(\frac{m^2}{t^2} \right)^{\psi/2} \right) \right. \right. \right. \\
& - 24\sqrt{3}\alpha\psi \left(\frac{m^2}{t^2} \right)^{\frac{\psi+1}{2}} \left. \left. \left. + 72m^5(\psi - 1) \left(\sqrt{3}\alpha\beta(\psi + 2) \left(\frac{m^2}{t^2} \right)^{\frac{\psi}{2}} - 3\sqrt{2}c \right) \right. \right. \right. \\
& - 12m^4(\psi - 1) \left(2\sqrt{3}\alpha\beta(\psi + 1) \left(\frac{m^2}{t^2} \right)^{\psi/2} - 3\sqrt{2}c \right) + 2\sqrt{3}\alpha t^5(\psi - 2)\psi \\
& \times \left(\frac{m^2}{t^2} \right)^{\frac{\psi+1}{2}} + 72\sqrt{3}\alpha m^3 t^2(\psi + 1) \left(\frac{m^2}{t^2} \right)^{\frac{\psi+1}{2}} \left. \left. \left. \right\} \left\{ 72\sqrt{3}m^5(\psi - 1) \right. \right. \\
& \times \left. \left. \left. \left(\alpha t^{3m} \left(\frac{m^2}{t^2} \right)^{\psi/2} \left(\beta\psi\sqrt{\frac{m^2}{t^2}} + 1 \right) + \xi \right) \right\}^{-1} .
\end{aligned}$$

Figure 11 shows that $\omega_D < -1$, implying that the model includes phantom field DE for both $\psi = \pm 2$, which aligns with the PDE phenomenon. The $\omega_D - \omega'_D$ -plane is used in cosmology to analyze the evolution and properties of DE. This plane can indicate whether a particular DE model evolves towards the different trajectories such as cosmological constant, phantom energy scenario or quintessence model. By examining these trajectories, one can conclude the important characteristics about the influence of DE on the universe expansion

and future evolution. The value of ω'_D is given as

$$\begin{aligned}
\omega'_D = & \left\{ t^{3m} \left(72m^5 t^{3m} \alpha \beta \psi \left(\psi^2 - 1 \right) \left(2\sqrt{3} \left(\frac{m^2}{t^2} \right)^{\psi/2} \alpha \beta - 3\sqrt{2}c \right) \left(\frac{m^2}{t^2} \right)^{\psi/2} \right. \right. \\
& - 12m^4 t^{3m} \alpha \beta (\psi - 1) \psi \left(4\sqrt{3} \left(\frac{m^2}{t^2} \right)^{\psi/2} \alpha \beta (\psi + 1) - 3\sqrt{2}(\psi + 2)c \right) \\
& \times \left(\frac{m^2}{t^2} \right)^{\psi/2} + 72m^3 t^2 \alpha \psi \left(t^{3m} \left(2\sqrt{3} \left(\frac{m^2}{t^2} \right)^{\psi/2} \alpha \left(2\sqrt{\frac{m^2}{t^2}} \beta \psi + 1 \right) \right. \right. \\
& - 3\sqrt{2} \sqrt{\frac{m^2}{t^2}} (\psi - 1)c \left. \left. - \sqrt{3} \xi (\psi - 1) \left(\sqrt{\frac{m^2}{t^2}} \beta (\psi + 1) + 1 \right) \right) \right) \left(\frac{m^2}{t^2} \right)^{\psi/2} \\
& + \left(t^{3m+1} \alpha \beta (\psi - 1) \psi \left(8\sqrt{3} \alpha \beta (\psi^2 - 1) \left(\frac{m^2}{t^2} \right)^{\psi/2} + 3\sqrt{2}(\psi + 4)c \right) \right. \\
& \times \left(\frac{m^2}{t^2} \right)^{\psi/2} + 12\xi \left(2\sqrt{3} \alpha \left(\sqrt{\frac{m^2}{t^2}} \beta (\psi + 1) (\psi - 1)^2 + (\psi - 2)\psi \right) \right. \\
& \times \left(\frac{m^2}{t^2} \right)^{\frac{\psi}{2}} + 3\sqrt{2}(\psi - 1)c \sqrt{\frac{m^2}{t^2}} \left. \left. + t^{3m} \left(36\sqrt{2} \left(\frac{m^2}{t^2} \right)^{\frac{\psi+1}{2}} \alpha (\psi^2 - 1)c \right. \right. \right. \\
& - 24\sqrt{3} \left(\frac{m^2}{t^2} \right)^{\psi} \alpha^2 \left(2\psi + \sqrt{\frac{m^2}{t^2}} \beta (4\psi^2 - 1) \right) \left. \left. \right) \right) m^2 t^2 + t^5 \left(t^{3m} \left(3\sqrt{2} \right. \right. \\
& \times \alpha (\psi^2 + 2\psi - 3)c \left(\frac{m^2}{t^2} \right)^{\frac{\psi+1}{2}} + 2\sqrt{3} \alpha^2 \left(4(\psi - 2)\psi + \sqrt{\frac{m^2}{t^2}} (3 + 8\psi^3 \right. \\
& - 13\psi^2 - 3\psi) \beta \left. \left. \right) \left(\frac{m^2}{t^2} \right)^{\psi} \right) - \xi \left(2\sqrt{3} \left(\frac{m^2}{t^2} \right)^{\frac{\psi}{2}} \alpha \left(\sqrt{\frac{m^2}{t^2}} \beta (\psi^2 - 2\psi - 3) \right. \right. \\
& \times (\psi - 1)^2 + \psi \left(\psi^2 - 6\psi + 8 \right) \left. \left. - 9\sqrt{2} \sqrt{\frac{m^2}{t^2}} (\psi - 1)c \right) \right) \left. \right\} \left\{ 864\sqrt{3} \right. \\
& \times \left. m^5 (\psi - 1) \left(t^{3m} \alpha \left(\sqrt{\frac{m^2}{t^2}} \beta \psi + 1 \right) \left(\frac{m^2}{t^2} \right)^{\psi/2} + \xi \right)^2 \right\}^{-1}.
\end{aligned}$$

Figure **12** demonstrates that $\omega_D < 0$, $\omega'_D < 0$ for all values of m and PDE parameter, indicating the existence of a freezing region. The $(r - s)$ -plane is a powerful tool in cosmology for differentiating between various DE models and understanding the cosmological dynamics. It uses a combination of the Hubble parameter and its time derivatives to analyze cosmic expansion. Specifically, the parameter s describes the acceleration of cosmic expansion,

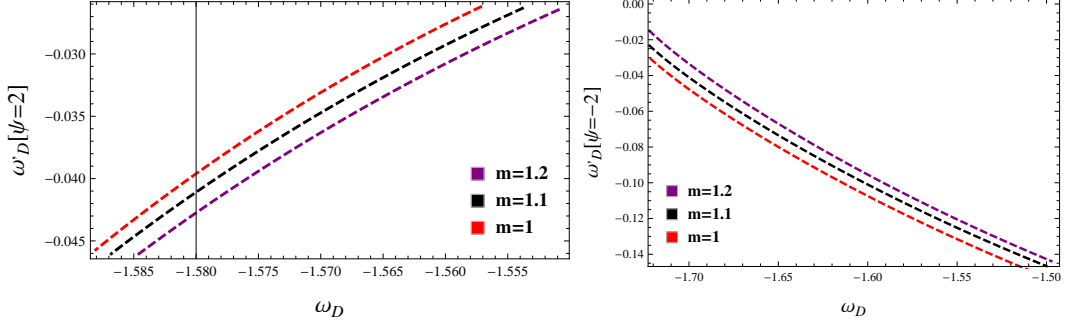

Figure 12: Plot of ω'_D ($\psi = \pm 2$) versus ω_D .

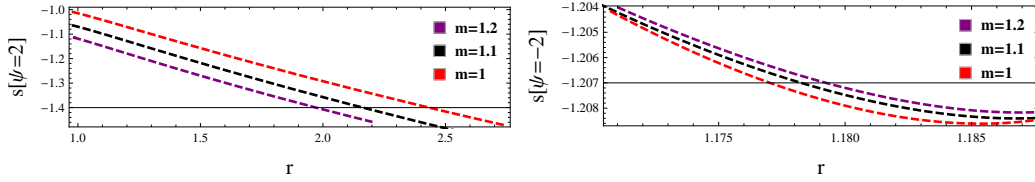

Figure 13: Plots illustrate s ($\psi = \pm 2$) with r .

while the parameter r shows deviations from pure power-law behavior. It can be used to distinguish between different DE scenarios like Chaplygin gas, Holographic DE, standard cold DM and quintessence without relying on any particular model. The values of r and s are given in Appendix B. Figure 13 shows the Chaplygin gas model ($r > 1$, $s < 0$) for various values of m and PDE parameter. In cosmology, especially in DE models, ν_s^2 helps to determine the stability of the universe expansion. A positive value indicates a stable configuration, while a negative value suggests unstable behavior for the corresponding model. Thus, the squared speed of sound is essential for understanding the dynamics of various components in the universe. The value of ν_s^2 turns out to be

$$\begin{aligned} \nu_s^2 &= - \left\{ \left(\frac{m^2}{t^2} \right)^{\frac{1}{2} - \frac{\psi}{2}} t^{3m} \left(2\sqrt{3}t^5 \alpha(\psi - 2)\psi \left(\frac{m^2}{t^2} \right)^{\frac{\psi+1}{2}} + 72\sqrt{3}m^3 t^2 \alpha(\psi + 1) \right. \right. \\ &\times \left. \left(\frac{m^2}{t^2} \right)^{\frac{\psi+1}{2}} - 12m^4(\psi - 1) \left(2\sqrt{3} \left(\frac{m^2}{t^2} \right)^{\psi/2} \alpha\beta(\psi + 1) - 3\sqrt{2}c \right) + 72 \right\} \end{aligned}$$

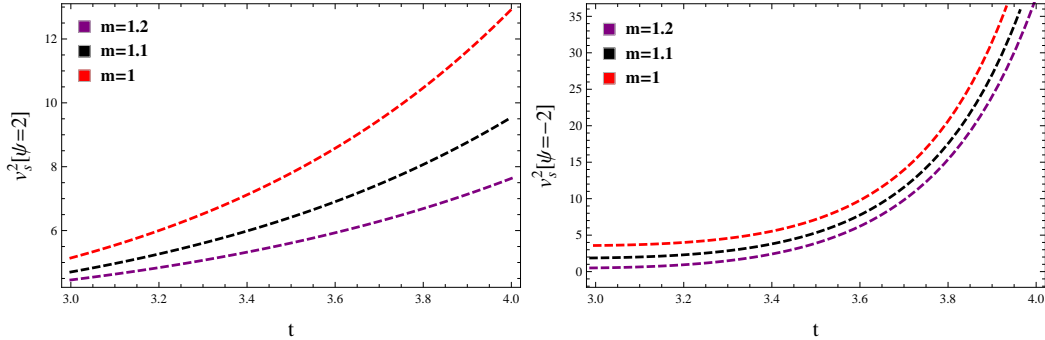

Figure 14: Graphs of ν_s^2 ($\psi = \pm 2$) versus t .

5 Conclusions

In this paper, we have explored two different DE models in the context of $f(Q)$ gravity. We have reconstructed PDE and GGPDE $f(Q)$ gravity models through a correspondence scheme for the FRW model with a power-law scale factor to examine the non-interacting case. We have then analyzed the evolutionary trajectories of the EoS as well as the $\omega_D - \omega'_D$ and the $(r - s)$ -planes. Finally, we have explored the stability of the DE model. The summary of the results obtained are presented as follows.

- Both DE models exhibit a decreasing pattern when $\psi = 2$, but an increasing trend when $\psi = -2$, suggesting that the reconstructed model is realistic (Figures 1 and 8).
- In both models, the energy density increases and pressure decreases for all values of ψ and m . This behavior aligns with the characteristics of DE (Figures 2, 9 and 3, 10). For PDE and GGPDE models, the increasing energy density and decreasing pressure indicate that DE becomes more dominant as the universe evolves. This is crucial for the accelerated expansion observed in the universe today. Their alignment with the fundamental properties of DE supports their viability as explanations for one of cosmology's most significant observations. We have plotted the energy density and pressure and their behavior is consistent with [38].
- We have found that the EoS parameter shows phantom region as the values of m decreases (Figures 4 and 11). Consequently, our findings

support the current accelerated expansion of the universe. Planck 2015 measurements have suggested alternative values for ω_D with a confidence level of 95% [35]

$$\begin{aligned}\omega_D &= -1.023_{-0.096}^{+0.091} && \text{(Planck TT+LowP+ext),} \\ \omega_D &= -1.006_{-0.091}^{+0.085} && \text{(Planck TT+LowP+lensing+ext),} \\ \omega_D &= -1.019_{-0.080}^{+0.075} && \text{(Planck TT, TE, EE+LowP+ext).}\end{aligned}$$

It is important to highlight that in non-interacting universe models, the effective EoS parameter is found to be consistent with observable constraints. Notably, when comparing to the GGPDE model, the EoS parameter in the PDE model proves to be more compatible with observational data.

- The $\omega_D - \omega'_D$ -plane illustrates the freezing region for all values of m and the PDE parameter (Figures 5 and 12). This shows that the universe appears to undergo a more rapid expansion.
- The $(r - s)$ -plane behaves like the Chaplygin gas model in the non-interacting case for different values of m and PDE parameters (Figures 6 and 13).
- The behavior of ν_s^2 remains positive for all values of m , indicating stability (Figures 7 and 14).

The cosmography of PDE and GGPDE within the $f(Q)$ framework surpasses other modified gravity theories. The cosmography of PDE and GGPDE in $f(Q)$ gravity provides a more accurate, stable and consistent framework for understanding DE [13]-[15]. Thus we can conclude that our results are more accurate in descriptions of the cosmic accelerated expansion.

Appendix A: Calculation of r and s in PDE

$$\begin{aligned}r &= \frac{1}{m^{12} \left(t^{3m} \alpha \left(\frac{m^2}{t^2} \right)^{\frac{\psi}{2}} + \xi \right)^4 (\psi - 1)^2} \left[2^{-2\psi-11} 3^{-2(\psi+3)} t^{12} \left(-6^{2\psi+3} t^{3m-7} \right. \right. \\ &\times \left. \left. m^4 \left(t^{3m} \alpha \left(\frac{m^2}{t^2} \right)^{\psi/2} + \xi \right) (\psi - 1) \left(-72 \left(-t^{3m} \alpha \xi \left((\psi^2 + 7\psi - 14) \psi \right. \right. \right. \right.\end{aligned}$$

$$\begin{aligned}
