

CT-AGRG: AUTOMATED ABNORMALITY-GUIDED REPORT GENERATION FROM 3D CHEST CT VOLUMES

Theo Di Piazza^{1,2}

¹CREATIS, INSA Lyon, University of Lyon 1, Villeurbanne, France

²Hospices Civils de Lyon, Lyon, France

The rapid increase of computed tomography (CT) have created a need for robust automated analysis techniques in clinical settings to assist radiologists managing their growing workload. Existing methods generate entire reports directly from 3D CT images, without explicitly focusing on observed abnormalities. This unguided approach can result in repetitive content or incomplete reports. We propose a new anomaly-guided report generation model, which first predicts abnormalities and then generates targeted descriptions for each. Evaluation on a public dataset demonstrates significant improvements in report quality and clinical relevance. We extend our work by conducting an ablation study to demonstrate its effectiveness.

1. INTRODUCTION

Three-dimensional Computed Tomography (3D CT) scans have emerged as indispensable tools in medical imaging [1]. Given the rapidly increasing number of scans to analyze [2, 3, 4], the time-consuming nature of the task [5] and the important demand for specialized radiological expertise in numerous healthcare systems [6, 7], computed-aided diagnosis and automating report generation have emerged as an active research area [8, 9, 10]. Whether dealing with 2D [11, 12] or 3D [13, 14] images, numerous deep learning methods have been introduced to support healthcare professionals in tasks such as anomaly classification [13, 15], detection [16, 17, 18], segmentation [19, 20, 21], and report generation [9, 10, 22, 23]. Indeed, the availability of public datasets for 2D radiology images [12, 11] has facilitated the development of such methods [22, 23, 24, 25, 26, 27]. Recently, CT2Rep [10] has been presented as the first 3D method for automated report generation, trained and evaluated on the public CT-RATE dataset [14] of CT examination. CT2Rep, uses an Encoder-Decoder model to generate reports directly from 3D CT scans. However, this end-to-end approach may lead to incomplete [6]. Reading a CT study and composing a report [28], a radiologist detects abnormalities and then provide descriptions for each identified abnormality. Inspired by the radiologists' workflow, we propose a method that first predicts anomalies and then generates a specific sentence for each anomaly. Our contributions are as follows:

- We introduce a new abnormality-based sentence generation model that enhances chest 3D CT scan report generation performance, achievable with limited computational resources (single GPU, 24-hour training time).
- We leverage a pre-trained language model with biomedical domain knowledge that we condition to generate a sentence for each abnormality.
- We evaluate the model on a public dataset and we enhance our findings with an ablation study to show the effectiveness of each module.

2. RELATED WORK

2.1. 2D Radiology report generation

Image captioning has emerged as a crucial task across diverse research domains [29, 30, 31, 32, 33]. This field has garnered significant attention in recent years in recent years [34, 35, 36], with applications in automated medical image reporting [37]. Early supervised methods for 2D radiology report generation [11, 12] primarily used Encoder-Decoder architectures [24, 25, 38]. The features of the input image are extracted using an encoder, either a CNN [39] or a Vision Transformer [40, 41]. These image-level features are then passed to a decoder, corresponding to a RNN [42] or Transformer Decoder [23, 26], which predicts the corresponding report. More recent methods introduce relational memory [23], pathology tags [43], or reinforcement learning [44] to improve the quality of generated reports. However, these methods generate the entire report only from the radiology image. Given the complexity and the inherent variability in radiological findings, these methods tend to produce incomplete reports [6]. Guided methods were then introduced to facilitate report generation [45, 46]. Descriptive sentences specific to identified regions or predicted abnormalities can be generated through the integration of an anatomical region detection or abnormality classification module [22].

2.2. 3D Radiology report generation

New challenges arise with 3D imaging [48, 49]. Compared to 2D images, this modality of data introduces new difficul-

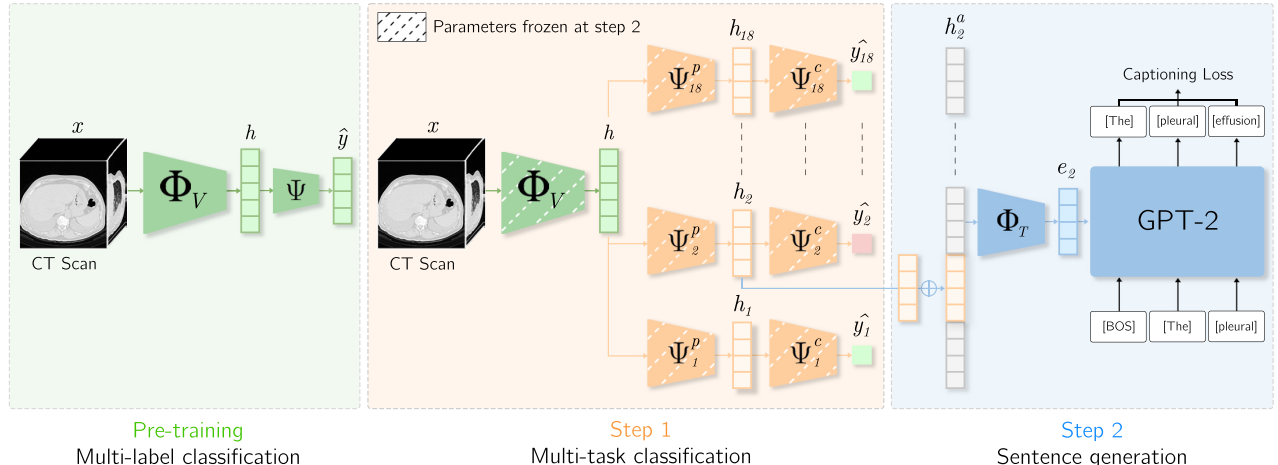

Fig. 1: Overview of the method. **Pre-training.** The input volume x is passed through a visual extractor Φ_V (either CT-ViT [47] or CT-Net [13]) to extract an embedding h . h is then given to classification head Ψ which predicts the logit vector \hat{y} . **Step 1.** h is fed into 18 projection heads ($\Psi_i^p, i \in \{1, \dots, 18\}$) followed by small classification heads ($\Psi_i^c, i \in \{1, \dots, 18\}$), one for each label. This second step enables to obtain an embedding h_i (and then h_i^a) specific to each label. **Step 2.** If a label indexed by i is predicted as abnormal by its corresponding classification head Ψ_i^c , the associated embedding h_i^a is transformed by a lightweight MLP $\Phi_T(e_i)$ to obtain e_i . An abnormality-specific description is generated from a pre-trained GPT-2 using e_i .

ties due to the limited availability of public datasets [10] in this field and the significant computational resources needed [48, 49]. Abnormality detection [18, 50] and classification [13, 14] for 3D CT scans have been the subject of research efforts in recent years. The Transformer-based visual feature extractor CT-ViT [47] has been introduced to deal with 3D CT scan efficiently, enabling the development of CT2Rep [10]. CT2Rep is the first method for automatic 3D CT scan radiology report generation, trained and evaluated on the CT-RATE public dataset [14]. CT2Rep is an auto-regressive model based on an encoder-decoder architecture [23], where visual features are extracted from the 3D CT scan using CT-ViT and then given to a Transformer Decoder [23, 41] that generates the report. To improve the completeness of generated reports, our approach builds upon previous work [22, 51] and introduces a step for abnormality classification to guide report generation based on previously predicted anomalies. This method offers greater control over the generation process.

3. DATASET

We use the CT-RATE public dataset [14] to train and evaluate our method. CT-RATE contains reconstructed non-contrast 3D chest CT volumes, corresponding reports and 18 distinct types of abnormalities extracted from reports using RadBERT [14, 52]. Train set has 17,799 unique patients (34,781 volumes), validation set has 1,314 patients (3,075 volumes) and test set has 1,314 patients (3,039 volumes). Following [13, 14], all volumes are either center-cropped or padded

to achieve a resolution of $240 \times 480 \times 480$ with a in-slice spacing of 0.75 mm and 1.5 mm in the z-axis. Hounsfield Unit (HU) [53] values are clipped between -1000 to $+200$ before normalization to $[-1, 1]$.

4. METHOD

As illustrated in Figure 1, we employ a two-stage approach for anomaly detection and description generation. Initially, we use a visual feature extractor pre-trained on a multi-label classification task. In the first stage, we perform multi-task learning with one classification head per anomaly. If an anomaly is detected, its associated vector representation is then passed to the second stage. Here, a pre-trained GPT-2 model generates a descriptive text of the identified anomaly.

4.1. Multi-label classification pre-training

The model receives a volume $x \in \mathbb{R}^{240 \times 480 \times 480}$ as input. This volume is passed to a visual feature extractor Φ_V , either CT-Net [13] or CT-ViT [47]. CT-Net consists of ResNet [54] modules pre-trained on ImageNet [55] followed by a 3D convolutional network [56]. CT-ViT [47] is a Vision Transformer [40] based on the attention mechanism [41] computed from 3D patches extracted from the initial volume. From the initial volume x , both CT-Net and CT-ViT yield a vector representation $h \in \mathbb{R}^{512}$, such that:

$$h = \Phi_V(x). \quad (1)$$

Then, h is fed into a classification head Ψ to predict $\hat{y} \in \mathbb{R}^{18}$, as follows:

$$\hat{y} = \Psi(h), \quad (2)$$

where the components of the logit vector \hat{y} represent the anomaly scores for their respective class labels. The model is trained using a binary cross-entropy loss function [57, 58]. This initial step facilitates the training of a visual encoder Φ_V to extract salient visual features that enable accurate anomaly prediction.

4.2. Step 1: Multi-task single label classification

The multi-label classification head Ψ of the pre-trained network is replaced by 18 independent projection heads [59], denoted as Ψ_i^p ($i \in \{1, \dots, 18\}$), followed by classification heads denoted as Ψ_i^c ($i \in \{1, \dots, 18\}$). The feature vector h is first passed through each projection head Ψ_i^p to obtain a unique embedding noted h_i per class label, such that:

$$h_i = \Psi_i^p(h) \quad \forall i \in \{1, \dots, 18\}. \quad (3)$$

Subsequently, each embedding h_i is fed into its corresponding classification head Ψ_i^c . The classification head outputs an anomaly score $\hat{y}_i \in \mathbb{R}$ and employs a binary cross-entropy loss $\mathcal{L}_i \in \mathbb{R}$ as the objective function. The prediction step can be formalized as:

$$\hat{y}_i = \Psi_i^c(h_i) \quad \forall i \in \{1, \dots, 18\}. \quad (4)$$

Here, \hat{y}_i represents the predicted anomaly score for class i . The binary cross-entropy loss is then computed for each class, such that:

$$\mathcal{L}_i(\hat{y}_i, y_i) = -[y_i \log(\hat{y}_i) + (1 - y_i) \log(1 - \hat{y}_i)], \quad (5)$$

where $y_i \in \{0, 1\}$ denotes the ground-truth label for class i .

For each projection Ψ_i^p and classification Ψ_i^c head, back-propagation [60] of the corresponding parameters is performed solely based on the associated loss \mathcal{L}_i . For the rest of the neural network, back-propagation is carried out using the sum of these losses, denoted as $\mathcal{L} \in \mathbb{R}$. Introducing this supervised multi-task learning step enhances classification performance [61] and enables the extraction of a unique vector representation h_i for each abnormality i , conditioning sentence generation per abnormality in the subsequent step.

4.3. Step 2: Abnormality-based sentence generation

Abnormality selection A description is generated for each abnormality predicted by the classification module. During the training of this generation module, we consider only the labels correctly predicted as abnormal by the classification heads. During inference, we only consider labels predicted as abnormal by the corresponding classification heads. A label i is classified as abnormal if its predicted score \hat{y}_i exceeds a

threshold computed from the validation set, which maximizes the F1-Score [62, 63, 64].

Abnormality feature extraction For each label indexed by i and predicted as abnormal by its corresponding classification head Ψ_i^c , we extract and expend the corresponding embedding $h_i \in \mathbb{R}^{1024}$ to obtain a vector $h_i^a \in \mathbb{R}^{18 \times 1024}$. This vector h_i^a contains zeros for all components associated with other abnormalities, while retaining the original embedding h_i . Using a lightweight MLP noted Φ_T , we project h_i^a from the visual latent space to the textual latent space, yielding $e_i \in \mathbb{R}^{1024}$, such that:

$$e_i = \Phi_T(h_i^a), \quad (6)$$

$$\text{where } h_i^a = [\vec{0}, \dots, \vec{0}, h_i, \vec{0}, \dots, \vec{0}],$$

and $\vec{0}$ denotes a zero vector of dimension 1024.

This allows for a focused representation of the predicted abnormality within the multi-abnormality embedding space, while maintaining the context of the original embedding.

Sentence generation For each label i predicted as abnormal, we generate a descriptive sentence based on its associated embedding e_i . Inspired by prior work [22], the GPT-2 Medium Language model [65] fine-tuned on PubMed abstracts [66] is used for the Decoder part. GPT-2 is an auto-regressive model grounded in attention mechanism [41] where each embedded token only considers the contextual information provided by preceding tokens. Instead of using the conventional attention mechanism, the language model is conditioned on anomaly prediction by employing pseudo self-attention [67], noted PS . This approach injects the features associated with abnormality classification into the self-attention mechanism of GPT-2, such that:

$$PS(e_i, Y) = \text{softmax} \left((YW_q) \left[\begin{array}{c} e_i w_k \\ Y W_k \end{array} \right]^T \right) \left[\begin{array}{c} e_i w_v \\ Y W_v \end{array} \right], \quad (7)$$

where w_k and w_v are the projection parameters for key and value vectors [41] for e_i ; W_k , W_q and W_v are the projection parameters for key, query and value for Y which are textual embedded tokens. During training, the model is trained on a next token prediction task [68] using a cross-entropy loss function [10, 22, 23]. All parameters are frozen except for those of GPT-2. During inference, only the CT scan and the [BOS] token [65] are fed into the model, which generates a description for each predicted abnormality.

Report generation The final report is obtained by concatenating the generated sentences associated with each predicted anomaly.

5. EXPERIMENTAL SETUP

Training details. For the first and second steps, the model was trained with a batch size of 4, using the Adam [69] optimizer for 40 and 2 epochs, with a learning rate of 10^{-4} and 10^{-5} , respectively. For the third step, training was conducted

Table 1: Quantitative evaluation on the test set with Natural Language Generation (NLG) metrics and Clinical Efficacy (CE) metrics. Our model outperforms the previous method both on NLG and CE metrics. *Ablation study:* The evaluation on NLG and CE metrics highlights the contribution of each module of our method. The ablation study on CT-AGRGR was conducted with CT-Net [13] as visual feature extractor, since it yields the best results.

for 50 epochs with a batch size of 64, using the AdamW [70] optimizer with a learning rate of 5×10^{-5} . The training required a GPU with 48GB of memory.

Generation mode. Generated sentences were limited to 60 tokens [71], typically the maximum observed per sentence in the report corpus. At inference, we use the Beam Search [72, 73, 74] algorithm as generation mode [75, 76, 77, 78]. Beam size is set to 4, aligning with prior work and balancing output quality with computational efficiency. [10, 22, 23].

6. RESULTS

6.1. Quantitative results

Abnormalities mentioned in the generated report are extracted with the RadBERT labeler [14, 52]. These predicted anomalies are compared against ground truth labels to compute Clinical Efficacy (CE) metrics: Precision, Recall, and F1-Score [79]. We also evaluate our captioning model using widely used [10, 22, 23, 26] Natural Language Generation (NLG) metrics: BLEU-1 and BLEU-4 [80] for n-gram precision; METEOR [81] for alignment with stemming and synonymy; ROUGE [82] for overlap focusing on recall; BERT-Score [83] for token-level contextual embedding similarity; and BART-Score [84] for sequence-level likelihood assessment. This combination captures lexical, semantic, and generative aspects of caption quality, providing a comprehensive evaluation of our model’s performance [85, 86]. Table 1 demonstrates that CT-AGRGR achieves significantly better results than prior work. With CT-ViT and CT-Net as visual feature extractors, we achieve an average Recall of 0.638 and 0.650 ($\Delta+74\%$ and $\Delta+77\%$ increase compared to CT2Rep [10]), and an average F1-Score of 0.426 and

0.515, respectively ($\Delta+18\%$ and $\Delta+43\%$ increase). CT-AGRGR achieves a BART-Score [84] of -2.900, outperforming CT2Rep [10] (-3.178, $\Delta+9\%$ increase), indicating enhanced abnormality detection capabilities and improved semantic relevance in generated captions.

6.2. Ablation study

As shown in Table 1, we conduct an ablation study to evaluate each component of our CT-AGRGR model. Introducing multi-task classification significantly improves F1-Score from 0.208 to 0.492 ($\Delta+136\%$ increase). Augmenting the latent space further enhances performance, increasing Recall from 0.617 to 0.650 ($\Delta+5\%$ increase) and F1-Score from 0.492 to 0.515 ($\Delta+5\%$ increase). NLG metrics show notable improvements, with BLEU-4 [80] and METEOR [81] scores increasing by 0.092 and 0.082, respectively, indicating enhanced sentence variability while maintaining semantic fidelity to ground truth reports.

7. CONCLUSION

In this paper, we have presented an effective method for guided report generation. Our approach, based on conditional description generation for each abnormality, outperforms state-of-the-art methods while offering a high level of control over the generated report. Future work could focus on adapting the approach to require less supervision, leveraging other modalities or region-specific data to further enhance the report generation process.

8. ACKNOWLEDGMENTS

We acknowledge Hamamci et al. 2024 [14] for making the CT-RATE dataset available.

Table 2: Quantitative evaluation on the test set with Precision (P), Recall (R) and F1-Score (F1) for each pathology. Frequency of each pathology in the test set is also provided. The metrics associated with CT-AGRG were computed using CT-Net [13] as the visual feature extractor, as this configuration yielded the best performance. The underlined metrics are those that have improved with our contribution compared to the previous method. Our method improves the classification metrics for the majority of abnormalities.

B. QUALITATIVE RESULTS

	<p>Ground truth</p> <p>A millimetric calcific atherosclerotic plaque was observed in the wall of the thoracic aorta. Sliding type hiatal hernia was observed. A few millimetric nonspecific parenchymal nodules were observed in both lungs. When examined in the lung parenchyma window; mosaic attenuation pattern was observed in both lungs.</p> <hr/> <p>Generation with CT2Rep</p> <p>There are atheromatous plaques in the aorta. There is a sliding type hiatal hernia at the lower end of the esophagus. There are millimetric nonspecific nodules in both lungs.</p> <hr/> <p>Generation with CT-GRG</p> <p>Atheroma plaques are observed in the aorta and coronary arteries. Sliding type hiatal hernia was observed at the lower end of the esophagus. There are millimetric nonspecific nodules in both lungs. When examined in the lung parenchyma window; mosaic attenuation pattern is observed in both lungs.</p>
	<p>Ground truth</p> <p>Diffuse atheroma plaques are observed in the aorta and coronary arteries. There are atelectasis in both lower lobes of the lungs adjacent to the pleural effusion. Bilateral pleural effusion is observed. There are minimal emphysematous changes in both lungs.</p> <hr/> <p>Generation with CT2Rep</p> <p>There are calcified atheromatous plaques on the walls of the thoracic aorta and coronary vascular structures. There is a sliding type hiatal hernia at the lower end.</p> <hr/> <p>Generation with CT-GRG</p> <p>Calcific atheroma plaques are observed in the aorta and coronary arteries. when examined in the lung parenchyma window atelectatic changes were observed in the lower lobes of both lungs. There is bilateral minimal pleural effusion. Heart size increased. There is minimal pericardial effusion.</p>
	<p>Ground truth</p> <p>Millimetric calcific atheroma plaques are observed in the anterior descending coronary artery and aorta. Sliding type hiatal hernia is observed at the esophagogastric junction. Atelectasis and local volume loss are observed in the left lung upper lobe lingular segment inferior subsegment, right lung middle lobe medial segment, left lung lower lobe medial segment. Minimal emphysematous changes are present in both lungs. Approximately 10 nodules are observed in both lungs, the largest of which is in the medial segment of the middle lobe, with a periphery location of 6x7.</p> <hr/> <p>Generation with CT2Rep</p> <p>Calcified atherosclerotic changes were observed in the wall of the thoracic aorta and coronary artery. Sliding type hiatal hernia was observed. Heart size increased. When examined in the lung parenchyma window mosaic attenuation pattern was observed in both lungs small airway disease small vessel disease</p> <hr/> <p>Generation with CT-GRG</p> <p>Calcified atherosclerotic changes were observed in the wall of the thoracic aorta and coronary artery. Sliding type hiatal hernia was observed at the lower end of the esophagus. When examined in the lung parenchyma window linear atelectasis was observed in the lower lobes of both lungs. There are emphysematous changes in both lungs. There are millimetric nonspecific nodules in both lungs. There are millimetric lymph nodes in the mediastinum. When examined in the lung parenchyma window pleuroparenchymal sequelae density increases were observed in both lungs.</p>
	<p>Ground truth</p> <p>Subsegmental atelectatic changes were observed in the medial segment of the right lung middle lobe. Centriacinar nodular infiltrates tend to coalesce with each other and occasionally to form focal consolidation. When examined in the lung parenchyma window; There are diffuse ground glass areas in both lungs, miliary and centriacinar nodular infiltrates at this level. There are bilateral axillary upper lower paratracheal, anterior prevascular, aortopulmonary, subcarinal, bilateral hilar, paraesophageal multiple lymph nodes, the largest of which is 22.</p> <hr/> <p>Generation with CT2Rep</p> <p>In the evaluation of both lung parenchyma diffuse ground glass densities and consolidations are observed in both lung parenchyma. Right upper bilateral lower paratracheal millimetric lymph node is observed. In the evaluation of both lung parenchyma mosaic attenuation is observed in both lung parenchyma. The cardiothoracic index increased in favor of the heart.</p> <hr/> <p>Generation with CT-GRG</p> <p>When examined in the lung parenchyma window subsegmental atelectatic changes were observed in the lower lobes of both lungs. When examined in the lung parenchyma window in both lungs there are areas of consolidation in which air bronchograms are observed. When examined in the lung parenchyma window widespread patchy ground glass densities are observed in both lungs. There are lymph nodes in the mediastinum and hilar regions. There is minimal pericardial effusion. When examined in the lung parenchyma window peribronchial thickenings were observed in both lungs.</p>

Fig. 2: Comparison of ground truth with generated reports with CT2Rep [10] and CT-AGRG on test set from CT-RATE [14].

C. TRAINING STEPS

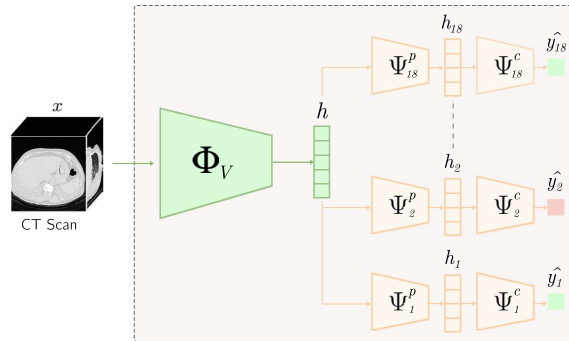

Pre-training: Multi-label classification pre-training

Φ_V, Ψ are trained from scratch.

Step 1: Multi-task single label classification

Φ_V is fine-tuned from weights extracted from Step 1.
 Ψ_i^p, Ψ_i^c are trained from scratch.

Step 2: Report generation

$\Phi_V, \Psi_i^p, \Psi_i^c$ parameters are frozen.

Φ_T is trained from scratch.

GPT-2 is fine-tuned from pre-trained weights on PubMed abstracts.

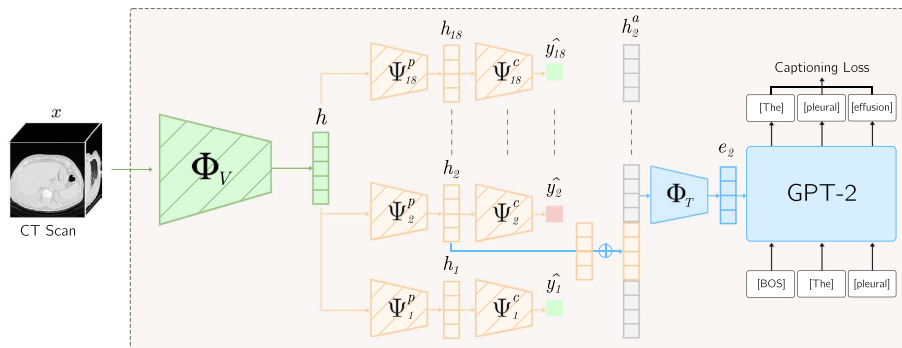

Fig. 3: Overview of the method with details for each step.

D. HYPERPARAMETERS

	Step 1	Step 1	Step 2	Step 2
	w/ CT-Net [13]	w/ CT-ViT [47]	w/ CT-Net [13]	w/ CT-ViT [47]
Optimizer	Adam [69]	Adam [69]	Adam [69]	Adam [69]
Learning rate - Visual Extractor	0.0001	0.0001	0.00001	0.00001
Learning rate - Classification Head(s)	0.0001	0.0001	0.00001	0.00001
Batch size	4	4	4	4
Epochs	50	50	2	2
Early stopping	✓	✓	✓	✓

Table 3: Hyperparameters of the training for each model on the classification steps 1 and 2. For each configuration, we use the hyper-parameters that yield the best results. Early stopping is performed to obtain the checkpoint with the highest F1-Score on the validation set.

	CT2Rep [10]	CT-AGRG
Optimizer	AdamW [70]	AdamW [70]
Learning rate - Visual Extractor	0.00005	-
Learning rate - Encoder Decoder	0.00005	0.00005
Weight decay	0.01	0.01
Batch size	16	64
Epochs	100	100
Early stopping	✓	✓
Tokenizer - Max. sequence length	400 / report	60 / sentence
Generation mode	Beam search	Beam search
Beam size	4	4

Table 4: Hyperparameters of the training for each model on the generation step. For each configuration, we use the hyper-parameters that yield the best results. Early stopping is performed to obtain the checkpoint with the highest F1-Score on the validation set, triggered only after a minimum of 10 epochs to ensure sufficient training time and comparable iterations across experiments.
