(Dated: August 23, 2024)

A tight-binding model for e_g orbitals on a simple cubic lattice with finite thickness is investigated. The hopping integrals for nearest-neighboring sites are considered. We examine the electronic band structures for systems with (001), (110), and (111) surfaces. Electronic states well localized around the surfaces are found for the (110) and (111) surfaces. In particular, the surface state is flat and extends in the entire Brillouin zone for the (111) surface, provided the bulk band projected onto the surface Brillouin zone is gapped. We also find that these surface states possess octupole moments in both the (110) and (111) surface cases.

I. INTRODUCTION

Topological semimetals are distinguished by the topological protection of band degeneracies, which can occur at discrete points, known as Dirac or Weyl points [1–4], or along continuous lines, referred to as topological nodal lines [5–7]. These materials have attracted considerable attention due to their unique and fascinating physical properties.

Achieving such topological features requires at least two electronic bands. In systems with two atomic sites per unit cell, such as honeycomb and diamond lattices, this condition is naturally met, leading to the presence of Dirac points [1, 2] and nodal lines [8], respectively. Another approach involves leveraging the spin degrees of freedom. For example, Rashba spin-orbit coupling [9] can lift the spin degeneracy of a band, except at specific kpoints where time-reversal symmetry ensures degeneracy, resulting in Weyl points [10].

Another possibility is to use the orbital degrees of freedom. We examine the e_g orbitals of d electrons as a prototypical example of two-orbital systems. Indeed, Dirac points have been investigated in two-dimensional e_g orbital systems [11–14]. In particular, in our previous study [14], we found edge states in an e_g orbital model on a square lattice, similar to the single-orbital honeycomb lattice model [15]. The edge state in the e_g orbital model possesses an octupole moment.

Here, we extend the e_g orbital model to a threedimensional system, specifically on a simple cubic lattice. We find topological nodal lines in this model. In the presence of such topological nodal lines, surface states are expected [5–7]. For example, in a single-orbital tightbinding model on a diamond lattice, a flat surface state appears on the (111) surface [16, 17]. In our model, we find flat surface states in the entire Brillouin zone for the (111) surface as long as the bulk band projected onto the surface Brillouin zone is gapped. This contrasts with the single-orbital model on a diamond lattice, where the flat surface state appears only in a part of the surface Brillouin zone. Additionally, the surface state in our model possesses an octupole moment.

II. MODEL

In this paper, we omit considerations of a magnetic field and magnetic ordering. Consequently, we can disregard the spin degrees of freedom and reduce our model to a spinless one. The Hamiltonian for a simple cubic lattice with nearest-neighbor hopping is given by

$$H = \sum_{\tau\tau'} c^{\dagger}_{\boldsymbol{k}\tau} \epsilon_{\tau\tau'}(\boldsymbol{k}) c_{\boldsymbol{k}\tau'}, \qquad (1)$$

where $c_{k\tau}$ is the annihilation operator for an electron with momentum k and orbital τ . Here, $\tau = 1$ corresponds to the $x^2 - y^2$ orbital and $\tau = 2$ corresponds to the $3z^2 - r^2$ orbital. The matrix elements of the Hamiltonian are given by [18, 19]

$$\epsilon_{11}(\mathbf{k}) = \frac{1}{2} [3(dd\sigma) + (dd\delta)](c_x + c_y) + 2(dd\delta)c_z, \quad (2)$$

$$\epsilon_{22}(\boldsymbol{k}) = \frac{1}{2} [(dd\sigma) + 3(dd\delta)](c_x + c_y) + 2(dd\sigma)c_z, \quad (3)$$

$$\epsilon_{12}(\boldsymbol{k}) = \epsilon_{21}(\boldsymbol{k}) = -\frac{\sqrt{3}}{2} [(dd\sigma) - (dd\delta)](c_x - c_y), \quad (4)$$

where $c_{\mu} = \cos k_{\mu} a$ with $\mu = x, y$, or z, and a is the lattice constant. $(dd\sigma)$ and $(dd\delta)$ represent the two-center integrals [20]. This model can be adapted to Γ_8 orbitals of felectrons by substituting $(dd\sigma)$ with $[3(ff\sigma)+4(ff\pi)]/7$ and $(dd\delta)$ with $[(ff\pi)+5(ff\delta)+15(ff\phi)]/21$. Since the model is for two orbitals, the matrix $\epsilon(\mathbf{k})$ can be expressed using the Pauli matrices:

$$\epsilon(\mathbf{k}) = \frac{1}{2} [\epsilon_{11}(\mathbf{k}) + \epsilon_{22}(\mathbf{k})] \sigma^{0} + \frac{1}{2} [\epsilon_{11}(\mathbf{k}) - \epsilon_{22}(\mathbf{k})] \sigma^{z} + \epsilon_{12}(\mathbf{k}) \sigma^{x}$$
(5)
$$= h_{0}(\mathbf{k}) \sigma^{0} + h_{x}(\mathbf{k}) \sigma^{x} + h_{z}(\mathbf{k}) \sigma^{z},$$

where σ^{μ} denotes the μ component of the Pauli matrix, and σ^{0} is the identity matrix. The coefficients are given by:

$$h_0(\mathbf{k}) = [\epsilon_{11}(\mathbf{k}) + \epsilon_{22}(\mathbf{k})]/2$$

= $[(dd\sigma) + (dd\delta)](c_x + c_y + c_z)$ (6)
= $2t_1(c_x + c_y + c_z),$

$$h_x(\mathbf{k}) = \epsilon_{12}(\mathbf{k}) = \epsilon_{21}(\mathbf{k})$$
$$= -\frac{\sqrt{3}}{2} [(dd\sigma) - (dd\delta)](c_x - c_y)$$
(7)

$$= -\sqrt{3}t_{2}(c_{x} - c_{y}),$$

$$h_{z}(\boldsymbol{k}) = [\epsilon_{11}(\boldsymbol{k}) - \epsilon_{22}(\boldsymbol{k})]/2$$

$$= \frac{1}{2}[(dd\sigma) - (dd\delta)](c_{x} + c_{y} - 2c_{z}) \qquad (8)$$

$$= t_{2}(c_{x} + c_{y} - 2c_{z}).$$

We define the parameters:

$$t_1 = [(dd\sigma) + (dd\delta)]/2, \tag{9}$$

$$t_2 = [(dd\sigma) - (dd\delta)]/2, \tag{10}$$

and assume $t_1 \ge 0$ and $t_2 \ge 0$ without loss of generality. Thus, we parametrize them as

$$t_1 = t \cos \alpha, \tag{11}$$

$$t_2 = t \sin \alpha, \tag{12}$$

with t > 0 and $0 \le \alpha \le \pi/2$.

This model has been studied across various contexts with different values of α . For $\alpha = 0$ $[t_2 = 0, (dd\delta) =$ $(dd\sigma)$, see Fig. 1(a)], the potential for anisotropic superconducting pairing arising from the orbital anisotropy of e_q orbitals has been explored [21]. Such anisotropic superconductivity has been investigated in the f-electron system $\Pr T_2 X_{20}$ (where T is a transition metal and X is Zn or Al) [22–25]. For $\alpha = \pi/4$ [$t_1 = t_2$, $(dd\delta) = 0$], the model has been applied to perovskite manganites [26] and to the Γ_8 orbitals of f electrons, considering only $(ff\sigma)$ [22–25, 27–34]. An effective Hamiltonian in the strong coupling limit is derived from this model, and frustration arising from the orbital anisotropy is discussed [35–39]. A similar frustrated model is known as the Kitaev model, which has been the subject of extensive study [40, 41]. In the two-dimensional version of the model for $\alpha = \pi/2$ $[t_1 = 0, (dd\delta) = -(dd\sigma)$, see Fig. 1(d)] near half filling, pocket Fermi surfaces appear around $(\pm \pi/2, \pm \pi/2)$. If a superconducting pair consists of electrons on the same Fermi pocket, the superconducting pair will possess a finite total momentum (π, π) , akin to the Fulde-Ferrell-Larkin-Ovchinnikov state [42, 43], even in the absence of a magnetic field, resembling the η -pairing state [44]. This possibility has been examined in Refs. [18, 19].

The energy dispersion of the model is given by

$$E(\mathbf{k}) = h_0(\mathbf{k}) \pm \sqrt{h_x^2(\mathbf{k}) + h_z^2(\mathbf{k})}$$

= $h_0(\mathbf{k}) \pm h(\mathbf{k}).$ (13)

Note that hybridization between the $x^2 - y^2$ and $3z^2 - r^2$ orbitals is prohibited on the $k_x = k_y$ plane due to

FIG. 1. Energy dispersion along symmetric directions for (a) $\alpha = 0$, (b) $\alpha = 0.2\pi$, (c) $\alpha = 0.4\pi$, and (d) $\alpha = 0.5\pi$. The high-symmetry points are $\Gamma = (0, 0, 0), X = (\pi/a, 0, 0), M = (\pi/a, \pi/a, 0)$, and $R = (\pi/a, \pi/a, \pi/a)$.

mirror symmetry [11, 12]. Additionally, these orbitals are degenerate along the $k_x = k_y = k_z$ line. Consequently, the two bands intersect along this and equivalent lines, $(k_x, k_y, k_z) \parallel (\pm 1, \pm 1, \pm 1)$. These lines are topological nodal lines.

In Fig. 1, we show the energy dispersion for some values of α . The two bands are degenerate along the nodal line (Γ -R line). The bandwidth W varies non-monotonically with α : W = 12t at $\alpha = 0$ [Fig. 1(a)], $W = 6\sqrt{2}t$ at $\alpha = 0.25\pi$, $W = 4\sqrt{5}t$ at $\alpha = \tan^{-1} 2 = 0.3524\pi$, and W = 8t at $\alpha = 0.5\pi$ [Fig. 1(d)].

We can define the winding number w of the normalized two-component vector field $\hat{\boldsymbol{h}}(\boldsymbol{k}) = \boldsymbol{h}(\boldsymbol{k})/h(\boldsymbol{k}) = [h_x(\boldsymbol{k}), h_z(\boldsymbol{k})]/h(\boldsymbol{k}) = [\hat{h}_x(\boldsymbol{k}), \hat{h}_z(\boldsymbol{k})]$ as follows,

$$w = \oint_C \frac{d\mathbf{k}}{2\pi} \cdot \left[\hat{h}_x(\mathbf{k}) \nabla \hat{h}_z(\mathbf{k}) - \hat{h}_z(\mathbf{k}) \nabla \hat{h}_x(\mathbf{k}) \right], \quad (14)$$

where C is a closed loop. For a loop encircling the nodal line $(0, 0, 0)-(a_x\pi/a, a_y\pi/a, a_z\pi/a)$ with $a_x, a_y, a_z = \pm 1$, we obtain $w = -a_x a_y a_z$.

In a model with finite thickness, i.e., with two parallel surfaces, we define the momentum \mathbf{k}_{\parallel} parallel to the surfaces. When \mathbf{k}_{\parallel} is fixed at a certain value, the system can be regarded as a one-dimensional system along the direction perpendicular to the surfaces. We denote the lattice constant of this one-dimensional model as \tilde{a} . The momentum k_{\perp} of this one-dimensional system is defined in the limit of infinite thickness. The winding number $w(\mathbf{k}_{\parallel})$ for the one-dimensional system is then given by

$$w(\mathbf{k}_{\parallel}) = \int_{0}^{2\pi/\tilde{a}} \frac{dk_{\perp}}{2\pi} \left[\hat{h}_{x}(\mathbf{k}) \frac{\partial}{\partial k_{\perp}} \hat{h}_{z}(\mathbf{k}) - \hat{h}_{z}(\mathbf{k}) \frac{\partial}{\partial k_{\perp}} \hat{h}_{x}(\mathbf{k}) \right]$$
(15)

The multipole operators at site $(i, \boldsymbol{r}_{\parallel})$ are defined as

$$\hat{\sigma}^{\mu}(i, \boldsymbol{r}_{\parallel}) = \sum_{\tau\tau'} c^{\dagger}_{i\boldsymbol{r}_{\parallel}\tau} \sigma^{\mu}_{\tau\tau'} c_{i\boldsymbol{r}_{\parallel}\tau'}, \qquad (16)$$

FIG. 2. Energy dispersion for a system with (001) surfaces along symmetric directions for (a) $\alpha = 0$, (b) $\alpha = 0.2\pi$, (c) $\alpha = 0.4\pi$, and (d) $\alpha = 0.5\pi$. The high-symmetry points are $\Gamma = (0,0), X = (\pi/a,0)$, and $M = (\pi/a,\pi/a)$. The number of layers perpendicular to the surfaces is $L_z = 31$.

where \mathbf{r}_{\parallel} is the position vector parallel to the surfaces, *i* denotes the position perpendicular to the surfaces, $c_{i\mathbf{r}_{\parallel}\tau}$ is the annihilation operator of the electron at site $(i, \mathbf{r}_{\parallel})$ with orbital τ , and $\mu = 0, x, y$, or *z*. The multipole operator at position *i* is given by

$$\hat{\sigma}^{\mu}(i) = \sum_{\boldsymbol{r}_{\parallel}} \hat{\sigma}^{\mu}(i, \boldsymbol{r}_{\parallel})
= \sum_{\boldsymbol{k}_{\parallel}\tau\tau'} c^{\dagger}_{i\boldsymbol{k}_{\parallel}\tau} \sigma^{\mu}_{\tau\tau'} c_{i\boldsymbol{k}_{\parallel}\tau'}
= \sum_{\boldsymbol{k}_{\parallel}} \hat{\sigma}^{\mu}(i, \boldsymbol{k}_{\parallel}),$$
(17)

where $c_{i\boldsymbol{k}_{\parallel}\tau}$ is the Fourier transform of $c_{i\boldsymbol{r}_{\parallel}\tau}$ parallel to the surfaces. The zeroth component is the charge operator $\hat{Q}(i) = \hat{\sigma}^{0}(i)$, the z and x components are the quadrupole operators $\hat{O}_{20}(i) = \hat{\sigma}^{z}(i)$ and $\hat{O}_{22}(i) = \hat{\sigma}^{x}(i)$, respectively, and the y component is the octupole operator $\hat{T}_{xyz}(i) = \hat{\sigma}^{y}(i)$ [45, 46].

III. (001) SURFACE

For the (001) surface case, $\mathbf{k}_{\parallel} = (k_x, k_y)$ and $k_{\perp} = k_z$. The lattice constant in the direction perpendicular to the surfaces is $\tilde{a} = a$. We find $w(\mathbf{k}_{\parallel}) = 0$ in the entire surface Brillouin zone.

In Fig. 2, we show the energy dispersion for a lattice with a finite thickness of $\tilde{a}L_z$, where $L_z = 31$. As expected from $w(\mathbf{k}_{\parallel}) = 0$, we observe no surface states isolated from the bulk states.

FIG. 3. Winding number $w(\mathbf{k}_{\parallel})$ in the first Brillouin zone for a system with (110) surfaces. The winding number $w(\mathbf{k}_{\parallel})$ is zero in the non-shaded areas.

IV. (110) SURFACE

For the (110) surface case, the lattice constant in the direction perpendicular to the surfaces is $\tilde{a} = a/\sqrt{2}$. We define $\mathbf{k}_{\parallel} = (k'_y, k_z)$ and $k_{\perp} = k'_x$, where k'_y is the momentum parallel to the surfaces and perpendicular to the z axis, and k'_x is the momentum perpendicular to the surfaces. The vector $\mathbf{h}(\mathbf{k})$ is expressed by using these momenta: $h_x(\mathbf{k}) = -2\sqrt{3}t_2\sin(k'_xa/\sqrt{2})\sin(k'_ya/\sqrt{2})$ and $h_z(\mathbf{k}) = 2t_2[\cos(k'_xa/\sqrt{2})\cos(k'_ya/\sqrt{2}) - c_z]$.

In Fig. 3, we show the winding number $w(\mathbf{k}_{\parallel})$ in the surface Brillouin zone. In the region where $w(\mathbf{k}_{\parallel}) \neq 0$, we expect a surface state, provided that the bulk band projected onto the surface Brillouin zone is gapped.

In Fig. 4, we show the energy band for a lattice with a finite thickness $\tilde{a}L_{x'}$ with $L_{x'} = 31$. For $\alpha = 0$, all the bands are degenerate for $k'_y = \pi/\sqrt{2}a$. For $\alpha < \tan^{-1} 2 = 0.3524\pi$, the bulk band gap is closed in the region where $w(\mathbf{k}_{\parallel}) \neq 0$. For $\alpha > \tan^{-1} 2$, the bulk band gap opens except on the lines where $w(\mathbf{k}_{\parallel})$ changes. For $\alpha > \tan^{-1} 2$, we observe surface states isolated from the bulk band in parts of S- Γ and X-Y lines, as shown in Figs. 4(c) and 4(d). The appearance of the surface states is in accord with the $w(\mathbf{k}_{\parallel}) \neq 0$ region in Fig. 3.

For a fixed k_z , the model is reduced to a twodimensional model with the difference in the energy levels of orbitals $\Delta = -4t_2c_z$ and an energy shift of $2t_1c_z$. Using the results of the two-dimensional model [14], we obtain the energy of the surface state: $E = -\Delta/\tan \alpha + 2t_1c_z = 6t_1c_z$. The energy dispersions of the surface state on the S- Γ and X-Y lines for $\alpha = 0.4\pi$ in Fig. 4(c) and for $\alpha = 0.5\pi$ in Fig. 4(d) are given by this equation.

From the results of the two-dimensional model, we also conclude that, at $(k'_y, k_z) = [\pi/(3\sqrt{2}a), \pi/(2a)]$, the surface state is completely localized on the first layer of the surface with a fully polarized octupole moment for

FIG. 4. Energy dispersion for a system with (110) surfaces along symmetric directions at (a) $\alpha = 0$, (b) $\alpha = 0.2\pi$, (c) $\alpha = 0.4\pi$, and (d) $\alpha = 0.5\pi$. The high-symmetry points are $\Gamma = (0,0)$, $X = (\pi/\sqrt{2}a, 0)$, $Y = (0, \pi/a)$, and $S = (\pi/\sqrt{2}a, \pi/a)$. The number of layers perpendicular to the surfaces is $L_{x'} = 31$. The solid circles in (c) and (d) indicate the surface states in which the multipole density is evaluated in Figs. 5(a) and 5(b), respectively.

FIG. 5. Multipole density in the surface state for a lattice with (110) surfaces at $\mathbf{k}_{\parallel} = 0.4 \times S$ (a) for $\alpha = 0.4\pi$ [see Fig. 4(c)] and (b) for $\alpha = 0.5\pi$ [see Fig. 4(d)]. The number of layers perpendicular to the surfaces is $L_{x'} = 31$, and $S = (\pi/\sqrt{2a}, \pi/a)$.

 $\alpha = 0.5\pi$. For other \mathbf{k}_{\parallel} and α , we need to evaluate the multipole density numerically.

We show the multipole density around the surfaces for $\alpha = 0.4\pi$ in Fig. 5(a) and for $\alpha = 0.5\pi$ in Fig. 5(b) at $\mathbf{k}_{\parallel} = 0.4 \times S$ with $S = (\pi/\sqrt{2}a, \pi/a)$. The surface

FIG. 6. Octupole density on the top layer $i = (L_{x'} - 1)/2$ of the (110) surface in the surface state (a) for $\alpha = 0.4\pi$ and (b) for $\alpha = 0.5\pi$. The number of layers perpendicular to the surfaces is $L_{x'} = 101$.

states are doubly degenerate, and we show the total multipole density of these two states. From the charge density $Q(i) = \langle \hat{Q}(i) \rangle$, where $\langle \cdots \rangle$ denotes the sum of the expectation values in the two surface states, we recognize that these states are localized around the surfaces. $O_{22}(i) = \langle \hat{Q}_{22}(i) \rangle$ is always zero, and $O_{20}(i) = \langle \hat{Q}_{20}(i) \rangle$ is also zero for $\alpha = 0.5\pi$. The octupole moment $T_{xyz}(i) = \langle \hat{T}_{xyz}(i) \rangle$ is opposite between the surfaces.

In Fig. 6, we show the octupole density on the top layer $i = (L_{x'} - 1)/2$ in the surface state. As we noted, at $(k'_y, k_z) = [\pi/(3\sqrt{2}a), \pi/(2a)]$ (at the center of mass of the triangle) for $\alpha = 0.5\pi$, the octupole density reaches unity.

V. (111) SURFACE

For the (111) surface case, the lattice constant in the direction perpendicular to the surfaces is $\tilde{a} = a/\sqrt{3}$. We define $\mathbf{k}_{\parallel} = (k'_x, k'_y)$ and $k_{\perp} = k'_z$. The top layer of the (111) surface forms a triangular lattice. Here, k'_x is the momentum parallel to one of the edges of a triangle in the triangular lattice, k'_y is the momentum parallel to the surfaces and perpendicular to the k'_x axis, and k'_z is the momentum perpendicular to the surfaces. The vector $\mathbf{h}(\mathbf{k})$ is expressed using these momenta as follows: $h_x(\mathbf{k}) = 2\sqrt{3}t_2 \sin(k'_x a/\sqrt{2}) \sin(k'_y a/\sqrt{6} - k'_z a/\sqrt{3})$ and $h_z(\mathbf{k}) = 2t_2[\cos(k'_x a/\sqrt{2})\cos(k'_y a/\sqrt{6} - k'_z a/\sqrt{3}) - \cos(2k'_y a/\sqrt{6} + k'_z a/\sqrt{3})].$

In Fig. 7, we show the winding number $w(\mathbf{k}_{\parallel})$ in the reciprocal space parallel to the surfaces. The winding number is nonzero except along the $\Gamma-M$ [(0,0)– $(0,\sqrt{2\pi}/\sqrt{3}a)$] and equivalent lines. Thus, we expect a surface state at any \mathbf{k}_{\parallel} as long as the bulk band projected onto the surface Brillouin zone is gapped there.

In Fig. 8, we show the energy band for a lattice with a finite thickness $\tilde{a}L_{z'}$ with $L_{z'} = 31$. The size effect

FIG. 7. Winding number $w(\mathbf{k}_{\parallel})$ for a system with (111) surfaces. The area enclosed by the solid line is the first Brillouin zone.

FIG. 8. Energy dispersion for a system with (111) surfaces along symmetric directions at (a) $\alpha = 0$, (b) $\alpha = 0.2\pi$, (c) $\alpha =$ 0.4π , and (d) $\alpha = 0.5\pi$. The high-symmetry points are $\Gamma =$ (0,0), $M = (0, \sqrt{2\pi}/\sqrt{3}a)$, and $K = (\sqrt{2\pi}/3a, \sqrt{2\pi}/\sqrt{3}a)$. The number of layers perpendicular to the surfaces is $L_{z'} =$ 31. The solid circles in (b) and (d) indicate the surface states in which the multipole density is evaluated in Figs. 9(a) and 9(b), respectively.

is large around the M point for even numbers of $L_{z'}$; therefore, we have chosen $L_{z'} = 31$. We observe the flat surface state isolated from the bulk band when the bulk band gap opens. In particular, for $\alpha = 0.5\pi$, the flat surface state extends in the entire Brillouin zone except on the lines where $w(\mathbf{k}_{\parallel})$ changes.

We can show that the surface state is completely localized on the first layer of the surface with a fully polarized octupole moment at K point, irrespective of the value of α . At other \mathbf{k}_{\parallel} , we need to evaluate the multipole density numerically.

FIG. 9. Multipole density in the surface state for a system with (111) surfaces (a) for $\alpha = 0.2\pi$ at $\mathbf{k}_{\parallel} = 0.9 \times K$ [see Fig. 8(b)] and (b) for $\alpha = 0.5\pi$ at $\mathbf{k}_{\parallel} = 0.4 \times K$ [see Fig. 8(d)]. The number of layers perpendicular to the surfaces is $L_{z'} = 31$, and $K = (\sqrt{2\pi}/3a, \sqrt{2\pi}/\sqrt{3}a)$.

FIG. 10. Octupole density on the top layer $i = (L_{z'} - 1)/2$ of the (111) surface in the surface state (a) for $\alpha = 0.2\pi$ and (b) for $\alpha = 0.5\pi$. The number of layers perpendicular to the surfaces is $L_{z'} = 101$.

We show the multipole density around the surfaces for $\alpha = 0.2\pi$ in Fig. 9(a) and for $\alpha = 0.5\pi$ in Fig. 9(b). The surface states are doubly degenerate, and we show the total multipole density of these two states. From the charge density Q(i), we recognize that these states are localized around the surfaces. $O_{20}(i)$ and $O_{22}(i)$ are zero for $\alpha = 0.5\pi$. The octupole moment $T_{xyz}(i)$ is opposite between the surfaces.

In Fig. 10, we show the octupole density on the top layer $i = (L_{z'} - 1)/2$ in the surface state. The octupole moment reaches unity at K point, irrespective of the value of α .

VI. SUMMARY AND DISCUSSION

We have investigated the surface states of an e_g orbital model on a simple cubic lattice. We find surface states with octupole moments on the (110) and (111) surfaces.

Concerning octupole moments, ordering of them has been observed in f-electron materials, such as NpO₂ [28, 30, 31, 47–51] and Ce_xLa_{1-x}B₆ [52–57]. In e_g orbital systems of d electrons, the possibility of octupole ordering in the bulk perovskite manganites has been theoretically explored [45, 58–60]. However, a theory that incorporates fluctuations beyond the mean-field approximation concluded that such ordering is improbable [39, 46, 61]. The present paper uncovers the potential for octupole moments to emerge on the surfaces of e_g orbital systems.

Another characteristic of the surface state is the region in which it appears. The flat surface state appears on the (111) surface across all surface momenta, provided the bulk band gap is open. This contrasts with the surface state of the single-orbital model on a diamond lattice with nearest-neighbor hopping, where the surface state emerges only in specific regions of the surface Brillouin zone [16].

As a candidate material, BaFeO₃ is promising [62]. This material crystallizes in the perovskite structure, with the Fe⁴⁺ ion possessing a $3d^4$ electron configuration. The ground state is ferromagnetic. Assuming the spins are fully polarized, the present spinless model can be applied to the half-filled e_g orbitals, while the wholly filled t_{2g} orbitals can be ignored.
