# **Abstract**

Bayesian optimization is a sample-efficient method for solving expensive, black-box optimization problems. Stochastic programming concerns optimization under uncertainty where, typically, average performance is the quantity of interest. In the first stage of a two-stage problem, here-and-now decisions must be made in the face of this uncertainty, while in the second stage, wait-and-see decisions are made after the uncertainty has been resolved. Many methods in stochastic programming assume that the objective is cheap to evaluate and linear or convex. In this work, we apply Bayesian optimization to solve non-convex, two-stage stochastic programs which are expensive to evaluate. We formulate a knowledgegradient-based acquisition function to jointly optimize the first- and second-stage variables, establish a guarantee of asymptotic consistency and provide a computationally efficient approximation. We demonstrate comparable empirical results to an alternative we formulate which alternates its focus between the two variable types, and superior empirical results over the standard, naïve, two-step benchmark. We show that differences in the dimension and length scales between the variable types can lead to inefficiencies of the two-step algorithm, while the joint and alternating acquisition functions perform well in all problems tested. Experiments are conducted on both synthetic and real-world examples.

# **1 Introduction**

Many optimization problems involve decisions that must be made without full information. This uncertainty can be handled in several ways depending on the risk appetite of the decision maker, ranging from optimizing for the worst-case outcome, to optimizing for average performance. The Bayesian optimization community refers to all these approaches as *robust* optimization problems, however, the wider optimization community usually reserve the term robust for worst-case optimization. Optimization of the average case is the default for *stochastic programming* [\(Birge & Louveaux, 2011;](#page-18-0) [Shapiro et al., 2021\)](#page-21-0).

The notion of a two-stage decision process was first introduced to stochastic programming by [Dantzig](#page-19-0) [\(1955\)](#page-19-0), who considered linear programs. In contrast, we consider non-convex problems, but the setting is otherwise the same.

We wish to maximize some function  $h(x, y, u)$ , whose value is dependent on a random variable  $u$  representing the uncertainty in the system. We wish to optimize this in the sense of expected performance,  $\mathbb{E}_{\mathbf{u}}[h(\mathbf{x}, \mathbf{y}, \mathbf{u})]$ . In the first stage of the optimization, we choose the *here-and-now* variables or *fixed design*, *x*, before the value

<span id="page-1-0"></span>

Figure 1: A contour plot for a non-convex two-stage stochastic optimization problem at three different values of the fixed design, x. The optimal second-stage decision,  $y = q(u)$ , is shown by the solid blue line. The aim is to find the fixed design with the best objective value after taking the expectation over the environmental variable.

taken by the uncertain variable **u** is known. In the second stage, we choose the *wait-and-see* or *adjustable variables*, **y**, which can depend on the value of **u**. Thus, the aim is to learn an optimal vector  $x$  and function  $y = g(u)$  to maximize the expected objective. This is illustrated in Figure [1.](#page-1-0)

Non-convex, two-stage stochastic programs arise throughout operations research and engineering, including in the design of wind farms [\(Chen et al., 2022\)](#page-19-1) and the management of power stations [\(Phan & Ghosh,](#page-21-1) [2014\)](#page-21-1). Similar problems are popular in optimal control, specifically in control co-design, where the objective is to jointly optimize a fixed plant design and a control signal in the presence of a *feedback loop*. Example applications include hybrid electric vehicles [\(Yan et al., 2020;](#page-22-0) [Xun et al., 2022\)](#page-22-1), batteries [\(Cui & Wang,](#page-19-2) [2021\)](#page-19-2) and wind turbines [\(Cui et al., 2021\)](#page-19-3).

In many of these problems, evaluating the objective is expensive. For example, it may require running time-consuming fluid dynamics or finite element analysis simulations, or be a physical experiment that not only takes time but consumes costly resources. It therefore pays to put more computational effort into reducing the number of evaluations required compared with a typical stochastic approximation approach with numerical gradients [\(Shapiro et al., 2021,](#page-21-0) Section 8.2). Bayesian optimization is a sample-efficient, global optimization technique designed to tackle such problems. A probabilistic model of the objective – usually a Gaussian process – is maintained, and an acquisition function is used to measure the value of collecting a sample at a proposed input.

We can naïvely apply Bayesian optimization to solve two-stage stochastic programs, by first optimizing the wait-and-see control policy  $y = g(u)$  for an arbitrary value of the fixed design x, then switching to optimize the fixed design for the control policy found in the first phase. The two phases could be alternated until convergence. However, each phase requires a new initial sample, waiting for each step to converge is wasteful and slow, and the iteration is not guaranteed to converge to the global optimum. There is therefore potential to improve greatly upon this by jointly optimizing both sets of variables.

In this paper, we formulate the knowledge gradient acquisition function for two-stage stochastic optimization problems without coupled constraints. We establish asymptotic consistency of the estimators of the maximum of the expected performance,  $\mathbb{E}_{\mathbf{u}}[h(\mathbf{x}^{*n}, \mathbf{g}^{*n}(\mathbf{u}), \mathbf{u})]$ , associated with the fixed design  $\mathbf{x}^{*n}$  and control policy *g*<sup>★*n*</sup> which would be recommended with this acquisition function after *n* iterations, under the assumption that the function *h* is drawn from a Gaussian process with known mean and covariance function. Further, we provide a computationally efficient approximation scheme to optimize this acquisition function and present an alternative algorithm which alternates its focus between the here-and-now and wait-and-see variables, making fewer approximations. We demonstrate empirically that both of these perform similarly on a suite of synthetic and real-world problems, with and without observation noise, and significantly outperform the standard 'two-step' algorithm which alternates between fully optimizing  $x$  and fully optimizing  $y = g(u)$ . Increasing the dimension of  $X$  and  $Y$  and decreasing the length scale of *h* makes different aspects of the problem harder and we investigate the effect of this on the three algorithms.

### <span id="page-2-2"></span>**1.1 Problem statement**

Let  $\mathbb{X} \subset \mathbb{R}^{d_x}$ ,  $\mathbb{Y} \subset \mathbb{R}^{d_y}$  and  $\mathbb{U} \subset \mathbb{R}^{d_u}$  denote the spaces of fixed, adjustable and environmental variables respectively. Let  $h : \mathbb{X} \times \mathbb{Y} \times \mathbb{U} \to \mathbb{R}$  be an unknown function and suppose that we can make expensive observations of *h* at points of our choosing  $(x, y, u) \in X \times Y \times U$ , possibly corrupted by Gaussian noise,

<span id="page-2-1"></span>
$$
\mathbf{v} = h(\mathbf{x}, \mathbf{y}, \mathbf{u}) + \varepsilon, \quad \varepsilon \sim \mathcal{N}(0, \sigma^2). \tag{1}
$$

This paper tackles the problem of finding fixed parameters  $x \in \mathbb{X}$  and a control policy  $g : \mathbb{U} \to \mathbb{Y}$  which maximize the expectation of *h* over the uncertain environment, **u**. That is, it solves

<span id="page-2-3"></span>
$$
\underset{\substack{\boldsymbol{x}\in\mathbb{X}\\\boldsymbol{g}:\mathbb{U}\to\mathbb{Y}}}{\arg\max} \mathbb{E}_{\mathbf{u}}\big[h(\boldsymbol{x},\boldsymbol{g}(\mathbf{u}),\mathbf{u})\big].\tag{2}
$$

We assume here that the distribution of **u** is known, say from historical observations, but we make no assumptions on what form that distribution takes.

Note that the problem can also be phrased in the classical manner as a stochastic bi-level optimization, by moving the optimization of *g* inside the expectation,

<span id="page-2-0"></span>
$$
\max_{\boldsymbol{x}\in\mathbb{X}}\mathbb{E}_{\mathbf{u}}\big[h^{\ast}(\boldsymbol{x},\mathbf{u})\big]
$$
(3a)

where 
$$
\forall \mathbf{x} \in \mathbb{X} \forall \mathbf{u} \in \mathbb{U} \ h^*(\mathbf{x}, \mathbf{u}) = \max_{\mathbf{y} \in \mathbb{Y}} h(\mathbf{x}, \mathbf{y}, \mathbf{u}).
$$
 (3b)

Any constraints on x and y are assumed part of the definition of X and Y. We do not consider coupled constraints where the space Y of admissible *y* depends on *x*, nor when either of X and Y depend on **u**.

Throughout this paper, we use an italic font, *u*, to represent deterministic quantities and a straight font, **u**, for random vectors. The exception to this are Greek letters, such as the observation noise  $\varepsilon$ , and the Gaussian process, *f*, to be introduced later.

#### **1.2 Related work**

For worst-case robustness, the two-stage problem is known as *adjustable robust optimization* [\(Ben-Tal et al.,](#page-18-1) [2004;](#page-18-1) [Poursoltani & Delage, 2021\)](#page-21-2). Solution methods generally focus on finding explicit functional forms for the control policy (or 'decision rule') and objectives are usually linear. [Yanıkoğlu et al.](#page-22-2) [\(2019\)](#page-22-2) observe that the case of nonlinear objectives is under-studied. A highly related concept is that of *recoverable robustness* [Liebchen et al.](#page-20-0) [\(2009\)](#page-20-0), where the aim is to optimize a deterministic objective and find a computationally feasible 'recovery algorithm' to modify the solution to ensure that scenario-dependent constraints are satisfied. The recovery algorithm takes the place of the control policy in adjustable robustness. Again, most solution methods target linear problems. A third concept is that of *distributional robustness*, where the objective is now an expectation over the environmental variables, but the distribution of these variables is not well understood and the worst case over plausible distributions is considered. Again, the literature tends to focus on linear problems [\(Bertsimas et al., 2021\)](#page-18-2).

The problem of *control co-design (CCD)* is very similar to two-stage stochastic optimization, and tackles nonconvex problems. The role of the uncertain variables **u** is replaced by a state vector evolving deterministically according to a difference or differential equation. The search over adjustable variables, **y**, is replaced with a search for an optimal control signal as a function of time, which can affect the state evolution. [Wauters](#page-22-3) [et al.](#page-22-3) [\(2022\)](#page-22-3) apply Bayesian optimization in the outer loop of a nested optimization scheme to solve the deterministic CCD problem. [Azad & Herber](#page-18-3) [\(2023\)](#page-18-3) review different ways of introducing uncertainty into the CCD problem, the closest of which to the problem tackled in this paper is *stochastic in expectation, uncertain*

*CCD (SE-UCCD)*. [Azad & Herber](#page-17-0) [\(2022\)](#page-17-0) use a nested formulation along with Monte Carlo simulation and generalized polynomial chaos expansions to solve an SE-UCCD problem. The authors note a nested scheme is necessary to decouple the optimization of the control variables for different realizations of the uncertainty.

Non-convex, two-stage stochastic optimization problems are a class of uncertain bi-level optimization problem where the inner and outer objectives are identical. Many more sources of uncertainty are possible in this setup beyond the uncertainty from **u**, arising when the first and second level decision makers do not know how each other will react [\(Beck et al., 2023\)](#page-18-4). Bayesian optimization with the UCB acquisition function has been applied to bi-level problems in [\(Fu et al., 2024\)](#page-19-4), while a surrogate-assisted evolutionary algorithm was employed in [\(Sinha & Shaikh, 2022\)](#page-21-3) for bi-level problems.

[Salomon](#page-21-4) [\(2019\)](#page-21-4) explore non-convex, two-stage optimization problems under uncertainty under the name *active robust optimization*. Various risk measures are considered, including expectation, worst-case performance, value-at-risk, and target-based. Both single-objective and multi-objective problems are considered, and evolutionary algorithms are proposed for the multi-objective case.

Finally, we come to Bayesian optimization. To the best of the authors' knowledge, two-stage stochastic optimization problems have not yet been tackled with Bayesian optimization. However, the problem is closely related to both standard stochastic optimization (the first-stage decision) and multi-task optimization (the second-stage decision).

Robust Bayesian optimization aims to solve  $\max_{x \in \mathbb{X}} \mathbb{E}_{\mathbf{u}}[h(x, \mathbf{u})]$  and has received a lot of attention, with authors proposing acquisition strategies based on expected improvement [Williams et al.](#page-22-4) [\(2000\)](#page-22-4); [Groot et al.](#page-20-1) [\(2010\)](#page-20-1) and knowledge gradient [\(Pearce & Branke, 2017;](#page-21-5) [Pearce et al., 2022;](#page-21-6) [Toscano-Palmerin & Frazier,](#page-22-5) [2022\)](#page-22-5) to name a few. The related problem of robustness to perturbed or noisy inputs has also received much attention [\(Nogueira et al., 2016;](#page-20-2) [Beland & Nair, 2017;](#page-18-5) [Oliveira et al., 2019;](#page-20-3) [Fröhlich et al., 2020;](#page-19-5) [Le](#page-20-4) [& Branke, 2021;](#page-20-4) [2024\)](#page-20-5), as has the study of other risk measures such as value-at-risk [\(Cakmak et al., 2020;](#page-19-6) [Daulton et al., 2022\)](#page-19-7) and mean-variance trade-offs [\(Qing et al., 2022\)](#page-21-7). Generally, it is assumed that the distribution of the environmental variables is known, but recent work exists to infer this distribution [\(Huang](#page-20-6) [et al., 2024\)](#page-20-6).

In multi-task Bayesian optimization, the goal is to solve a finite set, or continuum of optimization problems, parameterized by *u*. This amounts to finding the control policy that optimizes the inner part of Equation [\(3\)](#page-2-0),  $\max_{\mathbf{g}: \mathbb{U} \to \mathbb{Y}} \mathbb{E}_{\mathbf{u}}[h(\mathbf{g}(\mathbf{u}), \mathbf{u})] = \mathbb{E}_{\mathbf{u}}[\max_{\mathbf{y} \in \mathbb{Y}} h(\mathbf{y}, \mathbf{u})].$  Acquisition functions based on entropy [\(Swersky et al.,](#page-22-6) [2013\)](#page-22-6), expected improvement [\(Tesch et al., 2011;](#page-22-7) [Ginsbourger et al., 2014\)](#page-20-7) and knowledge gradient [\(Pearce](#page-21-8) [& Branke, 2018;](#page-21-8) [Ding et al., 2022\)](#page-19-8) have been proposed previously.

# **2 Background**

In this section, we introduce the relevant background material from the field of Bayesian optimization for the case of single-stage, deterministic problems,  $h : \mathbb{X} \to \mathbb{R}$ . These will be generalized to two-stage stochastic problems in Section [3.](#page-5-0)

#### **2.1 Gaussian processes**

A *Gaussian process (GP)* on  $X \subset \mathbb{R}^d$  is a collection of random variables  $(f(\boldsymbol{x}) : \boldsymbol{x} \in X)$  such that for every finite subset  $\{\boldsymbol{x}^1,\ldots,\boldsymbol{x}^n\}\subset\mathbb{X}$ , the variables  $f(\boldsymbol{x}^1),\ldots,f(\boldsymbol{x}^n)$  are jointly normal. Their mean and covariance are given by a mean function  $\mu : \mathbb{X} \to \mathbb{R}$  and a covariance function, or kernel,  $k : \mathbb{X} \times \mathbb{X} \to [0, \infty)$ . These functions completely determine the finite-dimensional distributions of the GP, and we write  $f \sim \mathcal{GP}(\mu, k)$ .

Suppose we have made *n* noisy observations of the Gaussian process,  $v^1 = f(x^1) + \varepsilon^1, \ldots, v^n = f(x^n) + \varepsilon^n$ for independent  $\varepsilon^1, \ldots, \varepsilon^n \sim \mathcal{N}(0, \sigma^2)$ . Then the posterior distribution of *f* conditional on these observations is again a Gaussian process whose mean and covariance functions we shall denote by  $\mu^n$  and  $k^n$ .

When used to model an unknown function, the prior mean and covariance functions of a GP should be chosen to fit the function being modelled. Popular choices for the covariance function include the squared exponential kernel and Matérn family of kernels. These are parameterized by a length scale for each dimension

and an output scale. The mean function is often chosen to be zero or a constant. The length scales, output scale and constant mean, together with the variance of the observation noise are known as hyperparameters of the GP. They can be fitted by placing prior distributions on the hyperparameters and using maximum a posteriori (MAP) estimates. [Rasmussen & Williams](#page-21-9) [\(2006\)](#page-21-9) provide an excellent introduction to Gaussian processes for machine learning.

#### **2.2 Bayesian optimization**

Bayesian optimization is a technique for efficiently solving expensive, black-box, global optimization problems,  $h : \mathbb{X} \to \mathbb{R}$ . Initially, h is evaluated on a space-filling design such as a scrambled Sobol' sequence [\(Sobol', 1967\)](#page-21-10) or Latin hypercube (LHC) [\(McKay et al., 2000\)](#page-20-8). Afterward, additional samples are collected either one by one or in small batches, focusing on the more promising regions of the input space.

At each step, a Bayesian model is placed on the objective function and an acquisition function,  $\alpha : \mathbb{X} \to \mathbb{R}$ , is optimized to select the next sample location,  $x^{n+1} \in X$ . Typically, it is assumed that X is compact and  $\alpha$ is continuous at all but finitely many locations, so that it has a well-defined maximum in X.

The role of  $\alpha$  is to balance exploration of regions of the input space with high uncertainty, and exploitation of regions already known to contain good values. Most commonly, the Bayesian model consists of a Gaussian process (GP) prior, along with an observation model with additive Gaussian observation noise such as Equation [\(1\)](#page-2-1).

When the evaluation budget is exhausted a recommendation is returned, for which common choices are the best input evaluated so far (a risk-averse approach) or the maximum of the posterior mean of the GP (a risk-neutral approach).

Algorithm [1](#page-5-1) summarizes the Bayesian optimization algorithm to maximize a function  $h : \mathbb{X} \to \mathbb{R}$  using the knowledge gradient acquisition function. The review papers by [Shahriari et al.](#page-21-11) [\(2016\)](#page-21-11) and [Frazier](#page-19-9) [\(2018\)](#page-19-9), and the book by [Garnett](#page-20-9) [\(2023\)](#page-20-9) all provide a good introduction to Bayesian optimization.

#### **2.3 Knowledge gradient**

A popular acquisition function capable of handling observation noise and partial information is the knowledge gradient [\(Frazier et al., 2009;](#page-19-10) [Scott et al., 2011\)](#page-21-12). The grounding principle is that at the end of the data collection process, the recommended solution will be the maximum of the posterior mean. Write  $\mathbb{E}_n$  for expectation conditional on the *n* observations made during the optimization, and let  $\mu^n(\mathbf{x}) = \mathbb{E}_n[f(\mathbf{x})]$  be the posterior mean of the GP conditional on these observations. The final recommendation is

<span id="page-4-0"></span>
$$
x^{*n} = \underset{\mathbf{x} \in \mathbb{X}}{\arg \max} \mu^n(\mathbf{x}). \tag{4}
$$

The knowledge gradient acquisition function is then constructed to be one-step Bayes-optimal. That is, maximizing it corresponds to maximizing  $\mathbb{E}_n[f(\mathbf{x}^{*(n+1)})],$  where here the expectation is taken over both *f* and the next observation. Let  $v^{n+1} = f(x^{n+1}) + \varepsilon^{n+1}$  be the random variable representing the next observation. The knowledge gradient is given by

<span id="page-4-1"></span>
$$
\alpha_{\text{KG}}^n(\boldsymbol{x}) = \mathbb{E}_{\mathbf{v}^{n+1}} \left[ \max_{\boldsymbol{x}' \in \mathbb{X}} \mu^{n+1}(\boldsymbol{x}') \, \middle| \, \boldsymbol{x}^{n+1} = \boldsymbol{x} \right] - \max_{\boldsymbol{x}' \in \mathbb{X}} \mu^n(\boldsymbol{x}'). \tag{5}
$$

This is the expected change in the maximum of the posterior mean after making an additional observation at *x*.

#### <span id="page-4-2"></span>**2.4 Discrete approximation of knowledge gradient**

Optimizing the knowledge gradient on line [4](#page-5-2) of Algorithm [1](#page-5-1) is a non-trivial task [Ungredda et al.](#page-22-8) [\(2022\)](#page-22-8).

One long-standing method is to replace the search space for the inner optimizations with a finite approximation,  $\mathbb{X}_{\text{disc}} \subset \mathbb{X}$ . Then the outer expectation can either be computed analytically [\(Frazier et al., 2009,](#page-19-10) Algorithm 2) or via a quasi-Monte Carlo approximation, which is the approach taken in this paper.

#### <span id="page-5-1"></span>**Algorithm 1** Bayesian optimization using knowledge gradient

**Input:** Initial sample size  $n_0$ , evaluation budget  $n_{\text{tot}}$ 

- 1: Evaluate  $h$  at  $n_0$  points, chosen according to a space-filling design
- 2: **for**  $n = n_0$  **to**  $n_{\text{tot}} 1$  **do**
- 3: Fit hyperparameters of GP prior,  $f \sim \mathcal{GP}(\mu, k)$ , using MAP estimates and all available data
- 4: Optimize acquisition function,  $x^{n+1} \leftarrow \arg \max_{x} \alpha_{\text{KG}}^n(x)$
- 5: Evaluate expensive function,  $v^{n+1} \leftarrow h(x^{n+1}) + \varepsilon^{n+1}$
- 6: **end for**

7: Fit hyperparameters of GP prior,  $f \sim \mathcal{GP}(\mu, k)$ , using MAP estimates and all available data

8: Compute recommendation  $\mathbf{x}^{*n_{\text{tot}}} \leftarrow \arg \max_{\mathbf{x}} \mu^{n_{\text{tot}}}(\mathbf{x})$ 

**Output:** Recommendation, *x* ∗*n*tot

Write  $\mu^{n+1}(\mathbf{x}'; \mathbf{x}, v)$  for the posterior mean after  $n+1$  samples, where the  $(n+1)$ <sup>th</sup> sample is *v* and made at location *x*. Conditional on the *n* observations made so far, the  $(n + 1)$ <sup>th</sup> observation,  $v^{n+1} = f(x) + \varepsilon^{n+1}$ , is normally distributed,  $v^{n+1} | x^1, v^1, \ldots, x^n, v^n \sim \mathcal{N}(\mu^n(x), k^n(x, x) + \sigma^2)$ . Let  $\tilde{v}^{n+1,1}, \ldots, \tilde{v}^{n+1,N_v}$  be a quasi-Monte Carlo sample of  $v^{n+1}$ , of size  $N_v$ . Then

<span id="page-5-3"></span>
$$
\alpha_{\text{KG}}^n(\boldsymbol{x}) \approx \hat{\alpha}_{\text{KG}}^n(\boldsymbol{x}) = \frac{1}{N_v} \sum_{i=1}^{N_v} \max_{\boldsymbol{x}' \in \mathbb{X}_{\text{disc}}} \mu^{n+1}(\boldsymbol{x}'; \boldsymbol{x}, \tilde{v}^{n+1,i}) - \max_{\boldsymbol{x}' \in \mathbb{X}_{\text{disc}}} \mu^n(\boldsymbol{x}'). \tag{6}
$$

Using the reparametrization trick [Kingma & Welling](#page-20-10) [\(2014\)](#page-20-10); [Wilson et al.](#page-22-9) [\(2017\)](#page-22-9), we can write this as

<span id="page-5-5"></span><span id="page-5-2"></span>
$$
\mathbf{v}^{n+1} = \mu^n(\mathbf{x}) + \mathbf{z}\sqrt{k^n(\mathbf{x}, \mathbf{x}) + \sigma^2} \tag{7}
$$

 $\mathbf{w}$  *N*ere  $\mathbf{z} \sim \mathcal{N}(0, 1)$ . Fixing  $N_v$  *base samples*,  $\tilde{z}^1, \ldots, \tilde{z}^{N_v}$ , of z allows us to differentiate the samples  $\{v^{n+1,i}\}_i$ in Equation  $(6)$  by the input  $x$ . Therefore, we can optimize the knowledge gradient with a deterministic, gradient-based optimizer such as multi-start L-BFGS. A Monte Carlo approximation of an expression of the form  $\mathbb{E}_{z}[m(\bm{x}, z)]$  is known as sample average approximation (SAA) [\(Shapiro et al., 2021,](#page-21-0) Section 5.1).

Rather than using independent samples for the base samples, z, we instead use a scrambled Sobol' sequence to make Equation [\(6\)](#page-5-3) a quasi-Monte Carlo approximation. These base samples are randomly regenerated at each iteration of the Bayesian optimization loop, to avoid over-fitting to any particular set of samples.

# <span id="page-5-0"></span>**3 Knowledge gradient for two-stage problems**

We return now to the setting of two-stage stochastic optimization problems, as set out in the problem statement in Section [1.1.](#page-2-2)

Expected improvement [\(Jones et al., 1998\)](#page-20-11) is possibly the most common choice of acquisition function in Bayesian optimization. It compares the proposed sample location  $(x, y, u)$  with the best-tested value so far. However, in two-stage stochastic programming we are searching for a fixed design  $x \in X$  and control policy  $g: \mathbb{U} \to \mathbb{Y}$ , which maximizes the quantity  $\bar{f}(x,g) = \mathbb{E}_{\mathbf{u}}[f(x,g(\mathbf{u}),\mathbf{u})]$  as in Equation [\(2\)](#page-2-3). Expected improvement does not readily generalize to this problem because we are making evaluations of *f* rather than ¯*f* - a problem of observations giving partial information. This problem also occurs in robust and multi-task Bayesian optimization, where variants of expected improvement have been proposed [\(Williams et al., 2000;](#page-22-4) [Groot et al., 2010;](#page-20-1) [Tesch et al., 2011;](#page-22-7) [Ginsbourger et al., 2014\)](#page-20-7). The knowledge gradient acquisition function has also been used to tackle problems of partial information in multi-fidelity and multi-objective optimization and the optimization of function networks [\(Daulton et al., 2023;](#page-19-11) [Buckingham et al., 2023;](#page-18-6) [Buathong et al.,](#page-18-7) [2024\)](#page-18-7), and is arguably a simpler way to handle partial information. This is the approach taken in this paper.

Given a Gaussian process (GP) model  $f \sim GP(\mu, k)$  of the objective h and its expectation  $\overline{f}$  over a random **u**, write  $\bar{\mu}^n(x,g) = \mathbb{E}_n[\bar{f}(x,g)]$  for the posterior mean of  $\bar{f}$  after *n* observations of *f*. Then, by analogy with Equation [\(4\)](#page-4-0), after *n* observations we would recommend a fixed design and control strategy given by

<span id="page-5-4"></span>
$$
\boldsymbol{x}^{*n}, \boldsymbol{g}^{*n} = \arg\max_{\boldsymbol{x} \in \mathbb{X} \atop \boldsymbol{g}: \mathbb{U} \to \mathbb{Y}} \bar{\mu}^n(\boldsymbol{x}, \boldsymbol{g}).\tag{8}
$$

Writing  $\tilde{x} = (x, y, u)$  for brevity, the equivalent of Equation [\(5\)](#page-4-1) gives what we call the *joint knowledge gradient (jKG)*,

<span id="page-6-1"></span>
$$
\alpha_{jKG}^{n}(\tilde{x}) = \mathbb{E}_{v^{n+1}} \left[ \max_{\substack{x' \in \mathbb{X} \\ \mathcal{G}': \mathbb{U} \to \mathbb{Y}}} \bar{\mu}^{n+1}(x', g') \middle| \tilde{x}^{n+1} = \tilde{x} \right] - \max_{\substack{x' \in \mathbb{X} \\ \mathcal{G}': \mathbb{U} \to \mathbb{Y}}} \bar{\mu}^{n}(x', g') \tag{9}
$$
\n
$$
\text{Maximum of posterior mean} \\ \text{after next observation, } v^{n+1} \qquad \text{Current maximum of posterior mean} \\ \text{mean (constant wt } \tilde{x}) \qquad \qquad (9)
$$

where now  $v^{n+1} = f(x^{n+1}, y^{n+1}, u^{n+1}) + \varepsilon^{n+1}$  is the next observation (a random variable).

As has been pointed out in previous works, the second term here is constant and can be neglected when optimizing the knowledge gradient. However, as proved in Lemma [3.1,](#page-6-0)  $\alpha_{jKG}^{n}$  is non-negative, which can be used to improve the choice of initial locations when optimizing it. Therefore, in our experiments, we do not neglect the constant second term.

<span id="page-6-0"></span>**Lemma 3.1.** *The joint knowledge gradient is non-negative,*

$$
\forall \tilde{x} \in \mathbb{X} \times \mathbb{Y} \times \mathbb{U} \quad \alpha_{jKG}^n(\tilde{x}) \geq 0.
$$

This result is proved in Proposition [A.4](#page-25-0) in Appendix [A.](#page-22-10)

#### <span id="page-6-3"></span>**3.1 Asymptotic consistency of the recommendations as estimators of the supremum**

It is desirable to know that when using the joint knowledge gradient as an acquisition function, the value,  $\overline{h}(\bm{x}^{*n},\bm{g}^{*n}) = \mathbb{E}_{\mathbf{u}}[h(\bm{x}^{*n},\bm{g}^{*n}(\mathbf{u}),\mathbf{u})],$  of the solution recommended after *n* samples converges to the true maximum,  $\overline{h}(\mathbf{x}^*, \mathbf{g}^*) = \mathbb{E}_{\mathbf{u}}[h(\mathbf{x}^*, \mathbf{g}^*(\mathbf{u}), \mathbf{u})],$  as the number of samples tends to infinity. [Bect et al.](#page-18-8) [\(2019\)](#page-18-8) established almost sure convergence with knowledge gradient in the vanilla Bayesian optimization case assuming that the hyperparameters of the Gaussian process surrogate model remain fixed. With the same assumption on the hyperparameters, [Toscano-Palmerin & Frazier](#page-22-5) [\(2022\)](#page-22-5) showed convergence of the expected values in the risk-neutral, single-stage, stochastic setting if the environmental variable space, U, is finite. The following consistency result extends that found in [\(Bect et al., 2019\)](#page-18-8) to the case of two-stage stochastic optimization.

<span id="page-6-2"></span>**Theorem 3.2.** *Suppose that the objective, h, is a sample from a Gaussian process on*  $\mathbb{X} \times \mathbb{Y} \times \mathbb{U}$ *, and that*  $\mathbb{X}, \mathbb{Y}, \mathbb{U}$  are compact subsets of  $\mathbb{R}^{d_x}, \mathbb{R}^{d_y}, \mathbb{R}^{d_u}$ , respectively. Assume further that the surrogate  $f \sim \mathcal{GP}(\mu, k)$ *has the same hyperparameters as h so that we may identify*  $f = h$ . Then, viewing the recommendations  $\mathbf{x}^{*n}$ *and* **g** <sup>∗</sup>*<sup>n</sup> as random elements depending on the initial sample, the observation noise, and the function f, we have*

$$
\overline{f}(\mathbf{x}^{*n}, \mathbf{g}^{*n}) \to \sup_{\substack{\mathbf{x} \in \mathbb{X} \\ \mathbf{g} : \mathbb{U} \to \mathbb{Y}}} \overline{f}(\mathbf{x}, \mathbf{g}) \qquad as \qquad n \to \infty
$$

*almost surely and in mean.*

The proof of this theorem can be found in Appendix [A](#page-22-10) and is based on the work by [Bect et al.](#page-18-8) [\(2019\)](#page-18-8) and [Buckingham et al.](#page-18-6) [\(2023\)](#page-18-6). It begins by showing that the joint knowledge gradient converges almost surely, uniformly to zero. Further, the posterior mean and covariance of  $\bar{f}$  are shown to converge uniformly to continuous limits by observing that the posterior mean and covariance of *f* are martingales in Banach spaces. These two facts are combined to show that the uniform limit,  $\bar{\mu}^{\infty}$ , of the posterior means,  $\bar{\mu}^n$ , has sample paths which are almost surely equal to the sample paths of  $\overline{f}$  (up to a constant). Whence, convergence of the values of the recommendations can be established.

#### **3.2 Bi-level formulation**

Performing optimizations over a function space is a daunting task. By making use of the bi-level formulation introduced in Equation [\(3\)](#page-2-0), we obtain more tractable expressions. Indeed, by exchanging the order of  $\mathbb{E}_{v^{n+1}}$ 

and  $\mathbb{E}_{\mathbf{u}}$ , and moving the maximization over *g* inside the expectation over **u** in Equation [\(8\)](#page-5-4), we obtain

<span id="page-7-2"></span><span id="page-7-0"></span>
$$
\boldsymbol{x}^{*n} \in \arg\max_{\boldsymbol{x} \in \mathbb{X}} \mathbb{E}_{\mathbf{u}} \Big[ \max_{\mathbf{y} \in \mathbb{Y}} \mu^n(\boldsymbol{x}, \mathbf{y}, \mathbf{u}) \Big], \tag{10a}
$$

$$
\forall \mathbf{u} \in \mathbb{U} \quad \mathbf{g}^{*n}(\mathbf{u}) \in \arg\max_{\mathbf{y} \in \mathbb{Y}} \mu^n(\mathbf{x}^{*n}, \mathbf{y}, \mathbf{u}), \tag{10b}
$$

where  $\mu^{n}(\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{u}) = \mathbb{E}_{n}[f(\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{u})]$  is the posterior mean of the Gaussian process model.

Performing the same manipulation to Equation [\(9\)](#page-6-1) gives

<span id="page-7-1"></span>
$$
\alpha_{jKG}^{n}(\tilde{x}) = \mathbb{E}_{v^{n+1}} \left[ \underbrace{\max_{\mathbf{x}' \in \mathbb{X}} \mathbb{E}_{\mathbf{u}'} \left[ \max_{\mathbf{y}' \in \mathbb{Y}} \mu^{n+1}(\mathbf{x}', \mathbf{y}', \mathbf{u}') \right]}_{\text{Maximum of posterior mean}} \right] \tilde{x}^{n+1} = \tilde{x} \right] - \underbrace{\max_{\mathbf{x}' \in \mathbb{X}} \mathbb{E}_{\mathbf{u}'} \left[ \max_{\mathbf{y}' \in \mathbb{Y}} \mu^{n}(\mathbf{x}', \mathbf{y}', \mathbf{u}') \right]}_{\text{Current maximum of posterior mean}}.
$$
\n(11)

#### **3.3 Efficient computation and optimization**

Running a nested optimization is computationally expensive and slow. Instead, we propose a computational strategy based on successive discretization and quasi-Monte Carlo (qMC) approximation similar to that in Section [2.4.](#page-4-2) Specifically, we take discrete approximations  $\mathbb{X}_{disc}$  and  $\mathbb{Y}_{disc}$  in the inner maximizations over X and Y, and qMC approximations  $\mathbb{U}_{MC}$  and  $\mathbb{V}_{MC}$  for the expectations over  $\mathbf{u}' \in \mathbb{U}$  and  $v^{n+1} = f(\tilde{x}) + \varepsilon^{n+1} \in \mathbb{R}$ . The samples of  $v^{n+1}$  are taken conditional on the *n* observations made so far. In order to be able to differentiate the samples  $v \in V_{MC}$  by the proposed next query location  $\tilde{x}$ , we use the reparametrization trick as described in Equation [\(7\)](#page-5-5) to write each  $v = v(\tilde{x}, z)$  as a function of  $\tilde{x}$  and a corresponding base sample  $z \in \mathbb{V}_{\text{MC}}^{\text{base}}$ , where  $\mathbb{V}_{\text{MC}}^{\text{base}}$  is a Sobol' qMC approximation of a standard normal variable. Analogously to Equation [\(6\)](#page-5-3), write  $\mu^{n+1}(\mathbf{x}', \mathbf{y}', \mathbf{u}'; \tilde{\mathbf{x}}, v(\tilde{\mathbf{x}}, z))$  for the posterior mean of  $f(\mathbf{x}', \mathbf{y}', \mathbf{u}')$  after  $n+1$  samples, where the  $(n + 1)$ <sup>th</sup> sample is  $v(\tilde{x}, z)$  and made at location  $\tilde{x}$ . Then, writing  $N_v = |\mathbb{V}_{MC}| = |\mathbb{V}_{MC}^{base}|$  and  $N_u = |U_{MC}|$  for the sizes of the qMC approximation sets, this gives

$$
\alpha_{jKG}^{n}(\tilde{x}) \approx \hat{\alpha}_{jKG}^{n}(\tilde{x}) = \frac{1}{N_v} \sum_{z \in \mathbb{V}_{MC}^{base}} \max_{\mathbf{x}' \in \mathbb{X}_{disc}} \frac{1}{N_u} \sum_{\mathbf{u}' \in \mathbb{U}_{MC}} \max_{\mathbf{y}' \in \mathbb{Y}_{disc}} \mu^{n+1}(\mathbf{x}', \mathbf{y}', \mathbf{u}'; \tilde{x}, v(\tilde{x}, z)) - \underbrace{-\max_{\mathbf{x}' \in \mathbb{X}_{disc}} \frac{1}{N_u} \sum_{\mathbf{u}' \in \mathbb{U}_{MC}} \max_{\mathbf{y}' \in \mathbb{Y}_{disc}} \mu^{n}(\mathbf{x}', \mathbf{y}', \mathbf{u}') . \tag{12}
$$
constant wrt  $\tilde{x}$ 

As written, this is a SAA over both the environmental variable **u** and the base samples for the next observation  $v^{n+1}$ . It is differentiable by the proposed query location  $\tilde{x}$  and thus we can optimize  $\alpha_{jKG}^n(\tilde{x})$  using a gradientbased optimizer such as multi-start L-BFGS-B.

In order to speed up optimization of the acquisition function, it is important to cache some covariances that are not cached by default in GPyTorch at the time of writing. See Appendix [B](#page-33-0) for details on the caching and Appendix [C](#page-34-0) for a description of the choice of starts for the multi-start L-BFGS-B.

The discretizations  $\mathbb{X}_{disc}$  and  $\mathbb{Y}_{disc}$ , and qMC approximations  $\mathbb{U}_{MC}$  and  $\mathbb{V}_{MC}^{base}$  are chosen randomly and independently at each iteration to avoid over-fitting to a particular discretization. Samples from a random Latin hypercube (LHC) are used for  $\mathbb{X}_{disc}$  and  $\mathbb{Y}_{disc}$ , while samples of a scrambled Sobol' sequence are used for  $\mathbb{U}_{\text{MC}}$  and  $\mathbb{V}_{\text{MC}}^{\text{base}}$ .

When the evaluation budget is exhausted, a final recommendation must be given. This is computed by generating a further Sobol' sample UMC*,*rec and optimizing

<span id="page-7-4"></span><span id="page-7-3"></span>
$$
\boldsymbol{x}^{*n} \approx \hat{\boldsymbol{x}}^{*n} \in \operatorname*{arg\,max}_{\boldsymbol{x} \in \mathbb{X}} \sum_{\boldsymbol{u} \in \mathbb{U}_{\mathrm{MC},\mathrm{rec}}}\max_{\boldsymbol{y} \in \mathbb{Y}} \mu^{n}(\boldsymbol{x},\boldsymbol{y},\boldsymbol{u}).\tag{13}
$$

The optimal control policy is the function  $g^{*n}(u) \approx \hat{g}^{*n}(u) \in \arg \max_{y} \mu^{n}(\hat{x}^{*n}, y, u)$ . The optimization of  $\hat{x}^{*n}$  is done with multi-start L-BFGS-B in a fashion similar to the one-shot knowledge gradient [\(Balandat](#page-18-9)

[et al., 2020\)](#page-18-9), while the optimization within  $\hat{g}^*$  is done using single-start L-BFGS-B. Care must be taken over the choice of starts for the optimization of  $\hat{x}^{*n}$  since many local optima exist in the landscape. See Appendix [D](#page-35-0) for full details.

Algorithm [2](#page-8-0) shows the full Bayesian optimization loop for the joint knowledge gradient acquisition function. Hyperparameters are fitted at each step using maximum a posteriori (MAP) estimates with the exception of the prior mean, which is fitted only on the first iteration to avoid any bias from collecting samples near the optimum. Further details are given in Appendix [E.3.](#page-38-0)

<span id="page-8-0"></span>**Algorithm 2** Bayesian optimization for two-stage stochastic programs using the joint knowledge gradient

**Input:** Initial sample size  $n_0$ , evaluation budget  $n_{\text{tot}}$ , discretization sizes  $N_x$  and  $N_y$ , qMC sample sizes  $N_u$ , *N<sup>v</sup>* and *Nu,*rec (powers of two)

1: Evaluate *h* at  $n_0$  points, chosen according to a scrambled Sobol' sequence on  $\mathbb{X} \times \mathbb{Y} \times \mathbb{U}$ 

```
2: for n = n_0 to n_{\text{tot}} - 1 do
```
- 3: Fit hyperparameters of GP prior,  $f \sim \mathcal{GP}(\mu, k)$ , as described in the text
- $4:$  Generate  $\mathbb{X}_{\text{disc}} \leftarrow \text{LHC}(N_x)$ ,  $\mathbb{Y}_{\text{disc}} \leftarrow \text{LHC}(N_y)$ ,  $\mathbb{U}_{\text{MC}} \leftarrow \text{Sobol}(N_u)$ ,  $\mathbb{V}_{\text{MC}}^{\text{base}} \leftarrow \text{Sobol}(N_v)$
- $\mathbf{b}: \quad \bm{x}^{n+1}, \bm{y}^{n+1}, \bm{u}^{n+1} \leftarrow \argmax_{\bm{x}, \bm{y}, \bm{u}} \hat{\alpha}_{\text{jKG}}^n(\bm{x}, \bm{y}, \bm{u}; \, \mathbb{X}_{\text{disc}}, \mathbb{Y}_{\text{disc}}, \mathbb{U}_{\text{MC}}, \mathbb{V}_{\text{MC}}^{\text{base}})$
- 6: Evaluate  $h(\boldsymbol{x}^{n+1}, \boldsymbol{y}^{n+1}, \boldsymbol{u}^{n+1})$  (expensive)
- 7: **end for**

8: Fit hyperparameters of GP prior,  $f \sim \mathcal{GP}(\mu, k)$ , using MAP estimates

9: Generate  $\mathbb{U}_{\text{MC,rec}} \leftarrow \text{Sobol}(N_{u,rec})$ 

 $\text{10: Optimize } \boldsymbol{x}^{*n_{\text{tot}}} \in \argmax_{\boldsymbol{x}} \frac{1}{N_{u,\text{rec}}} \sum_{\boldsymbol{u} \in \mathbb{U}_{\text{MC},\text{rec}}} \max_{\boldsymbol{y}} \mu^{n_{\text{tot}}}(\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{u})$ 

11: Let  $g^{*n_{\text{tot}}} : \mathbb{U} \to \mathbb{Y}$  given by  $g^{*n_{\text{tot}}}(\boldsymbol{u}) \in \arg \max_{\boldsymbol{y}} \mu^{n_{\text{tot}}}(\boldsymbol{x}^{*n_{\text{tot}}}, \boldsymbol{y}, \boldsymbol{u})$ **Output:** *x* ∗*n*tot *, g* ∗*n*tot

#### <span id="page-8-1"></span>**3.4 An alternative, alternating policy**

The optimization of the joint knowledge gradient policy requires several layers of approximation. Previous works on robust [\(Pearce & Branke, 2017;](#page-21-5) [Toscano-Palmerin & Frazier, 2022\)](#page-22-5) and multi-task [\(Pearce &](#page-21-8) [Branke, 2018\)](#page-21-8) knowledge gradient which have used a discrete approximation for the inner maximization have avoided the need for the quasi-Monte Carlo (qMC) approximation of the expectation over the next observation. The tricks used cannot be extended to our formulation of the joint KG acquisition function. However, we can implement it in an alternating strategy switching between a pair of acquisition functions that aim to improve the fixed design,  $x$ , and adjustable variables,  $y$ , separately. Both acquisition functions use a GP model of the objective as a function of the whole space  $X \times Y \times U$ , and rely on the knowledge gradient principle. Algorithm [3](#page-9-0) outlines the algorithm, and the two acquisition functions are explained in detail in the following two sections.

### **3.4.1 Improving the fixed design**

The acquisition function designed to improve the fixed design asks 'if we must choose the control policy *g* now but can make one more observation before choosing the fixed design *x*, how much will the next sample improve the maximum of the posterior mean, in expectation?'. While this is a less natural question than the one that motivates the joint strategy, it effectively reduces our problem to a standard stochastic optimization problem, for which we can apply similar techniques to existing robust knowledge gradient formulations using discretizations [\(Pearce & Branke, 2017;](#page-21-5) [Toscano-Palmerin & Frazier, 2022\)](#page-22-5). Note that when we recommend the final solution, we still use Equation [\(10\)](#page-7-0), making use of all information available.

Recall the definitions of the recommendations  $x^{*n}, g^{*n}$  in Equation [\(10\)](#page-7-0). The acquisition function is obtained from Equation [\(9\)](#page-6-1) and Equation [\(11\)](#page-7-1) by replacing the maximizations over  $g'$  with  $g^{*n}$  – the optimal policy

<span id="page-9-0"></span>**Algorithm 3** Bayesian optimization for two-stage stochastic programs using the alternating knowledge gradient

**Input:** Initial sample size  $n_0$ , evaluation budget  $n_{\text{tot}}$ , discretization sizes  $N_x$  and  $N_y$ , qMC sample sizes  $N_u$ and *Nu,*rec (powers of two)

1: Evaluate *h* at  $n_0$  points, chosen according to a scrambled Sobol' sequence on  $X \times Y \times U$ 

2: **for**  $n = n_0$  **to**  $n_{\text{tot}} - 1$  **do** 

- 3: Fit hyperparameters of GP prior,  $f \sim \mathcal{GP}(\mu, k)$ , as described in Appendix [E.3](#page-38-0)
- 4: Generate  $\mathbb{X}_{\text{disc}} \leftarrow \text{LHC}(N_x), \mathbb{Y}_{\text{disc}} \leftarrow \text{LHC}(N_y), \mathbb{U}_{\text{MC}} \leftarrow \text{Sobol}(N_u)$
- 5: **if** *n* even **then**
- $\begin{aligned} \text{for} \qquad & \boldsymbol{x}^{n+1}, \boldsymbol{y}^{n+1}, \boldsymbol{u}^{n+1} \leftarrow \argmax_{\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{u}} \hat{\alpha}_{\text{aKG-fix}}^{n}(\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{u}; \ \mathbb{X}_{\text{disc}}, \mathbb{Y}_{\text{disc}}, \mathbb{U}_{\text{MC}}) \end{aligned}$
- 7: **else**
- $\begin{aligned} \mathrm{s}\colon \qquad \boldsymbol{x}^{n+1},\boldsymbol{y}^{n+1},\boldsymbol{u}^{n+1} \leftarrow \argmax_{\boldsymbol{x},\boldsymbol{y},\boldsymbol{u}} \hat{\alpha}_{\mathrm{aKG\text{-}adj}}^n(\boldsymbol{x},\boldsymbol{y},\boldsymbol{u};\,\mathbb{X}_{\mathrm{disc}},\mathbb{Y}_{\mathrm{disc}},\mathbb{U}_{\mathrm{MC}}) \end{aligned}$
- 9: **end if**
- 10: Evaluate  $h(\mathbf{x}^{n+1}, \mathbf{y}^{n+1}, \mathbf{u}^{n+1})$  (expensive)
- 11: **end for**

12: Fit hyperparameters of GP prior,  $f ∼ \mathcal{GP}(\mu, k)$ , using MAP estimates

- 13: Generate  $\mathbb{U}_{\text{MC,rec}} \leftarrow \text{Sobol}(N_{u,rec})$
- $\text{14: Optimize } \boldsymbol{x^{*n_\text{tot}}} \in \argmax_{\boldsymbol{x}} \frac{1}{N_{u,\text{rec}}} \sum_{\boldsymbol{u} \in \mathbb{U}_{\text{MC},\text{rec}}} \max_{\boldsymbol{y}} \mu^{n_\text{tot}}(\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{u})$
- 15: Let  $g^{*n_{\text{tot}}} : \mathbb{U} \to \mathbb{Y}$  given by  $g^{*n_{\text{tot}}}(\boldsymbol{u}) \in \arg \max_{\boldsymbol{y}} \mu^{n_{\text{tot}}}(\boldsymbol{x}^{*n_{\text{tot}}}, \boldsymbol{y}, \boldsymbol{u})$
- Output:  $x^{*n_{\text{tot}}}, g^{*n_{\text{tot}}}$

before the next observation,

$$
\alpha_{\mathrm{aKG\text{-}fix}}^n(\tilde{\boldsymbol{x}}) = \mathbb{E}_{\mathbf{v}^{n+1}} \left[ \max_{\boldsymbol{x}' \in \mathbb{X}} \bar{\mu}^{n+1}(\boldsymbol{x}', \boldsymbol{g}^{*n}) \middle| \tilde{\boldsymbol{x}}^{n+1} = \tilde{\boldsymbol{x}} \right] - \max_{\boldsymbol{x}' \in \mathbb{X}} \bar{\mu}^n(\boldsymbol{x}', \boldsymbol{g}^{*n}) \qquad (14a)
$$
\n
$$
= \mathbb{E}_{\mathbf{v}^{n+1}} \left[ \max_{\boldsymbol{x}' \in \mathbb{X}} \mathbb{E}_{\mathbf{u}'} \left[ \mu^{n+1}(\boldsymbol{x}', \boldsymbol{g}^{*n}(\mathbf{u}'), \mathbf{u}') \right] \middle| \tilde{\boldsymbol{x}}^{n+1} = \tilde{\boldsymbol{x}} \right] - \max_{\boldsymbol{x}' \in \mathbb{X}} \mathbb{E}_{\mathbf{u}'} \left[ \mu^n(\boldsymbol{x}', \boldsymbol{g}^{*n}(\mathbf{u}'), \mathbf{u}') \right]. \quad (14b)
$$
\nMaximum of posterior mean

after next observation, 
$$
v^{n+1}
$$
,  
if we can only change  $x'$ 

This is approximated by

$$
\hat{\boldsymbol{x}}^{*n} \in \underset{\boldsymbol{x}' \in \mathbb{X}_{\text{disc}}}{\arg \max} \frac{1}{N_u} \sum_{\boldsymbol{u}' \in \mathbb{U}_{\text{MC}}} \max_{\boldsymbol{y}' \in \mathbb{Y}_{\text{disc}}} \mu^n(\boldsymbol{x}', \boldsymbol{y}', \boldsymbol{u}'),\tag{15a}
$$

<span id="page-9-2"></span><span id="page-9-1"></span>(constant wrt  $\tilde{x}$ )

$$
\forall \mathbf{u}' \in \mathbb{U}_{\mathrm{MC}} \quad \hat{\mathbf{g}}^{*n}(\mathbf{u}') \in \underset{\mathbf{y}' \in \mathbb{Y}_{\mathrm{disc}}}{\arg \max} \mu^{n}(\hat{\mathbf{x}}^{*n}, \mathbf{y}', \mathbf{u}'), \tag{15b}
$$

$$
\hat{\alpha}_{\text{aKG-fix}}^{n}(\tilde{\boldsymbol{x}}) = \mathbb{E}_{\mathbf{v}^{n+1}} \left[ \max_{\boldsymbol{x}' \in \mathbb{X}_{\text{disc}}} \frac{1}{N_u} \sum_{\boldsymbol{u}' \in \mathbb{U}_{\text{MC}}} \mu^{n+1}(\boldsymbol{x}', \hat{\boldsymbol{g}}^{*n}(\boldsymbol{u}'), \boldsymbol{u}') \right] \tilde{\boldsymbol{x}}^{n+1} = \boldsymbol{x} \right]
$$
\n
$$
- \frac{1}{N_u} \sum_{\boldsymbol{u}' \in \mathbb{U}_{\text{MC}}} \mu^{n}(\boldsymbol{x}', \hat{\boldsymbol{g}}^{*n}(\boldsymbol{u}'), \boldsymbol{u}'). \tag{15c}
$$

We observe that the posterior mean  $\mu^{n+1}(\cdot)$  varies linearly with  $v^{n+1}$  in Equation [\(15c\)](#page-9-1). Therefore, the expectation over  $v^{n+1}$  can be computed exactly using Algorithm 2 in [\(Frazier et al., 2009\)](#page-19-10), see [\(Pearce &](#page-21-5) [Branke, 2017;](#page-21-5) [Toscano-Palmerin & Frazier, 2022\)](#page-22-5). The resulting expression is deterministic and differentiable with respect to  $\tilde{x}$ , so can be optimized using a gradient-based optimizer such as multi-start L-BFGS-B.

#### **3.4.2 Improving the adjustable variables**

Complementing this, the acquisition function designed to improve the adjustable variables asks the question 'if we must choose the fixed design *x* now but can make one more observation before before choosing the control policy *g*, how much will the next sample improve the maximum of the posterior mean, in expectation?'. By pretending that the fixed design *x* cannot be changed, the problem is reduced to a multi-task optimization problem and we can apply the multi-task knowledge gradient strategy proposed in [\(Pearce & Branke, 2018\)](#page-21-8).

The acquisition function is obtained from Equation [\(9\)](#page-6-1) and Equation [\(11\)](#page-7-1) by replacing the maximizations over  $x'$  with  $x^{*n}$  from Equation [\(10a\)](#page-7-2),

$$
\alpha_{\rm aKG\text{-}adj}^{n}(\tilde{\boldsymbol{x}}) = \mathbb{E}_{\mathbf{v}^{n+1}} \left[ \max_{\boldsymbol{g}': \mathbb{U} \to \mathbb{Y}} \bar{\mu}^{n+1}(\boldsymbol{x}^{*n}, \boldsymbol{g}') \, \middle| \, \tilde{\boldsymbol{x}}^{n+1} = \tilde{\boldsymbol{x}} \right] \qquad - \max_{\boldsymbol{g}': \mathbb{U} \to \mathbb{Y}} \bar{\mu}^{n}(\boldsymbol{x}^{*n}, \boldsymbol{g}') \right]
$$
(16a)

$$
= \mathbb{E}_{v^{n+1}} \left[ \underbrace{\mathbb{E}_{\mathbf{u}'} \left[ \max_{\mathbf{y}' \in \mathbb{Y}} \mu^{n+1}(\mathbf{x}^{*n}, \mathbf{y}', \mathbf{u}') \right]}_{\text{Maximum of posterior mean}} \right] \left[ \tilde{\mathbf{x}}^{n+1} = \tilde{\mathbf{x}} \right] - \underbrace{\mathbb{E}_{\mathbf{u}'} \left[ \max_{\mathbf{y}' \in \mathbb{Y}} \mu^{n}(\mathbf{x}^{*n}, \mathbf{y}', \mathbf{u}') \right]}_{\text{Current maximum of posterior}}.
$$
 (16b)

Maximum of posterior mean<br>after next observation,  $v^{n+1}$ , if we can only change *y* ′

<span id="page-10-1"></span>Current maximum of posterior mean (constant wrt *x,y* and *u*)

It is approximated by

$$
\hat{\alpha}_{\text{aKG-adj}}^{n}(\tilde{\boldsymbol{x}}) = \frac{1}{N_{u}} \sum_{\boldsymbol{u}' \in \mathbb{U}_{\text{MC}}} \mathbb{E}_{\mathbf{v}^{n+1}} \left[ \max_{\boldsymbol{y}' \in \mathbb{Y}_{\text{disc}}} \underbrace{\mu^{n+1}(\hat{\boldsymbol{x}}^{*n}, \boldsymbol{y}', \boldsymbol{u}')}_{\text{varies linearly with } \mathbf{v}^{n+1}} \, \bigg| \, \tilde{\boldsymbol{x}}^{n+1} = \tilde{\boldsymbol{x}} \right] - \frac{1}{N_{u}} \sum_{\boldsymbol{u}' \in \mathbb{U}_{\text{MC}}} \max_{\boldsymbol{y}' \in \mathbb{Y}_{\text{disc}}} \mu^{n}(\hat{\boldsymbol{x}}^{*n}, \boldsymbol{y}', \boldsymbol{u}') \tag{17}
$$

where  $\hat{x}^{*n}$  is given by Equation [\(15a\)](#page-9-2). Again, the expectation over  $v^{n+1}$  can be computed exactly, the result is differentiable with respect to  $\tilde{x}$ , and the acquisition function can be optimized using a gradient-based optimizer such as multi-start L-BFGS-B.

#### <span id="page-10-0"></span>**3.5 The two-step incumbent method**

In the absence of co-design, the fixed design  $x$  and controller  $g$  must be designed separately. That is, engineers must alternate between the following two steps:

- 1. Fix the fixed design, *x*, and optimize the control strategy, *g*;
- 2. Fix the control strategy, *g*, and optimize the fixed design, *x*.

This is inefficient because it cannot be known up-front for how long to optimize each part of the design. For this reason, we consider a benchmark algorithm that only executes each step once and consider that future iterations of the steps would happen beyond the evaluation budget considered.

As in the previous sections, we employ the knowledge gradient acquisition function. In the first step, an  $x_{step-1} \in \mathbb{X}$  is chosen, the restriction of *h* to  $\{x_{step-1}\}\times\mathbb{Y}\times\mathbb{U}$  is modeled using a Gaussian process,  $f_{\text{step-1}} : \mathbb{Y} \times \mathbb{U} \to \mathbb{R}$ , and the knowledge gradient is maximized to select the *y* and *u* for the next observation. At the end of the first step, an optimal policy  $g^{*n_{\text{tot},1}}$  is extracted. In the second step, the restriction of *h* to  $\{(\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{u}) \in \mathbb{X} \times \mathbb{Y} \times \mathbb{U} : \boldsymbol{y} = \boldsymbol{g}^{*n}(\boldsymbol{u})\}$  is modeled with a Gaussian process,  $f_{\text{step-2}} : \mathbb{X} \times \mathbb{U} \to \mathbb{R}$ , and the knowledge gradient is maximized to select the *x* and *u* for the next observation. At the end of the second step, an optimal fixed design  $x^{*n_{\text{tot},2}}$  is extracted.

The two acquisition functions are

$$
\alpha_{2sKG-1}^{n}(\boldsymbol{y},\boldsymbol{u}) = \mathbb{E}_{\mathbf{v}_{step-1}^{n+1}} \Bigg[ \mathbb{E}_{\mathbf{u}'} \bigg[ \max_{\boldsymbol{y}' \in \mathbb{Y}} \mu_{step-1}^{n+1}(\boldsymbol{y}',\mathbf{u}') \bigg] \Bigg| (\boldsymbol{y}_{step-1}^{n+1}, \boldsymbol{u}_{step-1}^{n+1}) = (\boldsymbol{y}, \boldsymbol{u}) \Bigg] - \mathbb{E}_{\mathbf{u}'} \bigg[ \max_{\boldsymbol{y}' \in \mathbb{Y}} \mu_{step-1}^{n}(\boldsymbol{y}',\mathbf{u}') \bigg], \tag{18a}
$$

$$
\alpha_{2sKG\text{-}2}^n(\boldsymbol{x},\boldsymbol{u}) = \mathbb{E}_{\mathbf{v}_{step\text{-}2}^{n+1}} \Bigg[ \max_{\boldsymbol{x}' \in \mathbb{X}} \mathbb{E}_{\mathbf{u}'} \big[\mu_{step\text{-}2}^{n+1}(\boldsymbol{x}',\mathbf{u}')\big] \Bigg| (\boldsymbol{x}_{step\text{-}2}^{n+1}, \boldsymbol{u}_{step\text{-}2}^{n+1}) = (\boldsymbol{x}, \boldsymbol{u}) \Bigg] - \max_{\boldsymbol{x}' \in \mathbb{X}} \mathbb{E}_{\mathbf{u}'} \big[\mu_{step\text{-}2}^n(\boldsymbol{x}',\mathbf{u}')\big]. \tag{18b}
$$

Here, the hypothesized next observation is  $v_{step-1}^{n+1} = f_{step-1}(\mathbf{y}_{step-1}^{n+1}, \mathbf{u}_{step-1}^{n+1}) + \varepsilon_{step-1}^{n+1}$  in step one and  $v_{step-2}^{n+1} =$  $f_{\text{step-2}}(\boldsymbol{x}_{\text{step-2}}^{n+1}, \boldsymbol{u}_{\text{step-2}}^{n+1}) + \varepsilon_{\text{step-2}}^{n+1}$  in step two, where  $\varepsilon_{\text{step-1}}^{n+1}, \varepsilon_{\text{step-2}}^{n+1} \sim \mathcal{N}(0, \sigma^2)$  represent observation noise.

These are approximated similarly to the alternating algorithm from Section [3.4.](#page-8-1)

<span id="page-11-0"></span>
$$
\hat{\alpha}_{2sKG-1}^{n}(\boldsymbol{y},\boldsymbol{u}) = \frac{1}{N_{u}} \sum_{\boldsymbol{u}' \in \mathbb{U}_{MC}} \mathbb{E}_{\mathbf{v}_{step-1}^{n+1}} \left[ \max_{\boldsymbol{y}' \in \mathbb{Y}_{disc}} \mu_{step-1}^{n+1}(\boldsymbol{y}',\boldsymbol{u}') \middle| (\boldsymbol{y}_{step-1}^{n+1}, \boldsymbol{u}_{step-1}^{n+1}) = (\boldsymbol{y}, \boldsymbol{u}) \right] \n- \frac{1}{N_{u}} \sum_{\boldsymbol{u}' \in \mathbb{U}_{MC}} \max_{\boldsymbol{y}' \in \mathbb{Y}_{disc}} \mu_{step-1}^{n}(\boldsymbol{y}',\boldsymbol{u}'), \n\hat{\alpha}_{2sKG-2}^{n}(\boldsymbol{x},\boldsymbol{u}) = \mathbb{E}_{\mathbf{v}_{step-2}^{n+1}} \left[ \max_{\boldsymbol{x}' \in \mathbb{X}_{disc}} \frac{1}{N_{u}} \sum_{\boldsymbol{u}' \in \mathbb{U}_{MC}} \mu_{step-2}^{n+1}(\boldsymbol{x}',\boldsymbol{u}') \middle| (\boldsymbol{x}_{step-2}^{n+1}, \boldsymbol{u}_{step-2}^{n+1}) = (\boldsymbol{x}, \boldsymbol{u}) \right] \n- \max_{\boldsymbol{x}', \in \mathbb{X}_{disc}} \frac{1}{N_{u}} \sum_{\boldsymbol{u}' \in \mathbb{U}_{MC}} \mu_{step-2}^{n}(\boldsymbol{x}',\boldsymbol{u}').
$$
\n(19b)

As with the alternating algorithm, the expectations over  $v_{step-1}^{n+1}$  and  $v_{step-2}^{n+1}$  can be computed exactly using Algorithm 2 in [\(Frazier et al., 2009\)](#page-19-10), the result is deterministic and differentiable, and can be optimized using a gradient-based optimizer such as multi-start L-BFGS-B.

# <span id="page-11-1"></span>**4 Experiments**

To demonstrate the value of jointly optimizing the fixed design and adjustable variables, experiments are run on a variety of synthetic and real-world examples. Using the synthetic test problems sampled from Gaussian processes we avoid any issues due to model mismatch, investigate the effects of dimension and length scales, and demonstrate the ability of the algorithms to cope with observation noise. The example of optical table design shows that the joint and alternating knowledge gradient remain superior algorithms in real-world optimization landscapes.

In all experiments, the initial sample is a scrambled Sobol' sequence, whose size depends on the problem dimension and is detailed separately in Sections [4.2](#page-13-0) and [4.3.](#page-13-1)

The main algorithm in this paper, presented in Equation [\(12\)](#page-7-3), jointly optimizes the fixed design *x* and control strategy *g* and we refer to it as *joint KG (jKG)*. We refer to the alternating alternative from Section [3.4](#page-8-1) as *alternating KG (aKG)* and the two-step incumbent from Section [3.5](#page-10-0) as *two-step KG (2sKG)*. In addition to comparing the three knowledge gradient algorithms, we also compare with a joint and a two-step random sampling policy, which we call *joint RS (jRS)* and *two-step RS (2sRS)* respectively. These policies use the same models and recommendation procedures as the joint and two-step knowledge gradient but recommend samples according to a scrambled Sobol' sequence.

#### **4.1 Performance Metric**

We measure performance using *simple regret*, also known as *opportunity cost*, which is the expected difference in the value of the solution we would recommend after *n* samples and the best possible value for that problem. As in previous sections, we write  $x^*$  and  $g^*$  for the optimal fixed design and control policy, and  $x^{*n}$  and  $g^{*n}$ for the recommendations after step *n*. The recommendations  $\mathbf{x}^{*n}$  and  $\mathbf{g}^{*n}$  depend on the initial data and the observation noise, and so are random. The simple regret is given by

$$
r^{n} = \mathbb{E}_{\mathbf{u}}[h(\mathbf{x}^{*}, \mathbf{g}^{*}(\mathbf{u}), \mathbf{u})] - \mathbb{E}_{\mathbf{x}^{*n}, \mathbf{g}^{*n}}[\mathbb{E}_{\mathbf{u}}[h(\mathbf{x}^{*n}, \mathbf{g}^{*n}(\mathbf{u}), \mathbf{u}]].
$$
\n(20)

For synthetic functions sampled from a GP, we take expectation over the test problem as well and call the result *expected simple regret*,  $\mathbb{E}_h[\mathbf{r}^n]$ .

We estimate the simple regret by repeating experiments  $M = 100$  times with different random seeds and taking the mean. We use a scrambled Sobol' sample of size  $N_{u,rec} = 128$  for the quasi-Monte Carlo approx-

**Algorithm 4** Bayesian optimization for two-stage stochastic programs using a two-step knowledge gradient

**Input:** Initial sample sizes  $n_1, n_2$  for each step, evaluation budget  $n_{\text{tot},1}, n_{\text{tot},2}$  for each step, discretization sizes  $N_x$  and  $N_y$ , qMC sample sizes  $N_u$  and  $N_{u,rec}$ 

- 1:  $//$  Step one (fix  $x$  and optimize  $g$ )
- 2: Choose  $x_{\text{step-1}} \in \mathbb{X}$
- 3: Evaluate *h* at  $n_1$  points, chosen by combining  $x_{step-1}$  with a scrambled Sobol' sequence on  $\mathbb{Y} \times \mathbb{U}$
- 4: **for**  $n = n_1$  **to**  $n_{\text{tot,1}}$  **do**
- 5: Fit MAP hyperparameters of GP prior, *f*step-1 ∼ GP, on functions Y × U → R as described in Appendix [E.3](#page-38-0)

- $\boldsymbol{y}^n_\text{step-1}, \boldsymbol{u}^{n+1}_\text{step-1} \leftarrow \argmax_{\boldsymbol{y}, \boldsymbol{u}} \alpha^n_\text{2sKG-1}(\boldsymbol{y}, \boldsymbol{u}; \, \mathbb{Y}_\text{disc}, \mathbb{U}_\text{MC})$
- 8: Evaluate  $h(\mathbf{x}_{step-1}, \mathbf{y}_{step-1}^{n+1}, \mathbf{u}_{step-1}^{n+1})$  (expensive)
- 9: **end for**
- 10: Fit MAP hyperparameters of GP prior, *f*step-1 ∼ GP, on functions Y × U → R as described in Appendix [E.3](#page-38-0)
- 11: Let  $g^{*n_{\text{tot},1}} : \mathbb{U} \to \mathbb{Y}$  given by  $g^{*n_{\text{tot},1}}(u) \in \arg \max_{y} \mu^{n_{\text{tot},1}}_{\text{step}-1}(y,u)$
- 12:  $//$  Step two (fix **g** and optimize **x**)
- 13: Evaluate *h* at  $n_2$  points, chosen using scrambled Sobol' sequence on  $\mathbb{X} \times \mathbb{U}$  augmented by *y*-values given by  $g^{*n_{\text{tot},1}}(\cdot)$
- 14: **for**  $n = n_2$  **to**  $n_{\text{tot,2}}$  **do**
- 15: Fit MAP hyperparameters of GP prior,  $f_{\text{step-2}} \sim \mathcal{GP}$ , on functions  $\mathbb{X} \times \mathbb{U} \to \mathbb{R}$  as described in Appendix [E.3](#page-38-0)
- 16: Generate  $\mathbb{X}_{\text{disc}} \leftarrow \text{LHC}(N_x)$ ,  $\mathbb{U}_{\text{MC}} \leftarrow \text{Sobol}(N_u)$
- $\boldsymbol{x}_{\text{step-2}}^{n+1}, \boldsymbol{u}_{\text{step-2}}^{n+1} \leftarrow \arg\max_{\boldsymbol{x},\boldsymbol{u}} \alpha_{\text{2sKG-2}}^{n}(\boldsymbol{x},\boldsymbol{u}; \mathbb{X}_{\text{disc}}, \mathbb{U}_{\text{MC}})$
- 18: Evaluate  $h\left(\mathbf{x}_{\text{step-2}}^{n+1}, \mathbf{g}^{*n_{\text{tot},1}}(\mathbf{u}_{\text{step-2}}^{n+1}), \mathbf{u}_{\text{step-2}}^{n+1}\right)$  (expensive)
- 19: **end for**
- 20: Fit MAP hyperparameters of GP prior,  $f_{\text{step-2}} \sim \mathcal{GP}$ , on functions  $\mathbb{X} \times \mathbb{U} \to \mathbb{R}$  as described in Appendix [E.3](#page-38-0)
- 21: Generate  $\mathbb{U}_{\text{MC,rec}} \leftarrow \text{Sobol}(N_{u,rec})$
- $22$ : Optimize  $\boldsymbol{x}^{*n_{\text{tot},2}} \in \arg \max_{\boldsymbol{x}} \frac{1}{N_{u,\text{rec}}} \sum_{\boldsymbol{u} \in \mathbb{U}_{\text{MC},\text{rec}}} \mu_{\text{step}-2}^{n_{\text{tot},2}}(\boldsymbol{x}, \boldsymbol{u})$

```
Output: x^{*n_{\text{tot},2}}, g^{*n_{\text{tot},1}}
```
imation over **u**. Writing  $x^{*n,i}$ ,  $g^{*n,i}$  for the recommendations in the *i*<sup>th</sup> experiment after *n* data points have been collected, and  $u^1, \ldots, u^{N_{u,\text{rec}}}$  for the qMC sample of **u**, the approximate simple regret is

<span id="page-13-2"></span>
$$
r^n \approx \hat{r}^n = \frac{1}{MN_{u, \text{rec}}} \sum_{i=1}^M \sum_{j=1}^{N_{u, \text{rec}}} \left( h(\boldsymbol{x}^{*n, i}, \boldsymbol{g}^{*n, i}(\boldsymbol{u}^j), \boldsymbol{u}^j) - h(\boldsymbol{x}^*, \boldsymbol{g}^*(\boldsymbol{u}^j), \boldsymbol{u}^j) \right). \tag{21}
$$

For the synthetic functions sampled from a GP, each of the  $M$  experiments is run with a different sample  $h^i$ from the test problem GP.

In the results that follow, we plot this estimate as a function of *n* for each algorithm, along with a 95% confidence interval calculated as two standard errors on either side of the mean.

#### <span id="page-13-0"></span>**4.2 Synthetic examples: random GP samples**

The synthetic examples are generated by sampling a Gaussian process (GP). By using GP samples, we remove model-mismatch problems from the picture, such as landscapes with heterogeneous length scales. For each family of problems, characterized by dimension and length scale, 100 different test problems are generated by taking 100 independent samples of the GP. The samples are generated by randomly sampling the weights and basis vectors for 1024 random Fourier features as in [\(Rahimi & Recht, 2007\)](#page-21-13), using the implementation in BoTorch [\(Balandat et al., 2020\)](#page-18-9).

Figure [2](#page-14-0) shows results for test problems generated from six-dimensional GPs, with different distributions of the dimensions between the variable types. Joint KG and alternating KG perform well in all cases, with the joint version marginally outperforming the alternating one in some places and both significantly outperforming the random and two-step benchmarks.

The two-step KG performs at its best when the higher dimensionality is in the adjustable variable space. This is because it optimizes the adjustable variables first, which is the harder part of the problem. It makes almost no improvements in the first step when the higher dimensionality is in the fixed design space.

We see a similar pattern when examining problems of different length scales. Figure [3](#page-15-0) shows results for test problems generated from three-dimensional GPs – an  $(x, y, u)$ -dimension of  $(1, 1, 1)$  – where one of the variables has a short length scale and the other two have a very long length scale. Again, the joint and alternating KG variants are consistently the best. The two-step algorithms are particularly poor when the short length scale is in the *x*-dimension, since the fixed design is not optimized until the second step.

One motivation for using knowledge gradient is that it naturally handles observation noise. Figure [4](#page-15-1) shows results for GP generated test problems of  $(x, y, u)$ -dimension  $(2, 2, 2)$  with additive Gaussian observation noise. It confirms that the algorithms are not adversely affected by the inclusion of observation noise and that joint and alternating KG continue to significantly outperform the Sobol' and two-step benchmark algorithms.

#### <span id="page-13-1"></span>**4.3 Real world example: design of an optical table**

The optimization landscapes found in real-world problems are typically unlikely to be seen as samples from a stationary GP. To confirm that the joint and alternating KG continue to be the best performers in the presence of model-mismatch, we consider the design of an optical table. This example is a simplification of the example in [\(Salomon, 2019\)](#page-21-4). An optical table is used in optics experiments to reduce the amplitude of vibrations propagated from the environment to the equipment.

We model the table as a rectangle of mass  $m_1 = 200$ kg, supported symmetrically by four springs with spring constant *k* – one at each corner of the table. A damper with adjustable coefficient *c* is located centrally, and the equipment of mass  $m_2 = 20 \text{kg}$  is placed with its center of mass in the center. It is assumed that the equipment is symmetric so that rotational vibration can be neglected. The floor is modeled to vibrate with simple harmonic motion at uncertain frequency  $\omega$ . Figure [5a](#page-16-0) contains a diagram of the set-up.

The system satisfies an ordinary differential equation, and it can be shown (see Appendix [E.2\)](#page-37-0) that the steady-state solution is another simple harmonic motion with the same frequency but a different amplitude

<span id="page-14-0"></span>

Figure 2: Evolution of the expected simple regret for GP sampled problems of different dimensions, with gray shading showing the evaluations attributed to the initial design. Note that the joint and alternating algorithms only use the first initial design phase, while the two-step algorithms use both. Joint KG and alternating KG perform well in all cases, with joint KG approaching zero regret slightly faster than alternating KG. Both algorithms outperform the two-step and random sampling benchmark algorithms. The two-step algorithms do particularly badly when the  $(x, y, u)$ -dimension is  $(4, 1, 1)$  since the first step only optimizes the adjustable variables while the bulk of the optimization problem is in the fixed design space.

<span id="page-15-0"></span>

<span id="page-15-1"></span>Figure 3: Evolution of the expected simple regret for GP sampled problems of different length scales, with gray shading showing the evaluations attributed to the initial design. Note that the joint and alternating algorithms only use the first initial design phase, while the two-step algorithms use both. Joint KG and alternating KG are consistently the best performers, and the two-step algorithms perform particularly poorly when the short length scale is in the *x*-dimension.

Figure 4: Evolution of the expected simple regret for GP sampled problems with additive Gaussian observation noise of standard deviation  $\sigma = 2$ . The problems have  $(x, y, u)$ -dimension (2, 2, 2) and come from the same distribution as those which appear in Figure [2.](#page-14-0) Gray shading shows the evaluations attributed to the initial design. Note that the joint and alternating algorithms only use the first initial design phase, while the two-step algorithms use both. While the performance of all algorithms gets worse with increased levels of observation noise, the joint and alternating KG continue to outperform the Sobol' sequence and two-step benchmarks.

and phase. The objective is to minimize the ratio of the amplitudes of the vibrations of the table and the floor.

For the stochastic optimization problem, the spring constants *k* are taken as the fixed design, the vibration frequency of the floor,  $\omega$ , is the uncertain environmental variable, and the damping coefficient,  $c$ , is the adjustable variable. For the GP modeling, we approximate the negative logarithm of the amplitude ratio,  $-\log_{10}(B/A)$ , in place of the amplitude ratio as a function of *k*, *c* and  $\log_{10}(\omega)$ .

Figure [5b](#page-16-0) shows that joint KG and alternating KG approach zero much faster than the Sobol' and two-step algorithms. The two-step KG is initially the fastest decreasing because, in the first step, it is solving the simpler problem of finding the best damping coefficient, *c*, for a fixed spring constant, *k*. However, because it is not known a priori for how long to run each step, and because a new set of initial samples must be collected each time the algorithm switches steps, it cannot maintain this fast convergence rate.

While this problem is simple enough to have an analytic solution, it is illustrative of more complicated problems which lack symmetry and perfect components and thus where time-consuming physical experiments are to be run in the lab.

<span id="page-16-0"></span>

Figure 5: Schematic diagram and evolution of the simple regret for the optical table experiment. The joint and alternating KG algorithms are the fastest to converge to zero regret.

### **4.4 The cost of optimizing the acquisition function**

It is important that the time required to optimize the acquisition function is negligible compared with the time or cost required to evaluate the expensive objective. As an example, on a (2,2,2)-dimensional test problem, running with 6 CPU cores on an Intel Xeon Platinum 826 2.9GHz processor it took an average of just 21 seconds to optimize the joint KG acquisition function.

Figure [6](#page-17-1) shows the mean wall clock time for a single optimization of the acquisition function for each of the three knowledge gradient variants on the (2,2,2)-dimensional GP test problems. The alternating and two-step KG algorithms each involve two acquisition functions, and the figure shows the average of the time required to optimize each one.

Thanks to the Monte-Carlo approximation of the outer expectation in Equation [\(12\)](#page-7-3), the joint KG algorithm is immediately parallelized when implemented in PyTorch. However, the exact expectation in the alternating (Equation [\(17\)](#page-10-1) and Equation [\(15c\)](#page-9-1)) and two-step KG (Equation [\(19\)](#page-11-0)) require more work to be parallelized, which is beyond the scope of this paper.

Therefore, the timings in Figure [6](#page-17-1) use 6 CPUs for the joint KG, but only 2 CPUs for the alternating and two-step KG since the implementations of the latter mean a larger number of CPUs do not improve the timings.

<span id="page-17-1"></span>Figure 6: Mean wall times required to optimize the acquisition functions on the (2,2,2)-dimensional GP sampled test problems without observation noise. The joint KG is optimized using 6 CPU cores, while the remaining algorithms were given just 2 CPU cores because their implementation means they attain poor cluster utilization on higher numbers of cores.

# **5 Discussion**

The results in Section [4](#page-11-1) show the importance of jointly optimizing the fixed design and control strategy for the adjustable variables. The joint knowledge gradient is conceptually appealing and computationally feasible, while the alternating knowledge gradient provides a natural alternative and demonstrates that the Monte Carlo approximation of the expectation over the hypothesized next observation does not adversely affect the results. It is critically important in Bayesian optimization that optimizing the acquisition function is significantly cheaper than evaluating the expensive objective, *h*. The joint and alternating knowledge gradient algorithms are both applicable to settings where the expensive function takes several minutes or more to evaluate. If further efficiencies were required, then the computational strategy for the joint knowledge gradient would also be naturally suitable for running on a GPU.

There are many possible future research directions. Stochastic programming typically involves explicit constraints, and while the algorithm can support optimizing over constrained spaces X and Y, it would be interesting to extend it to handle black-box constraints as in [\(Ungredda & Branke, 2024\)](#page-22-11). Similarly, the algorithms could be extended to cover standard problems in stochastic programming such as multi-stage decisions and different risk measures such as value-at-risk.

Finally, another limitation of the algorithm is its extensibility to higher dimensions. For example, in the wind farm layout problem, there are typically hundreds of wind turbines leading to hundreds of parameters. High-dimensional Bayesian optimization is an active area of research [\(Binois & Wycoff, 2022\)](#page-18-10) and recent ideas such as local search methods could be incorporated to tackle higher-dimensional two-stage stochastic programs.

# **Appendix**

# <span id="page-22-10"></span>**A Theoretical Results**

In this section, we establish the asymptotic consistency of the value associated with the recommendations of the joint knowledge gradient acquisition function presented in Section [3](#page-5-0) when viewed as an estimator for  $\sup_{x, g} \overline{h}(x, g)$ . This was stated in the main text as Theorem [3.2.](#page-6-2)

**Theorem 3.2.** *Suppose that the objective, h, is a sample from a Gaussian process on*  $\mathbb{X} \times \mathbb{Y} \times \mathbb{U}$ *, and that*  $(X, Y, U$  are compact subsets of  $\mathbb{R}^{d_x}, \mathbb{R}^{d_y}, \mathbb{R}^{d_u}$ , respectively. Assume further that the surrogate  $f \sim \mathcal{GP}(\mu, k)$ *has the same hyperparameters as h so that we may identify*  $f = h$ . Then, viewing the recommendations  $\mathbf{x}^{*n}$ *and* **g** <sup>∗</sup>*<sup>n</sup> as random elements depending on the initial sample, the observation noise, and the function f, we have*

$$
\overline{f}(\mathbf{x}^{*n}, \mathbf{g}^{*n}) \to \sup_{\substack{\mathbf{x} \in \mathbb{X} \\ \mathbf{g} : \mathbb{U} \to \mathbb{Y}}} \overline{f}(\mathbf{x}, \mathbf{g}) \qquad as \qquad n \to \infty
$$

*almost surely and in mean.*

As noted in Section [3.1,](#page-6-3) rather than proving consistency for a specific objective function *h*, we instead prove it almost surely and in mean when *h* is a draw from a Gaussian process with the same distribution as the surrogate model  $f$ . Therefore, to simplify notation, we identify  $h = f$ .

We also assume that the hyperparameters of the distribution of *f* remain fixed throughout the optimization, and are not refitted every iteration as described in Algorithm [1](#page-5-1) and Algorithm [2.](#page-8-0) This is the standard assumption in existing proofs of the asymptotic consistency of knowledge gradient acquisition functions [\(Bect et al., 2019;](#page-18-8) [Toscano-Palmerin & Frazier, 2022;](#page-22-5) [Buckingham et al., 2023\)](#page-18-6). However, it is important to note that it is likely that the equivalent theorem does not hold when the hyperparameters are fitted after each new observation. Indeed, [Bull](#page-18-11) [\(2011\)](#page-18-11) show that for standard GP priors with parameters sequentially reestimated from the data, there exist smooth objectives *f* on which Bayesian Optimization using the expected improvement acquisition function does not converge. Therefore, for the case of hyperparameters estimated from the data, we rely on experimental evidence that this does not happen in practice.

The proof of consistency is based on the work by [\(Bect et al., 2019\)](#page-18-8) and [\(Buckingham et al., 2023\)](#page-18-6), but avoids the use of random measures which is found in [\(Bect et al., 2019\)](#page-18-8). It begins by showing that the joint knowledge gradient converges almost surely, uniformly to zero in Theorem [A.10.](#page-27-0) Further, the posterior mean and covariance of  $\bar{f}$  are shown to converge uniformly to continuous limits in Proposition [A.12](#page-28-0) by observing that the posterior mean and covariance of *f* are martingales in Banach spaces. These two facts are combined to show in Proposition [A.16](#page-31-0) that the uniform limit,  $\overline{\mu}^{\infty}$ , of the posterior means of  $\overline{f}$  has sample paths which are almost surely equal to the sample paths of  $\overline{f}$  (up to a constant). Whence, convergence of the values of the recommendations can be established in Theorem [A.17.](#page-32-0)

#### **A.1 Notation, statistical model and assumptions**

We assume that the spaces  $\mathbb{X} \subset \mathbb{R}^{d_x}$ ,  $\mathbb{Y} \subset \mathbb{R}^{d_y}$  and  $\mathbb{U} \subset \mathbb{R}^{d_u}$  are compact and that the objective  $f \sim \mathcal{GP}(\mu, k)$ is a Gaussian process with index set  $\tilde{X} = X \times Y \times U$  defined on a probability space  $(\Omega, \mathcal{F}, \mathbb{P})$ . We further assume that the prior mean function,  $\mu$ , and covariance function,  $k$ , are continuous, and that there exists a version of *f* with continuous sample paths. A sufficient condition for this is that the mean function  $\mu$  is continuous and that the kernel satisfies [\(Adler & Taylor, 2009,](#page-17-2) Theorem 1.4.1)

$$
\exists 0 < c < \infty \text{ and } \exists \beta, \delta > 0 \text{ such that } \forall \tilde{x}, \tilde{x}' \in \tilde{\mathbb{X}} \text{ with } \|\tilde{x} - \tilde{x}'\|_2 < \delta,
$$
\n
$$
\mathbb{E}[|f(\tilde{x}) - f(\tilde{x}')|^2] = k(\tilde{x}, \tilde{x}) + k(\tilde{x}', \tilde{x}') - 2k(\tilde{x}, \tilde{x}') \le \frac{c}{\left|\log\left\|\tilde{x} - \tilde{x}'\right\|_2\right|^{1+\beta}}.\tag{22}
$$

As in the main text, let  $\tilde{\mathbf{x}}^1, \tilde{\mathbf{x}}^2, \dots \in \tilde{\mathbb{X}}$  denote the (data dependent) design points with  $\tilde{\mathbf{x}}^n = (\mathbf{x}^n, \mathbf{y}^n, \mathbf{u}^n)$ for each *n*. The first  $n_0$  of these are selected according to a (possibly random) initial design such as a Latin Hypercube or scrambled Sobol' sequence, and the remainder are selected sequentially based on the observations made up to that point. Let  $v^1, v^2, \dots \in \mathbb{R}$  be the corresponding (noisy) observations given by

$$
\forall n = 1, 2, \dots \qquad \mathbf{v}^n = f(\mathbf{x}^n, \mathbf{y}^n, \mathbf{u}^n) + \varepsilon^n \qquad \text{where} \qquad \forall n \quad \varepsilon^n \sim \mathcal{N}(0, \sigma^2) \text{ i.i.d.}
$$
 (23)

where the  $\varepsilon^1, \varepsilon^2, \ldots$  are also independent of f. This is Equation [\(1\)](#page-2-1) from the main text, restated here for convenience. Note that now we view the design points  $\tilde{\mathbf{x}}^1, \tilde{\mathbf{x}}^2$  as random vectors, since they depend on the random initial design and on the observation noise. For each *n*, let  $\mathcal{F}^n = \sigma(\tilde{\mathbf{x}}^1, \mathbf{v}^1, \dots, \tilde{\mathbf{x}}^n, \mathbf{v}^n)$  be the

sigma-algebra generated by the first *n* design points and observations, so that  $(\mathcal{F}^n)_{n=0}^{\infty}$  forms a filtration of  $\mathcal{F}$ .

Our objective is not *f* but the expectation of *f* over the environmental variables **u**,

$$
\overline{f}(\mathbf{x}, \mathbf{g}) = \mathbb{E}_{\mathbf{u}}[f(\mathbf{x}, \mathbf{g}(\mathbf{u}), \mathbf{u})]. \tag{24}
$$

Note here that **u** and *f* are independent and so formally this is the expectation of  $f(x, g(u), u)$  conditional on the GP *f*.

It will be useful later when talking about the posterior mean of  $\overline{f}$  to be able to freely interchange the order of integration over *f* and **u**. This is possible by Fubini's Theorem / the law of total expectation, provided that the expectation  $\mathbb{E}[f(\mathbf{x}, \mathbf{g}(\mathbf{u}), \mathbf{u})]$  over both jointly is well defined.

**Lemma A.1.** *We can exchange the order of integration over f and* **u** *when calculating the posterior mean of f. That is,*

$$
\overline{\mu}^n(\boldsymbol{x},\boldsymbol{g}) = \mathbb{E}\big[\overline{f}(\boldsymbol{x},\boldsymbol{g})\big|\,\mathcal{F}^n\big] = \mathbb{E}_{\mathbf{u}}\big[\mu^n(\boldsymbol{x},\boldsymbol{g}(\mathbf{u}),\mathbf{u})\big].
$$

*Proof.* As observed, in order to apply Fubini's theorem, it is sufficient to check that  $\mathbb{E}[(f(\mathbf{x}, g(\mathbf{u}), \mathbf{u}))_+] < \infty$ and  $\mathbb{E}[(f(\mathbf{x}, g(\mathbf{u}), \mathbf{u}))_{-}] < \infty$ , where  $(\cdot)_{+}$  and  $(\cdot)_{-}$  denote the positive and negative parts of the random variable, and the expectation is taken jointly over both *f* and **u**. This follows immediately from [\(Azaïs &](#page-18-12) [Wschebor, 2009,](#page-18-12) Theorem 2.9). Indeed, write  $f = \mu + f_0$  with  $f_0$  a zero mean GP and  $\mu$  deterministic. Then  $f_0$  has almost surely continuous sample paths and  $\tilde{X}$  is compact, so  $\sup_{\tilde{x}} f_0(\tilde{x}) < \infty$  almost surely, and so the theorem gives  $\mathbb{E}|\sup_{\tilde{x}} f_0(\tilde{x})| < \infty$ . Since  $f_0$  and  $-f_0$  have the same distribution, we also have  $\mathbb{E}|\inf_{\tilde{\boldsymbol{x}}}f_0(\tilde{\boldsymbol{x}})| < \infty$  and therefore

$$
\mathbb{E}[(f(\boldsymbol{x},\boldsymbol{g}(\mathbf{u}),\mathbf{u}))_+] \leq \mathbb{E}\left[\left|\sup_{\tilde{\boldsymbol{x}}}f(\tilde{\boldsymbol{x}})\right|\right] \leq \left|\sup_{\tilde{\boldsymbol{x}}} \mu(\tilde{\boldsymbol{x}})\right| + \mathbb{E}\left[\left|\sup_{\tilde{\boldsymbol{x}}} f_0(\tilde{\boldsymbol{x}})\right|\right] < \infty, \n\mathbb{E}[(f(\boldsymbol{x},\boldsymbol{g}(\mathbf{u}),\mathbf{u}))_-] \leq \mathbb{E}\left[\left|\inf_{\tilde{\boldsymbol{x}}}f(\tilde{\boldsymbol{x}})\right|\right] \leq \left|\inf_{\tilde{\boldsymbol{x}}} \mu(\tilde{\boldsymbol{x}})\right| + \mathbb{E}\left[\left|\inf_{\tilde{\boldsymbol{x}}} f_0(\tilde{\boldsymbol{x}})\right|\right] < \infty,
$$

as required.

The sample paths of  $f$  are continuous and  $\tilde{\mathbb{X}}$  is compact, so  $f$  is bounded and attains its bounds almost surely. It turns out that the objective  $\overline{f}$  also attains its bounds, so our optimization problem is well-posed.

<span id="page-24-0"></span>**Lemma A.2.** *The objective*  $\overline{f}$  *is bounded and attains its bounds almost surely. Furthermore, there exists a choice*  $\mathbf{x} \in \mathbb{X}, \mathbf{g} : \mathbb{U} \to \mathbb{Y}$  *maximizing (resp. minimizing)*  $\overline{f}$  *such that* **g** *has Borel-measurable sample paths.* 

*Proof.* We prove the result for the upper bound, but the equivalent for the lower bound is analogous.

The sample paths of  $f$  are continuous and  $X$  is compact, so they are uniformly continuous. Therefore, the sample paths of the map  $(x, u) \mapsto \max_{y} f(x, y, u)$  are also uniformly continuous. Hence, the map  $x \mapsto \int \max_{\mathbf{y}} f(\mathbf{x}, \mathbf{y}, \mathbf{u}) \mathbb{P}(\mathrm{d}\mathbf{u})$  also has (uniformly) continuous sample paths. Therefore, since X is compact, this map is bounded and attains its bounds, so let

$$
\mathbf{x}^* \in \arg\max_{\mathbf{x} \in \mathbb{X}} \mathbb{E}_{\mathbf{u}} \Big[\max_{\mathbf{y}} f(\mathbf{x}, \mathbf{y}, \mathbf{u})\Big].
$$

Now, for each  $u \in U$ , the map  $y \mapsto f(x^*, y, u)$  has continuous sample paths, and Y is compact, so it is bounded and attains its bounds. Therefore, we can define a map  $\mathbf{g}^* : \mathbb{U} \to \mathbb{Y}$  by

$$
\mathbf{g}^*(\boldsymbol{u}) \in \argmax_{\mathbf{y} \in \mathbb{Y}} f(\mathbf{x}^*, \mathbf{y}, \boldsymbol{u}).
$$

By construction, the pair  $\mathbf{x}^*, \mathbf{g}^*$  are an upper bound for  $\overline{f}$ .

It remains to be shown that  $g^*$  can be chosen to have measurable sample paths with respect to the Borel sigma-algebras on U and Y. This is the content of Proposition 7.33 in [\(Bertsekas & Shreve, 1996\)](#page-18-13).  $\Box$ 

In order to argue rigorously about the knowledge gradient, we must make the formula in Equation [\(9\)](#page-6-1) concrete. Let  $\mathbf{v}_{\tilde{\mathbf{x}}} = \tilde{f}(\tilde{\mathbf{x}}) + \varepsilon$  with  $\varepsilon \sim \mathcal{N}(0, \sigma^2)$  represent a possible noisy observation at  $\tilde{\mathbf{x}} \in \tilde{\mathbb{X}}$ . For each n, let  $\overline{\mu}^{n+1}(\mathbf{x}', \mathbf{g}'; \tilde{\mathbf{x}}, \mathbf{v}_{\tilde{x}}) = \mathbb{E}[\overline{f}(\mathbf{x}', \mathbf{g}') | \mathcal{F}^n, \mathbf{v}_{\tilde{\mathbf{x}}}]$  be the expectation of  $\overline{f}$  conditional on the *n* observations so far, and the proposed new observation  $v_{\tilde{x}}$  taken at  $\tilde{x}$ . Note that  $\overline{\mu}^{n+1}(x',g') = \overline{\mu}^{n+1}(x',g';\tilde{x}^{n+1},v^{n+1}),$  so this is consistent with our notation from the main text. With this notation, Equation [\(9\)](#page-6-1) becomes

<span id="page-25-1"></span>
$$
\alpha_{jKG}^n(\tilde{\boldsymbol{x}}) = \mathbb{E}\left[\max_{\substack{\mathbf{x}' \in \mathbb{X} \\ \mathbf{g}': \mathbb{U} \to \mathbb{Y}}} \overline{\mu}^{n+1}(\mathbf{x}', \mathbf{g}'; \tilde{\boldsymbol{x}}, \mathbf{v}_{\tilde{\boldsymbol{x}}}) \middle| \mathcal{F}^n\right] - \max_{\substack{\mathbf{x}' \in \mathbb{X} \\ \mathbf{g}': \mathbb{U} \to \mathbb{Y}}} \overline{\mu}^n(\mathbf{x}', \mathbf{g}'). \tag{25}
$$

We are justified in using a maximum instead of a supremum here because the posterior means  $\bar{\mu}^n$  are all bounded and attain their bounds.

<span id="page-25-3"></span>**Lemma A.3.** For all *n*, the posterior mean  $\bar{\mu}^n$  is bounded and attains its bounds. Furthermore, there exists *a choice*  $\mathbf{x}^{*n} \in \mathbb{X}$  *and*  $\mathbf{g}^{*n} : \mathbb{U} \to \mathbb{Y}$  *maximizing (resp. minimizing)*  $\overline{\mu}^{\infty}$  *such that*  $\mathbf{g}^{*n}$  *has Borel-measurable sample paths.*

*Proof.* Let  $n \in \mathbb{N}_0$ . Then  $\mu^n$  is a stochastic process with continuous sample paths and the result follows by the same argument as Lemma [A.2.](#page-24-0) П

This result also means that our recommendations  $\mathbf{x}^{*n}, \mathbf{g}^{*n} \in \arg \max_{\mathbf{x}, \mathbf{g}} \bar{\mu}^n(\mathbf{x}, \mathbf{g})$  from Equation [\(8\)](#page-5-4) in the main text are well defined.

So far, we have not specified the mechanism by which the design points  $\tilde{\mathbf{x}}^1, \tilde{\mathbf{x}}^2, \ldots$  are chosen. Intuitively, we wish to choose them to maximize the joint knowledge gradient in Equation [\(25\)](#page-25-1). However, in the case  $\sigma = 0$  of noiseless observations, the knowledge gradient is not continuous at the observations and, therefore, it is not obvious that it attains its supremum (even though  $X$  is compact). Furthermore, in practice, we can only hope to maximize the knowledge gradient approximately. To that end, we assume that for each  $n \geq n_0$ , we optimize  $\alpha_{jKG}^n$  to within some small  $\eta^n$  of the optimum,

<span id="page-25-2"></span>
$$
\alpha_{jKG}^n(\tilde{\mathbf{x}}^{n+1}) > \sup_{\tilde{\mathbf{x}}' \in \tilde{\mathbf{x}}} \alpha_{jKG}^n(\tilde{\mathbf{x}}') - \eta^n,\tag{26}
$$

where  $(\eta^n)_{n=n_0}^{\infty}$  is a positive sequence with  $\eta^n \to 0$  as  $n \to \infty$ . Further, we assume that each  $\tilde{\mathbf{x}}^{n+1}$  is  $\mathcal{F}^n$ -measurable. That is, that the optimization is deterministic given the first *n* observations.

We conclude this section with a short proof that the joint knowledge gradient is non-negative. This was stated as Lemma [3.1](#page-6-0) in the main text.

<span id="page-25-0"></span>**Proposition A.4** (Lemma [3.1](#page-6-0) from the main text)**.** *The joint knowledge gradient is almost surely nonnegative,*

$$
\forall n \in \mathbb{N}_0 \ \forall \, \tilde{\boldsymbol{x}} \in \tilde{\mathbb{X}} \quad \alpha_{jKG}^n(\tilde{\boldsymbol{x}}) \ge 0 \qquad a.s.
$$

*Proof.* Let  $\tilde{x} \in \tilde{\mathbb{X}}$  and  $n \in \mathbb{N}_0$ . Then, for all  $x'' \in \mathbb{X}$  and  $g'' : \mathbb{U} \to \mathbb{Y}$ ,

$$
\max_{\mathbf{x}',\mathbf{g}'} \mathbb{E}\big[\overline{f}(\mathbf{x}',\mathbf{g}')\,\big|\,\mathcal{F}^n,v_{\tilde{\mathbf{x}}}\big] \geq \mathbb{E}\big[\overline{f}(\mathbf{x}'',\mathbf{g}'')\,\big|\,\mathcal{F}^n,v_{\tilde{\mathbf{x}}}\big].
$$

Taking expectation conditional on  $\mathcal{F}^n$  gives

$$
\mathbb{E}\bigg[\max_{\mathbf{x}',\mathbf{g}'}\mathbb{E}\big[\overline{f}(\mathbf{x}',\mathbf{g}'\,\big|\,\mathcal{F}^n,\mathrm{v}_{\tilde{\bm{x}}})\big]\bigg|\,\mathcal{F}^n\bigg]\geq \mathbb{E}\big[\overline{f}(\mathbf{x}'',\mathbf{g}'')\,\big|\,\mathcal{F}^n\big]=\overline{\mu}^n(\mathbf{x}'',\mathbf{g}'').
$$

Whence, this holds for the maximum over  $x''$  and  $g''$ ,

$$
\mathbb{E}\left[\max_{\mathbf{x}',\mathbf{g}'}\mathbb{E}\left[\overline{f}(\mathbf{x}',\mathbf{g}')\,\big|\,\mathcal{F}^n,\mathbf{v}_{\tilde{\mathbf{x}}}\right]\,\bigg|\,\mathcal{F}^n\right]\geq \max_{\mathbf{x}'',\mathbf{g}''}\overline{\mu}^n(\mathbf{x}'',\mathbf{g}'')
$$
\n
$$
\Rightarrow \qquad \alpha_{jKG}^n(\tilde{\mathbf{x}}) = \mathbb{E}\left[\max_{\mathbf{x}',\mathbf{g}'}\mathbb{E}\left[\overline{f}(\mathbf{x}',\mathbf{g}')\,\big|\,\mathcal{F}^n,\mathbf{v}_{\tilde{\mathbf{x}}}\right]\,\bigg|\,\mathcal{F}^n\right] - \max_{\mathbf{x}'',\mathbf{g}''}\overline{\mu}^n(\mathbf{x}'',\mathbf{g}'') \geq 0.
$$

# $\mathsf{A.2}$  Convergence of  $\alpha^n_{\mathsf{jKG}}$  to zero

In this section we will prove that almost surely, as we collect more data, the joint knowledge gradient converges uniformly to zero. This is the first step in proving that the recommendations converge to optimal. In the field of sequential uncertainty reduction [\(Bect et al., 2019\)](#page-18-8), the concept of residual uncertainty is central.

<span id="page-26-0"></span>**Definition A.5.** For  $n \in \mathbb{N}_0$ , the *residual uncertainty* associated with the joint knowledge gradient is the expected difference between the maximum of the conditional expectation of  $\overline{f}$  and the maximum of  $\overline{f}$  itself,

<span id="page-26-1"></span>
$$
H^{n} = \mathbb{E}\left[\max_{\substack{\mathbf{x}' \in \mathbb{X} \\ \mathbf{g}': \mathbb{U} \to \mathbb{Y}}} \overline{f}(\mathbf{x}', \mathbf{g}')\middle| \mathcal{F}^{n}\right] - \max_{\substack{\mathbf{x}' \in \mathbb{X} \\ \mathbf{g}': \mathbb{U} \to \mathbb{Y}}} \underbrace{\mathbb{E}\left[\overline{f}(\mathbf{x}', \mathbf{g}')\middle| \mathcal{F}^{n}\right]}_{\overline{\mu}^{n}(\mathbf{x}', \mathbf{g}')}.
$$
(27)

It measures how well the maximum of the posterior mean  $\bar{\mu}^n$  approximates the maximum of  $\bar{f}$ .

<span id="page-26-2"></span>*Remark* A.6. For each  $n \geq 0$ , the joint knowledge gradient at  $\tilde{\mathbf{x}}^{n+1}$  is the expected reduction in residual uncertainty,

$$
\alpha_{jKG}^n(\tilde{\mathbf{x}}^{n+1}) = H^n - \mathbb{E}[H^{n+1} | \mathcal{F}^n].
$$
\n(28)

Indeed, the first term,  $\mathbb{E}[\max_{\mathbf{x}',\mathbf{g}'}\overline{f}(\mathbf{x}',\mathbf{g}')|\mathcal{F}^n]$ , cancels and we have

$$
H^{n}-\mathbb{E}[H^{n+1} | \mathcal{F}^{n}]=\mathbb{E}\bigg[\max_{\mathbf{x}',\mathbf{g}'}\overline{\mu}^{n+1}(\mathbf{x}',\mathbf{g}')\bigg|\mathcal{F}^{n}\bigg]-\max_{\mathbf{x}',\mathbf{g}'}\overline{\mu}^{n}(\mathbf{x}',\mathbf{g}')=\alpha_{jKG}^{n}(\tilde{\mathbf{x}}^{n+1}).
$$

The last equality here uses the fact that  $\tilde{\mathbf{x}}^{n+1}$  is  $\mathcal{F}^n$ -measurable.

<span id="page-26-3"></span>**Lemma A.7.** *The residual uncertainty in Definition [A.5](#page-26-0) is well defined and non-negative. That is, for all*  $n, 0 \leq H^n < \infty$  *almost surely.* 

*Proof.* Let  $n \in \mathbb{N}_0$ . We will first show that  $|H^n| < \infty$  almost surely. We will bound each term separately by the expected maximum of the absolute value of f, then show that this is finite. Recalling that  $\bar{f}(\bm{x}', \bm{g}') =$  $\mathbb{E}_{\mathbf{u}'}[f(\mathbf{x}', \mathbf{y}', \mathbf{u}')]$ , we have for the first term in Equation [\(27\)](#page-26-1),

$$
\left| \mathbb{E} \Big[ \max_{\mathbf{x}', \mathbf{g}'} \overline{f}(\mathbf{x}', \mathbf{g}') \Big| \mathcal{F}^n \Big] \right| \leq \mathbb{E} \Big[ \max_{\mathbf{x}', \mathbf{g}'} \left| \overline{f}(\mathbf{x}', \mathbf{g}') \right| \Big| \mathcal{F}^n \Big] \leq \mathbb{E} \Big[ \max_{\mathbf{x}', \mathbf{g}'} \mathbb{E}_{\mathbf{u}'} \big[ |f(\mathbf{x}', \mathbf{g}'(\mathbf{u}'), \mathbf{u}')| \big] \Big| \mathcal{F}^n \Big] \leq \mathbb{E} \Big[ \max_{\mathbf{x}', \mathbf{y}', \mathbf{u}'} |f(\mathbf{x}', \mathbf{y}', \mathbf{u}')| \Big| \mathcal{F}^n \Big].
$$

Similarly, for the second term,

$$
\left| \max_{\mathbf{x}',\mathbf{g}'} \mathbb{E} \left[ \overline{f}(\mathbf{x}',\mathbf{g}') \, \middle| \, \mathcal{F}^n \right] \right| \leq \max_{\mathbf{x}',\mathbf{g}'} \mathbb{E} \left[ \left| \overline{f}(\mathbf{x}',\mathbf{g}') \right| \, \middle| \, \mathcal{F}^n \right] \\
\leq \max_{\mathbf{x}',\mathbf{g}'} \mathbb{E} \left[ \mathbb{E}_{\mathbf{u}'} \left[ \left| f(\mathbf{x}',\mathbf{g}'(\mathbf{u}'),\mathbf{u}') \right| \right] \, \middle| \, \mathcal{F}^n \right] \\
\leq \max_{\mathbf{x}',\mathbf{y}'} \mathbb{E} \left[ \max_{\mathbf{u}'} \left| f(\mathbf{x}',\mathbf{y}',\mathbf{u}') \right| \, \middle| \, \mathcal{F}^n \right] \\
\leq \mathbb{E} \left[ \max_{\mathbf{x}',\mathbf{y}',\mathbf{u}'} \left| f(\mathbf{x}',\mathbf{y}',\mathbf{u}') \right| \, \middle| \, \mathcal{F}^n \right].
$$

Thus,

$$
|H^n| \leq \left| \mathbb{E}\left[\max_{\mathbf{x}',\mathbf{g}'} \overline{f}(\mathbf{x}',\mathbf{g}')\,\bigg|\,\mathcal{F}^n\right] \right| + \left|\max_{\mathbf{x}',\mathbf{g}'} \mathbb{E}[\overline{f}(\mathbf{x}',\mathbf{g}')\,|\,\mathcal{F}^n]\right| \leq 2 \, \mathbb{E}\left[\max_{\mathbf{x}',\mathbf{y}',\mathbf{u}'}|f(\mathbf{x}',\mathbf{y}',\mathbf{u}')|\,\bigg|\,\mathcal{F}^n\right].
$$

This upper bound is non-negative, so it suffices to show that its expectation is finite. That is, we wish to show

$$
\mathbb{E}\bigg[\max_{\mathbf{x}',\mathbf{y}',\mathbf{u}'}|f(\mathbf{x}',\mathbf{y}',\mathbf{u}')|\bigg] < \infty.
$$

This follows from Lemma [A.9](#page-27-1) which follows this proof (setting  $p = 1$ ).

It remains to show that  $H^n > 0$  almost surely. This follows because the expectation of the maximum must be at least the maximum of the expectation, by a very similar argument to Proposition [A.4.](#page-25-0) П

*Remark* A.8. It is possible to show that  $(H^n)_{n=0}^{\infty}$  form a non-negative supermartingale with respect to  $\mathcal{F}^n$ , and this is the route taken in [\(Bect et al., 2019\)](#page-18-8). However, we will be able to get by with Proposition [A.4](#page-25-0) and Remark [A.6.](#page-26-2)

<span id="page-27-1"></span>**Lemma A.9.** *For any*  $1 \leq p < \infty$ *,* 

$$
\mathbb{E}\bigg[\bigg(\sup_{\tilde{\boldsymbol{x}}\in\tilde{\mathbb{X}}} |f(\tilde{\boldsymbol{x}})|\bigg)^p\bigg] < \infty.
$$

*Proof.* Let  $1 \leq p < \infty$ . By Jensen's inequality,

$$
\left(\sup_{\tilde{\boldsymbol{x}}'\in\tilde{\mathbb{X}}} |f(\tilde{\boldsymbol{x}}')|\right)^p=\left(\max\left\{\sup_{\tilde{\boldsymbol{x}}'\in\tilde{\mathbb{X}}}f(\tilde{\boldsymbol{x}}'),\sup_{\tilde{\boldsymbol{x}}'\in\tilde{\mathbb{X}}} -f(\tilde{\boldsymbol{x}}')\right\}\right)^p\leq \left|\sup_{\tilde{\boldsymbol{x}}'}f(\tilde{\boldsymbol{x}}')\right|^p+\left|\sup_{\tilde{\boldsymbol{x}}'} -f(\tilde{\boldsymbol{x}}')\right|^p.
$$

Assume first that *f* has mean zero. Then *f* and −*f* are identically distributed, and

$$
\mathbb{E}\left[\left(\sup_{\tilde{\boldsymbol{x}}'\in\tilde{\mathbb{X}}} |f(\tilde{\boldsymbol{x}}')|\right)^p\right] \leq 2 \mathbb{E}\left[\left|\sup_{\tilde{\boldsymbol{x}}'} f(\tilde{\boldsymbol{x}}')\right|^p\right].
$$

This upper bound is finite, by [\(Azaïs & Wschebor, 2009,](#page-18-12) Equation 2.34).

In the case where *f* does not have mean zero, write  $f(\tilde{x}) = \mu(\tilde{x}) + f_0(\tilde{x})$  where  $f_0$  is a zero mean GP and  $\mu$  is deterministic. Then  $\sup_{\tilde{\mathbf{x}}'} |f(\tilde{\mathbf{x}}')| \leq \sup_{\tilde{\mathbf{x}}'} |\mu(\tilde{\mathbf{x}}')| + \sup_{\tilde{\mathbf{x}}'} |f_0(\tilde{\mathbf{x}}')|$  and so the integer moments of  $\sup_{\tilde{\mathbf{x}}'} |f(\tilde{\mathbf{x}}')|$ are bounded above by a linear combination of the integer moments of  $\sup_{\tilde{x}'} |f_0(\tilde{x}')|$  of degree at most p,  $\Box$ which are finite. For non-integer p, the result follows by rounding up to the next largest integer.

<span id="page-27-0"></span>**Theorem A.10.** *The joint knowledge gradient converges almost surely, uniformly to zero. That is,*

$$
\mathbb{P}\bigg(\sup_{\tilde{\mathbf{x}} \in \tilde{\mathbb{X}}} \alpha_{jKG}^n(\tilde{\mathbf{x}}) \to 0 \quad as \quad n \to 0\bigg) = 1.
$$

*Proof.* For each integer  $n \geq 0$ , let  $\Delta^{n+1} = H^n - H^{n+1}$  and  $\overline{\Delta}^{n+1} = \mathbb{E}[\Delta^{n+1} | \mathcal{F}^n]$ . Therefore,

$$
\overline{\Delta}^{n+1} = \alpha_{jKG}^{n}(\tilde{\mathbf{x}}^{n+1}) \ge 0
$$

by Remark [A.6](#page-26-2) and Proposition [A.4.](#page-25-0) Observe that the telescopic sum  $\sum_{j=1}^{n} \Delta^{j} = H^{0} - H^{n}$ . Therefore,

$$
\mathbb{E}\biggl[\sum_{j=1}^n \overline{\Delta}^j\biggr] = \mathbb{E}\biggl[\sum_{j=1}^n \Delta^j\biggr] = \mathbb{E}[H^0 - H^n] \leq \mathbb{E}[H^0] < \infty
$$

by Lemma [A.7.](#page-26-3) Hence, since  $\overline{\Delta}^n$  is almost surely non-negative for all *n*, we have  $\mathbb{E}[\sum_{n=1}^{\infty} \overline{\Delta}^n] < \infty$  by the monotone convergence theorem. Whence,  $\overline{\Delta}^n \to 0$  as  $n \to \infty$  almost surely.

We chose our design points to maximize the knowledge gradient as in Equation [\(26\)](#page-25-2). Therefore, for all  $n \geq n_0$ ,

$$
0 \le \sup_{\tilde{\mathbf{x}} \in \tilde{\mathbb{X}}} \alpha_{jKG}^n(\tilde{\mathbf{x}}) < \alpha_{jKG}^n(\tilde{\mathbf{x}}^{n+1}) + \eta^n = \overline{\Delta}^{n+1} + \eta^n \to 0 \quad \text{as} \quad n \to \infty \quad \text{a.s.}
$$

which establishes the result.

#### **A.3 Uniform convergence of the posterior mean and covariance functions**

In this section, we establish the uniform convergence of the posterior mean and covariance functions of *f* and *f*. This will be an important ingredient in proving convergence of the values of the recommendations.

Let  $\mathcal{F}^{\infty} = \sigma(\cup_{n=0}^{\infty} \mathcal{F}^n)$  be the sigma-algebra generated by the  $\mathcal{F}^n$ . Define processes

$$
\mu^{\infty} : \tilde{\mathbb{X}} \to \mathbb{R} \qquad \qquad \tilde{x} \mapsto \mathbb{E}[f(\tilde{x}) \, | \, \mathcal{F}^{\infty}], \tag{29a}
$$

$$
k^{\infty} : \tilde{\mathbb{X}} \times \tilde{\mathbb{X}} \to \mathbb{R} \qquad (\tilde{x}, \tilde{x}') \mapsto \text{Cov}[f(\tilde{x}), f(\tilde{x}') \, | \, \mathcal{F}^{\infty}]. \tag{29b}
$$

The proof uses the theory of martingales in Banach spaces. The Gaussian process, *f*, is defined on the probability space  $(\Omega, \mathcal{F}, \mathbb{P})$  and can be viewed as a function  $f : \Omega \times \mathbb{X} \to \mathbb{R}$ ,  $(\omega, \tilde{x}) \mapsto f(\tilde{x})(\omega)$ . The sigma-algebra  $\mathcal F$  contains all the events generated by the finite dimensional distributions of  $f$  and, since sigma-algebras are closed under countable intersections,  $F$  also contains all events which can be described by the value of  $f$  at countably many locations in  $\tilde{X}$ . We are considering the version of  $f$  with continuous sample paths and  $\tilde{\mathbf{X}}$  is separable, and so  $\mathcal F$  contains all events described by the sample paths of  $f$ . That is, we can view *f* as a measurable function  $f: \Omega \to C(\mathbb{X}), \omega \mapsto (\tilde{x} \mapsto f(\omega, \tilde{x}))$  taking values in the space  $C(\mathbb{X})$  of continuous, real-valued functions on X. In other words, *f* is a random element in  $\mathcal{C}(\mathbb{X})$ , defined on  $(\Omega, \mathcal{F}, \mathbb{P})$ .

Since  $\tilde{\mathbb{X}}$  is compact, the space  $\mathcal{C}(\tilde{\mathbb{X}})$  of continuous functions  $\tilde{\mathbb{X}} \to \mathbb{R}$  forms a Banach space when equipped with the supremum norm,  $\|\cdot\|_{\infty}$ . For  $1 \leq p < \infty$ , we denote by  $L_p(\Omega, \mathcal{F}, \mathbb{P}; \mathcal{C}(\mathbb{X}))$ , the space of (Bochner-) measurable functions, f, with  $\int ||f||^p_{\infty} d\mathbb{P} = \mathbb{E}[||f||^p_{\infty}] < \infty$ . Note that, since  $\mathcal{C}(\mathbb{X})$  is separable, the notion of Bochner-measurability coincides with that of Borel-measurability, by Pettis' theorem [\(van Neerven, 2022,](#page-22-12) Theorem 1.47).

<span id="page-28-1"></span>**Proposition A.11.** For any choice of design points  $\tilde{\mathbf{x}}^1, \tilde{\mathbf{x}}^2, \ldots$ , the sequences of stochastic processes  $\mu^n \to$  $\mu^{\infty}$  and  $k^n \to k^{\infty}$  converge uniformly as  $n \to \infty$ , both almost surely and in  $L^p$  for all  $1 \leq p < \infty$ . *Furthermore, the limits*  $\mu^{\infty}$  *and*  $k^{\infty}$  *are continuous.* 

*Proof.* For any  $1 \leq p < \infty$ ,  $\mathbb{E}[\|f\|_{\infty}^p] < \infty$  by Lemma [A.9](#page-27-1) and so  $f \in L_p(\Omega, \mathcal{F}, \mathbb{P}; C(\tilde{\mathbb{X}}))$ . The conditional means  $\mu^n$  and  $\mu^\infty$  have continuous sample paths since  $L_p(\Omega, \mathcal{F}, \mathbb{P}; \mathcal{C}(\tilde{\mathbb{X}}))$  is closed under conditional expec-tation [\(Pisier, 2016,](#page-21-14) Proposition 1.10), and so  $(\mu^n)_{n=0}^{\infty}$  is a martingale in  $\mathcal{C}(\tilde{\mathbb{X}})$ . Therefore,  $\mu^n \to \mu^{\infty}$  in  $L^p(\Omega, \mathcal{F}, \mathbb{P}; \mathcal{C}(\tilde{\mathbb{X}}))$  and almost surely by Theorems 1.14 and 1.30 in [\(Pisier, 2016\)](#page-21-14), respectively. Since this space uses the supremum norm, this corresponds to uniform convergence of the processes.

We can use the same argument to show convergence of the second moments,  $\mu_{(2)}^n(\tilde{x}, \tilde{x}') = \mathbb{E}[f(\tilde{x})f(\tilde{x}') | \mathcal{F}^n]$ in the Banach space of continuous, real-valued functions  $\mathcal{C}(\tilde{\mathbb{X}} \times \tilde{\mathbb{X}})$ . The process  $f_{(2)}(\tilde{x}, \tilde{x}') = f(\tilde{x})f(\tilde{x}')$  $\max \mathbb{E}[\|f_{(2)}\|_{\infty}^p] < \infty$  for all  $1 \leq p < \infty$  and so  $f_{(2)} \in L_p(\Omega, \mathcal{F}, \mathbb{P}, \mathcal{C}(\tilde{\mathbb{X}} \times \tilde{\mathbb{X}})).$  Thus, by [\(Pisier, 2016,](#page-21-14) Theorems 1.14 and 1.30),  $\mu_{(2)}^n \to \mu_{(2)}^\infty$  almost surely and in  $L_p(\Omega, \mathcal{F}, \mathbb{P}, \mathcal{C}(\tilde{\mathbb{X}} \times \tilde{\mathbb{X}}))$ , where  $\mu_{(2)}^\infty(\tilde{x}, \tilde{x}')$  $\mathbb{E}[f(\tilde{\boldsymbol{x}})f(\tilde{\boldsymbol{x}}') | \mathcal{F}^{\infty}]$ . Therefore,  $k^n \to k^{\infty}$  uniformly both almost surely and in  $L_p(\Omega, \mathcal{F}, \mathbb{P}, \mathcal{C}(\tilde{\mathbb{X}} \times \tilde{\mathbb{X}}))$ , since  $k^{n}(\tilde{x}, \tilde{x}') = \mu_{(2)}^{n}(\tilde{x}, \tilde{x}') - \mu^{n}(\tilde{x})\mu^{n}(\tilde{x}')$  for all  $n \in \mathbb{N}_{0} \cup \{\infty\}$ . Finally,  $k^{\infty}$  has continuous sample paths, since it is a random element in  $\mathcal{C}(\mathbb{X}\times\mathbb{X})$ .  $\Box$ 

We now prove the analogous result of Proposition [A.11](#page-28-1) for the average performance objective,  $\bar{f}$ . For each  $n \in \mathbb{N}_0 \cup \{\infty\},\ x, x' \in \mathbb{X}$  and  $g, g' : \mathbb{U} \to \mathbb{Y}$ , define the posterior mean and covariance functions of  $\overline{f}$  as

$$
\overline{\mu}^n(\boldsymbol{x}, \boldsymbol{g}) = \mathbb{E}[\overline{f}(\boldsymbol{x}, \boldsymbol{g}) \, | \, \mathcal{F}^n],\tag{30a}
$$

$$
\overline{k}^{n}(\boldsymbol{x},\boldsymbol{g};\,\boldsymbol{x}',\boldsymbol{g}') = \text{Cov}[\overline{f}(\boldsymbol{x},\boldsymbol{g}),\overline{f}(\boldsymbol{x}',\boldsymbol{g}') \,|\,\mathcal{F}^{n}]. \tag{30b}
$$

Note that we do not include a statement of continuity of  $\overline{\mu}^{\infty}$  and  $\overline{k}^{\infty}$  since we have not defined a topology on the set  $\mathbb{X} \times \{ \mathbb{U} \to \mathbb{Y} \}.$ 

<span id="page-28-0"></span>**Proposition A.12.** For any choice of design points  $\tilde{\mathbf{x}}^1, \tilde{\mathbf{x}}^2, \ldots$ , the sequences of stochastic processes  $\overline{\mu}^n \to$  $\overline{\mu}^{\infty}$  and  $\overline{k}^n \to \overline{k}^{\infty}$  converge uniformly as  $n \to \infty$ , both almost surely and in  $L^p$  for all  $1 \leq p < \infty$ .

*Proof.* Let  $n \in \mathbb{N}_0$ . Then

$$
\sup_{\substack{\mathbf{x}\in\mathbb{X}\\ \mathbf{g}: \mathbb{U}\to \mathbb{Y}}} \left|\overline{\mu}^n(\mathbf{x},\mathbf{g}) - \overline{\mu}^{\infty}(\mathbf{x},\mathbf{g})\right| \leq \sup_{\substack{\mathbf{x}\in\mathbb{X}\\ \mathbf{y}\in \mathbb{Y}\\ \mathbf{u}\in \mathbb{U}}} \left|\mu^n(\mathbf{x},\mathbf{y},\mathbf{u}) - \mu^{\infty}(\mathbf{x},\mathbf{y},\mathbf{u})\right| \to 0
$$

as  $n \to \infty$ , both almost surely and in  $L^p$  for all  $1 \leq p < \infty$  by Proposition [A.11.](#page-28-1) Similarly,

$$
\sup_{\substack{\mathbf{x},\mathbf{x}'\in\mathbb{X}\\ \mathbf{g},\mathbf{g}':\mathbb{U}\rightarrow\mathbb{Y}}} \left|\overline{k}^n(\mathbf{x},\mathbf{g};\,\mathbf{x}',\mathbf{g}')-\overline{k}^\infty(\mathbf{x},\mathbf{g};\,\mathbf{x}',\mathbf{g}')\right|\leq \sup_{\tilde{\mathbf{x}},\tilde{\mathbf{x}}'\in\tilde{\mathbb{X}}} \left|k^n(\tilde{\mathbf{x}},\tilde{\mathbf{x}}')-k^\infty(\tilde{\mathbf{x}},\tilde{\mathbf{x}}')\right|\rightarrow 0
$$

as  $n \to \infty$ , both almost surely and in  $L^p$  for all  $1 \leq p < \infty$  again by Proposition [A.11.](#page-28-1)

<span id="page-29-1"></span>We finish this section with a lemma which will be useful later, and which is also proved using Lemma [A.9.](#page-27-1) **Lemma A.13.** All moments of the supremum of  $|\overline{f}|$  are finite. That is,

$$
\forall 1 \leq p < \infty \qquad \mathbb{E}\Bigg[\bigg(\sup_{\substack{\mathbf{x}\in \mathbb{X} \\ \mathbf{g}: \mathbb{U}\to \mathbb{Y}}} |\overline{f}(\mathbf{x},\mathbf{g})|\bigg)^p\Bigg] < \infty.
$$

*Proof.* Let  $1 \leq p < \infty$ . From Lemma [A.9](#page-27-1) we have  $\mathbb{E}[\sup_{\mathbf{x},\mathbf{y},\mathbf{u}}|f(\mathbf{x},\mathbf{y},\mathbf{u})|^p] < \infty$ . Therefore,

$$
\mathbb{E}\Bigg[\bigg(\sup_{\substack{\mathbf{x}\in\mathbb{X}\\ \mathbf{g}: \mathbb{U}\to\mathbb{Y}}}\left|\overline{f}(\mathbf{x},\mathbf{g})\right| \bigg)^p\Bigg] = \mathbb{E}\Bigg[\bigg(\sup_{\substack{\mathbf{x}\in\mathbb{X}\\ \mathbf{g}: \mathbb{U}\to\mathbb{Y}}}\left|\mathbb{E}_{\mathbf{u}}\big[f(\mathbf{x},\mathbf{g}(\mathbf{u}),\mathbf{u})\big]\right|\bigg)^p\Bigg] \leq \mathbb{E}\Bigg[\sup_{\mathbf{x},\mathbf{y},\mathbf{u}}|f(\mathbf{x},\mathbf{y},\mathbf{u})|^p\Bigg] < \infty.
$$

#### **A.4 Convergence to optimal recommendations**

The main result in this section is to prove Theorem [3.2](#page-6-2) from the main text. That is, that the objective values of the recommendations generated using joint knowledge gradient converge to the optimal values. The lions share of the work is done by the following proposition, which shows that the limiting covariance function  $\overline{k}^{\infty}$  is pointwise almost surely constant. This is then used in Proposition [A.15](#page-31-1) to show that the limiting posterior mean  $\overline{\mu}^{\infty}$  is pointwise almost surely equal to  $\overline{f}$  up to a constant. The result is extended to show that the sample paths are almost surely equal up to a constant in Proposition [A.16](#page-31-0) and from this we deduce the convergence of the values of the recommendations the the supremum of  $\overline{f}$ .

<span id="page-29-0"></span>**Proposition A.14.** *There exists a random variable*  $c_1 \in \mathbb{R}$  *such that for all*  $x, x' \in \mathbb{X}$  *and*  $g, g' : \mathbb{U} \to \mathbb{Y}$ *,* 

$$
\mathbb{P}\bigg(\overline{k}^{\infty}(\boldsymbol{x},\boldsymbol{g};\,\boldsymbol{x}',\boldsymbol{g}')=\mathrm{c}_1\bigg)=1.
$$

Intuitively, we might want to show that we can take  $c_1 = 0$  here, but this turns out not to be necessary for the proof of Theorem [3.2.](#page-6-2)

*Proof.* By Lemma [A.3,](#page-25-3) the posterior mean  $\bar{\mu}^n(x, g) = \mathbb{E}_{\mathbf{u}}[f(x, g(\mathbf{u}), \mathbf{u})]$  attains its bounds, for each *n*. Thus, for each  $n \in \mathbb{N}_0$ , let  $\mathbf{x}^{*n}, \mathbf{g}^{*n} \in \arg \max_{\mathbf{x}, \mathbf{g}} \overline{\mu}^n(\mathbf{x}, \mathbf{g})$  and for each  $\tilde{\mathbf{x}} \in \mathbb{X}, \mathbf{x}' \in \mathbb{X}$  and  $\mathbf{g}' : \mathbb{U} \to \mathbb{Y}$  let

$$
\mathbf{w}_{\tilde{\boldsymbol{x}}}^n(\boldsymbol{x}', \boldsymbol{g}') = \mathbb{E}\Big[\overline{f}(\boldsymbol{x}', \boldsymbol{g}') - \overline{f}(\mathbf{x}^{*n}, \mathbf{g}^{*n})\,\Big|\,\mathcal{F}^n, \mathbf{v}_{\tilde{\boldsymbol{x}}}\Big]
$$

where  $v_{\tilde{\bm{x}}} = f(\tilde{\bm{x}}) + \varepsilon$  is a hypothesized noisy observation at  $\tilde{\bm{x}}$  with  $\varepsilon \sim \mathcal{N}(0, \sigma^2)$ . Thus, for each  $\tilde{\bm{x}} \in \tilde{\mathbb{X}}$ ,  $\alpha_{j\text{KG}}^n(\tilde{\pmb{x}}) = \mathbb{E}[\sup_{\pmb{x}', \pmb{g}'} \text{w}_{\tilde{\pmb{x}}}^n(\pmb{x}', \pmb{g}') \, | \, \mathcal{F}^n].$ 

We will show that in the limit  $n \to \infty$ , the  $w_{\tilde{\bm{x}}}^n(\bm{x}', \bm{g}')$  are uniformly not very positive, and use this to deduce the proposition statement.

 $\Box$ 

*Claim.* Let  $\delta > 0$ . There exists a random sequence  $(\rho_{\delta}^n)_{n=0}^{\infty}$  with  $\rho_{\delta}^n \to 0$  almost surely as  $n \to \infty$ , such that for all  $\tilde{x} \in \tilde{\mathbb{X}}, x' \in \mathbb{X}$  and  $g' : \mathbb{U} \to \mathbb{Y}$  and for all  $n \in \mathbb{N}_0$ , the conditional probabilities  $\mathbb{P}(w_{\tilde{x}}^n(x', g') >$  $\delta | \mathcal{F}^n$ )  $\leq \rho_{\delta}^n$  almost surely.

Let  $\tilde{\mathbf{x}} \in \mathbb{\tilde{X}}, \mathbf{x}' \in \mathbb{X}, \mathbf{g}' : \mathbb{U} \to \mathbb{Y}$  and  $\delta > 0$ . Certainly,  $\sup_{\mathbf{x}'',\mathbf{g}''} w_{\tilde{\mathbf{x}}}^n(\mathbf{x}'',\mathbf{g}'') \geq 0$  and so  $\sup_{\mathbf{x}'',\mathbf{g}''} w_{\tilde{\mathbf{x}}}^n(\mathbf{x}'',\mathbf{g}'') =$  $\sup_{\mathbf{x''},\mathbf{g''}} \max \{ \mathbf{w}_{\tilde{\mathbf{x}}}^n(\mathbf{x''},\mathbf{g''}),0 \}$  almost surely. Therefore, by Markov's inequality,

$$
0 \leq \delta \mathbb{P} \Big( \mathbf{w}_{\tilde{\mathbf{x}}}^n(\mathbf{x}', \mathbf{g}') > \delta \Big| \mathcal{F}^n \Big)
$$
  
\n
$$
\leq \mathbb{E} \Big[ \max \{ \mathbf{w}_{\tilde{\mathbf{x}}}^n(\mathbf{x}', \mathbf{g}'), 0 \} \Big| \mathcal{F}^n \Big]
$$
  
\n
$$
\leq \mathbb{E} \Big[ \sup_{\mathbf{x}'', \mathbf{g}''} \max \{ \mathbf{w}_{\tilde{\mathbf{x}}}^n(\mathbf{x}'', \mathbf{g}''), 0 \} \Big| \mathcal{F}^n \Big]
$$
  
\n
$$
= \mathbb{E} \Big[ \sup_{\mathbf{x}'', \mathbf{g}''} \mathbf{w}_{\tilde{\mathbf{x}}}^n(\mathbf{x}'', \mathbf{g}'') \Big| \mathcal{F}^n \Big] = \alpha_{\text{IKG}}^n(\tilde{\mathbf{x}}) \leq \sup_{\tilde{\mathbf{x}}} \alpha_{\text{IKG}}^n(\tilde{\mathbf{x}}) \to 0 \quad \text{a.s.}
$$

as  $n \to \infty$  by Theorem [A.10.](#page-27-0) That is,  $\mathbb{P}(w_{\tilde{x}}^n(x', g') > \delta | \mathcal{F}^n) \leq \rho_{\delta}^n \to 0$  almost surely as  $n \to \infty$ , where  $\rho_{\delta}^{n} = \delta^{-1} \sup_{\tilde{\mathbf{x}}} \alpha_{jKG}^{n}(\tilde{\mathbf{x}})$ . This establishes the claim.

As in the claim, let  $\tilde{x} \in \tilde{X}$ ,  $x' \in X$ ,  $g' : \mathbb{U} \to \mathbb{Y}$ . Also, let **u**' be an independent copy of **u**. Write  $\tilde{\mathbf{x}}' = (\mathbf{x}', g'(\mathbf{u}'), \mathbf{u}') \text{ and } \tilde{\mathbf{x}}^{*n} = (\mathbf{x}^{*n}, g^{*n}(\mathbf{u}'), \mathbf{u}')$ .

We will first show that  $\mathbb{E}_{\mathbf{u}'}[k^n(\tilde{\mathbf{x}}', \tilde{\mathbf{x}})] - \mathbb{E}_{\mathbf{u}'}[k^n(\tilde{\mathbf{x}}^{*n}, \tilde{\mathbf{x}})] \to 0$  uniformly in  $\tilde{\mathbf{x}}$  as  $n \to 0$ , almost surely.

If for some  $n \in \mathbb{N}$ ,  $k^n(\tilde{x}, \tilde{x}) = 0$ , then  $k^{n'}(\tilde{x}, \tilde{x}) = 0$  for all  $n' > n$  as well. Therefore, by Cauchy-Schwarz,  $k^{n'}(\tilde{\mathbf{x}}, \tilde{\mathbf{x}}) = k^{n'}(\tilde{\mathbf{x}}^{*n'}, \tilde{\mathbf{x}}) = 0$  almost surely and so  $\mathbb{E}_{\mathbf{u}'}[k^{n'}(\tilde{\mathbf{x}}', \tilde{\mathbf{x}})] = \mathbb{E}_{\mathbf{u}'}[k^{n'}(\tilde{\mathbf{x}}^{*n'}, \tilde{\mathbf{x}})] = 0$  for all  $n' > n$ .

Otherwise assume that, for all *n*,  $k^n(\tilde{x}, \tilde{x}) > 0$  and hence  $k^n(\tilde{x}, \tilde{x}) + \sigma^2 > 0$ . The posterior mean of  $f(\tilde{\mathbf{x}}') = f(\mathbf{x}', \mathbf{g}'(\mathbf{u}'), \mathbf{u}')$  conditional on  $\mathcal{F}^n$ ,  $v_{\tilde{\mathbf{x}}}$  and  $\mathbf{u}'$  is [\(Rasmussen & Williams, 2006,](#page-21-9) Equation 2.38)

$$
\mathbb{E}[f(\tilde{\mathbf{x}}') | \mathcal{F}^n, \mathbf{v}_{\tilde{\mathbf{x}}}, \mathbf{u}'] = \mu^n(\tilde{\mathbf{x}}') + k^n(\tilde{\mathbf{x}}', \tilde{\mathbf{x}}) \big(k^n(\tilde{\mathbf{x}}, \tilde{\mathbf{x}}) + \sigma^2\big)^{-1} \big(\mathbf{v}_{\tilde{\mathbf{x}}} - \mu^n(\tilde{\mathbf{x}})\big).
$$

Therefore,

$$
w_{\tilde{x}}^{n}(\boldsymbol{x}',\boldsymbol{g}') = \mathbb{E}\Big[\overline{f}(\boldsymbol{x}',\boldsymbol{g}') - \overline{f}(\boldsymbol{x}^{*n},\boldsymbol{g}^{*n})\Big|\mathcal{F}^{n},v_{\tilde{\boldsymbol{x}}}\Big] = \mathbb{E}_{\mathbf{u}'}\left[\mu^{n}(\tilde{\mathbf{x}}') - \mu^{n}(\tilde{\mathbf{x}}^{*n}) + \frac{k^{n}(\tilde{\mathbf{x}}',\tilde{\boldsymbol{x}}) - k^{n}(\tilde{\mathbf{x}}^{*n},\tilde{\boldsymbol{x}})}{k^{n}(\tilde{\boldsymbol{x}},\tilde{\boldsymbol{x}}) + \sigma^{2}}(v_{\tilde{\boldsymbol{x}}} - \mu^{n}(\tilde{\boldsymbol{x}}))\right] = \overline{\mu}^{n}(\boldsymbol{x}',\boldsymbol{g}') - \overline{\mu}^{n}(\mathbf{x}^{*n},\mathbf{g}^{*n}) + \frac{\mathbb{E}_{\mathbf{u}'}[k^{n}(\tilde{\mathbf{x}}',\tilde{\boldsymbol{x}})] - \mathbb{E}_{\mathbf{u}'}[k^{n}(\tilde{\mathbf{x}}^{*n},\tilde{\boldsymbol{x}})]}{k^{n}(\tilde{\boldsymbol{x}},\tilde{\boldsymbol{x}}) + \sigma^{2}}(v_{\tilde{\boldsymbol{x}}} - \mu^{n}(\tilde{\boldsymbol{x}})).
$$

Since  $v_{\tilde{\bm{x}}}\,|\,\mathcal{F}^n \sim \mathcal{N}(\mu^n(\tilde{\bm{x}}), k^n(\tilde{\bm{x}}, \tilde{\bm{x}}) + \sigma^2)$ , we therefore have that  $w_{\tilde{\bm{x}}}^n(\bm{x}', \bm{g}')\,|\,\mathcal{F}^n$  is Gaussian with

$$
\mathbb{E}[\mathbf{w}_{\tilde{\mathbf{x}}}^{n}(\mathbf{x}', \mathbf{g}') | \mathcal{F}^{n}] = \overline{\mu}^{n}(\mathbf{x}', \mathbf{g}') - \overline{\mu}^{n}(\mathbf{x}^{*n}, \mathbf{g}^{*n}),
$$
  
\n
$$
\text{Var}[\mathbf{w}_{\tilde{\mathbf{x}}}^{n}(\mathbf{x}', \mathbf{g}') | \mathcal{F}^{n}] = \frac{\left(\mathbb{E}_{\mathbf{u}'}[k^{n}(\tilde{\mathbf{x}}', \tilde{\mathbf{x}})] - \mathbb{E}_{\mathbf{u}'}[k^{n}(\tilde{\mathbf{x}}^{*n}, \tilde{\mathbf{x}})]\right)^{2}}{k^{n}(\tilde{\mathbf{x}}, \tilde{\mathbf{x}}) + \sigma^{2}}
$$

*.*

Thus, writing  $\Phi(\cdot)$  for the cumulative density function of a standard normal variable, and letting  $\delta > 0$ ,  $\text{either } \mathbb{E}_{\mathbf{u}'}[k^n(\tilde{\mathbf{x}}', \tilde{\mathbf{x}})] - \mathbb{E}_{\mathbf{u}'}[k^n(\tilde{\mathbf{x}}^{*n}, \tilde{\mathbf{x}})] = 0 \text{ or }$ 

$$
\mathbb{P}(\mathbf{w}_{\tilde{\mathbf{x}}}^n(\mathbf{x}',\mathbf{g}') > \delta | \mathcal{F}^n) = 1 - \Phi\left(\frac{\sqrt{k^n(\tilde{\mathbf{x}},\tilde{\mathbf{x}}) + \sigma^2}}{\left|\mathbb{E}_{\mathbf{u}'}[k^n(\tilde{\mathbf{x}}',\tilde{\mathbf{x}})] - \mathbb{E}_{\mathbf{u}'}[k^n(\tilde{\mathbf{x}}^{*n},\tilde{\mathbf{x}})]\right|} \left[\delta - (\overline{\mu}^n(\mathbf{x}',\mathbf{g}') - \overline{\mu}^n(\mathbf{x}^{*n},\mathbf{g}^{*n}))\right]\right).
$$

By Proposition [A.12,](#page-28-0)  $\overline{\mu}^n \to \overline{\mu}^{\infty}$  uniformly, almost surely as  $n \to \infty$ . Further, the same argument as in Lemma [A.3](#page-25-3) shows that  $\bar{\mu}^{\infty}$  is bounded and attains its bounds. Therefore, there exists a negative random

variable b (not depending on *n*) such that for sufficiently large  $n, \overline{\mu}^n(\mathbf{x}', \mathbf{g}') - \overline{\mu}^n(\mathbf{x}^{*n}, \mathbf{g}^{*n}) > b$ . For example, take any  $b < \min \overline{\mu}^{\infty} - \max \overline{\mu}^{\infty}$ . Then, almost surely,

$$
\mathbb{P}(\mathbf{w}_{\tilde{\boldsymbol{x}}}^n(\boldsymbol{x}', \boldsymbol{g}') > \delta | \mathcal{F}^n) \geq 1 - \Phi\left(\frac{\sqrt{k^n(\tilde{\boldsymbol{x}}, \tilde{\boldsymbol{x}}) + \sigma^2}}{\left|\mathbb{E}_{\mathbf{u}'}[k^n(\tilde{\mathbf{x}}', \tilde{\boldsymbol{x}})] - \mathbb{E}_{\mathbf{u}'}[k^n(\tilde{\mathbf{x}}^{*n}, \tilde{\boldsymbol{x}})]\right|} (\delta - b)\right).
$$

In the claim, we showed that the left hand side here converges to zero uniformly in  $\tilde{x}$  almost surely as  $n \to \infty$ . Therefore, so must the right hand side and we must have  $\mathbb{E}_{\mathbf{u}'}[k^n(\tilde{\mathbf{x}}', \tilde{\mathbf{x}})] - \mathbb{E}_{\mathbf{u}'}[k^n(\tilde{\mathbf{x}}^{*n}, \tilde{\mathbf{x}})] \to 0$  uniformly in  $\tilde{x}$ , almost surely.

Thus, in all cases, we have shown  $\mathbb{E}_{\mathbf{u}'}[k^n(\tilde{\mathbf{x}}', \tilde{\mathbf{x}})] - \mathbb{E}_{\mathbf{u}'}[k^n(\tilde{\mathbf{x}}^{*n}, \tilde{\mathbf{x}})] \to 0$  uniformly in  $\tilde{\mathbf{x}}$ , almost surely. Let  $g: \mathbb{U} \to \mathbb{Y}$ . Since convergence is uniform in  $\tilde{x}$ , we may integrate over **u** in  $\tilde{x} = (x, g(u), u)$  to give

$$
\overline{k}^{n}(\mathbf{x}', \mathbf{g}'; \mathbf{x}, \mathbf{g}) - \overline{k}^{n}(\mathbf{x}^{*n}, \mathbf{g}^{*n}; \mathbf{x}, \mathbf{g}) = \mathbb{E}_{\mathbf{u}, \mathbf{u}'}[k^{n}(\tilde{\mathbf{x}}', \tilde{\mathbf{x}}) - k^{n}(\tilde{\mathbf{x}}^{*n}, \tilde{\mathbf{x}})] \rightarrow 0
$$

almost surely as  $n \to \infty$ . Further, from Proposition [A.12,](#page-28-0)  $\overline{k}^n \to \overline{k}^{\infty}$  uniformly, almost surely, so

$$
\overline{k}^{\infty}(\mathbf{x}', \mathbf{g}'; \, \mathbf{x}, \mathbf{g}) - \overline{k}^{\infty}(\mathbf{x}^{*n}, \mathbf{g}^{*n}; \, \mathbf{x}, \mathbf{g}) \to 0 \qquad \text{a.s.}
$$

This holds for any  $x', g'$ , including  $x' = x$  and  $g' = g$ , so

$$
\overline{k}^{\infty}(x',g';x,g)-\overline{k}^{\infty}(x,g;x,g)=\\\left(\overline{k}^{\infty}(x',g';x,g)-\overline{k}^{\infty}(x^{*n},g^{*n};x,g)\right)-\left(\overline{k}^{\infty}(x,g;x,g)-\overline{k}^{\infty}(x^{*n},g^{*n};x,g)\right)\to 0 \quad \text{a.s.}
$$

as  $n \to \infty$ . The left hand side is independent of *n*, so therefore must equal zero almost surely. Thus, by symmetry of  $\overline{k}^{\infty}$ , we conclude that for any  $x_A, x'_A, x_B, x'_B \in \mathbb{X}$  and  $g_A, g'_A, g_B, g'_B : \mathbb{U} \to \mathbb{Y}$ ,

$$
\overline{k}^{\infty}(\boldsymbol{x}_A,\boldsymbol{g}_A;\,\boldsymbol{x}_A',\boldsymbol{g}_A')=\overline{k}^{\infty}(\boldsymbol{x}_B,\boldsymbol{g}_B;\,\boldsymbol{x}_B',\boldsymbol{g}_B')
$$

<span id="page-31-1"></span>almost surely. Taking  $c_1 = \overline{k}^{\infty}(\boldsymbol{x}_A, \boldsymbol{g}_A; \boldsymbol{x}_A', \boldsymbol{g}_A')$  for any choice of  $\boldsymbol{x}_A, \boldsymbol{g}_A, \boldsymbol{x}_A', \boldsymbol{g}_A'$  completes the proof.  $\Box$ **Proposition A.15.** *There exists a random variable*  $c_2$  *such that for all*  $\mathbf{x} \in \mathbb{X}$  *and all*  $\mathbf{g} : \mathbb{U} \to \mathbb{Y}$ *, we have* 

$$
\mathbb{P}\bigg(\overline{f}(\boldsymbol{x}, \boldsymbol{g}) = \overline{\mu}^{\infty}(\boldsymbol{x}, \boldsymbol{g}) + c_2\bigg) = 1.
$$

*Proof.* Let  $x, x' \in \mathbb{X}$  and  $g, g' : \mathbb{U} \to \mathbb{Y}$ . Then

$$
\operatorname{Var}\Big[\big(\overline{f}(\boldsymbol{x},\boldsymbol{g})-\overline{\mu}^{\infty}(\boldsymbol{x},\boldsymbol{g})\big)-\big(\overline{f}(\boldsymbol{x}',\boldsymbol{g}')-\overline{\mu}^{\infty}(\boldsymbol{x}',\boldsymbol{g}')\big)\,\Big|\,\mathcal{F}^{\infty}\Big] \\ =\underbrace{k^{\infty}(\boldsymbol{x},\boldsymbol{g};\,\boldsymbol{x},\boldsymbol{g})-k^{\infty}(\boldsymbol{x},\boldsymbol{g};\,\boldsymbol{x}',\boldsymbol{g}')}_{{\scriptstyle{0 \ \text{ a.s.}}}}+\underbrace{k^{\infty}(\boldsymbol{x}',\boldsymbol{g}';\,\boldsymbol{x}',\boldsymbol{g}')-k^{\infty}(\boldsymbol{x}',\boldsymbol{g}';\,\boldsymbol{x},\boldsymbol{g})}_{{\scriptstyle{0 \ \text{ a.s.}}}}=0
$$

almost surely by Proposition [A.14.](#page-29-0) Also,  $\mathbb{E}[(\overline{f}(\bm{x}, \bm{g}) - \overline{\mu}^{\infty}(\bm{x}, \bm{g})) - (\overline{f}(\bm{x}', \bm{g}') - \overline{\mu}^{\infty}(\bm{x}', \bm{g}')) | \mathcal{F}^{\infty}] = 0$  almost surely. Write  $z = (\overline{f}(\boldsymbol{x}, \boldsymbol{g}) - \overline{\mu}^{\infty}(\boldsymbol{x}, \boldsymbol{g})) - (\overline{f}(\boldsymbol{x}', \boldsymbol{g}') - \overline{\mu}^{\infty}(\boldsymbol{x}', \boldsymbol{g}'))$ . The law of total variance gives

$$
Var[z] = \mathbb{E}\big[Var[z|\mathcal{F}^{\infty}]\big] + Var\big[\mathbb{E}[z|\mathcal{F}^{\infty}]\big] = 0.
$$

Therefore, z is a random variable with zero mean and zero variance, and so is almost surely zero. That is,  $\overline{f}(\bm{x},\bm{g})-\overline{\mu}^{\infty}(\bm{x},\bm{g})=\overline{f}(\bm{x}',\bm{g}')-\overline{\mu}^{\infty}(\bm{x}',\bm{g}')\,\,\mathrm{almost\,\, surely.}\,\,\mathrm{Taking}\,\, \mathrm{c}_2=\overline{f}(\bm{x},\bm{g})-\overline{\mu}^{\infty}(\bm{x},\bm{g})\,\,\mathrm{completes\,\, the}$ proof.  $\Box$ 

<span id="page-31-0"></span>Having established that  $\bar{f}$  and  $\bar{\mu}^{\infty}$  are pointwise almost surely equal up to a constant, we now extend this to show that this holds for all points *simultaneously*. That is, that their sample paths are almost surely equal up to a constant.

**Proposition A.16.** *There exists a random variable c*<sup>2</sup> *such that*

$$
\mathbb{P}\bigg(\forall\,\boldsymbol{x}\in\mathbb{X}\ \forall\,\boldsymbol{g}:\mathbb{U}\rightarrow\mathbb{Y}\ \textit{measurable}\qquad \overline{f}(\boldsymbol{x},\boldsymbol{g})=\overline{\mu}^{\infty}(\boldsymbol{x},\boldsymbol{g})+c_2\bigg)=1.
$$

*Proof.* Our strategy for this proof will be to first extend the Proposition [A.15](#page-31-1) to hold for countably many pairs  $(x, g)$  simultaneously. For any pair  $(x, g)$ , we will construct a sequence  $(x^i, g^i) \to (x, g)$  as  $i \to \infty$  but only taking values in a countable set not depending on  $(x, g)$ . We will then use continuity of f and  $\mu^{\infty}$  to conclude that the result must hold for all pairs  $(x, q)$  simultaneously, which is the theorem statement.

The intersection of countably many events with probability 1 has probability 1 by countable subadditivity of measures. Applying this to Proposition [A.15](#page-31-1) with the Cartesian product of X ∩ Q*d<sup>x</sup>* and the set of simple functions  $g: \mathbb{U} \to \mathbb{Y} \cap \mathbb{Q}^{d_y}$  (which is countable), we obtain

<span id="page-32-1"></span>
$$
\mathbb{P}\bigg(\forall \mathbf{x} \in \mathbb{X} \cap \mathbb{Q}^{d_x} \ \forall \mathbf{g} : \mathbb{U} \to \mathbb{Y} \cap \mathbb{Q}^{d_y} \ \text{simple} \qquad \overline{f}(\mathbf{x}, \mathbf{g}) = \overline{\mu}^{\infty}(\mathbf{x}, \mathbf{g}) + c_2\bigg) = 1. \tag{31}
$$

Write *A* for this event.

Let  $x \in \mathbb{X}$  and let  $g: \mathbb{U} \to \mathbb{Y}$  be measurable.

Since  $\mathbb{X} \cap \mathbb{Q}^{d_x}$  is dense in X, we can take a sequence  $x^1, x^2, \dots \in \mathbb{X} \cap \mathbb{Q}^{d_x}$  with  $x^i \to x$  as  $i \to \infty$  Furthermore, since *g* is measurable, we can write  $g(u) = \lim_{i \to \infty} g^i(u)$  as a pointwise limit of simple functions,  $(g^i)_{i=1}^{\infty}$ , by applying [\(Klenke, 2020,](#page-20-12) Theorem 1.96) to the positive and negative parts of each component of *g*. Since  $\mathbb{Y} \cap \mathbb{Q}^{d_y}$  is dense in Y, we can assume the  $g^1, g^2, \ldots$  take values in  $\mathbb{Y} \cap \mathbb{Q}^{d_y}$ . The sample paths of  $f - \mu^\infty$  are continuous, and therefore for any  $u \in \mathbb{U}$ ,

$$
f(\boldsymbol{x}^i,\boldsymbol{g}^i(\boldsymbol{u}),\boldsymbol{u})-\mu^\infty(\boldsymbol{x}^i,\boldsymbol{g}^i(\boldsymbol{u}),\boldsymbol{u})\rightarrow f(\boldsymbol{x},\boldsymbol{g}(\boldsymbol{u}),\boldsymbol{u})-\mu^\infty(\boldsymbol{x},\boldsymbol{g}(\boldsymbol{u}),\boldsymbol{u})
$$

almost surely as  $i \to \infty$ . The expectation  $\mathbb{E}_{\mathbf{u}}$  is formally an expectation conditional on the sigma algebra  $\sigma(f, \mathcal{F}^{\infty})$  (i.e. on everything except **u**). Therefore, the Dominated Convergence Theorem for conditional expectation [\(Klenke, 2020,](#page-20-12) Theorem 8.14 (viii)) with max  $|f - \mu^{\infty}|$  as a (constant) dominating function, the expectation over **u** also converges almost surely

$$
\underbrace{\mathbb{E}_{\mathbf{u}}\Big[f(\mathbf{x}^i,\mathbf{g}^i(\mathbf{u}),\mathbf{u})-\mu^{\infty}(\mathbf{x}^i,\mathbf{g}^i(\mathbf{u}),\mathbf{u})\Big]}_{\overline{f}(\mathbf{x}^i,\mathbf{g}^i)-\overline{\mu}^{\infty}(\mathbf{x},\mathbf{g}^i)} \rightarrow \underbrace{\mathbb{E}_{\mathbf{u}}\Big[f(\mathbf{x},\mathbf{g}(\mathbf{u}),\mathbf{u})-\mu^{\infty}(\mathbf{x},\mathbf{g}(\mathbf{u}),\mathbf{u})\Big]}_{\overline{f}(\mathbf{x},\mathbf{g})-\overline{\mu}^{\infty}(\mathbf{x},\mathbf{g})}.
$$

On the event *A* considered in Equation [\(31\)](#page-32-1), each term in the sequence on the left hand side is equal to  $c_2$ , and therefore the limit on the right must equal c<sub>2</sub> as well. Whence, on *A*,  $\overline{f}(x, g) - \overline{\mu}^{\infty}(x, g) = c_2$ . Our choice of *x* and *g* was arbitrary, and so

$$
\mathbb{P}\bigg(\forall\, \boldsymbol{x}\in\mathbb{X}\ \forall\, \boldsymbol{g}:\mathbb{U}\to\mathbb{Y}\,\,\textrm{measurable}\qquad \overline{f}(\boldsymbol{x},\boldsymbol{g})=\overline{\mu}^{\infty}(\boldsymbol{x},\boldsymbol{g})+c_2\bigg)=1.
$$

 $\Box$ 

We can now prove Theorem [3.2](#page-6-2) from the main text, which we restate here for convenience.

<span id="page-32-0"></span>**Theorem A.17** (Consistency of Joint KG)**.** *When using joint knowledge gradient as an acquisition function, the objective values associated with the recommendations converge to the optimal value both almost surely and in mean. That is,*

$$
\overline{f}(\mathbf{x}^{*n}, \mathbf{g}^{*n}) \to \sup_{\substack{\mathbf{x} \in \mathbb{X} \\ \mathbf{g} : \mathbb{U} \to \mathbb{Y}}} \overline{f}(\mathbf{x}, \mathbf{g}) \qquad as \qquad n \to \infty
$$

*almost surely and in mean.*

*Proof.* By Lemma [A.2,](#page-24-0)  $\overline{f}$  is bounded and attains its bounds, so let  $\mathbf{x}^*, \mathbf{g}^* \in \arg \max_{\mathbf{x}, \mathbf{g}} \overline{f}(\mathbf{x}, \mathbf{g})$  be random elements maximizing  $\overline{f}$ . For any  $n$ ,  $\overline{f}(\mathbf{x}^{*n}, \mathbf{g}^{*n}) \leq \sup_{\mathbf{x}, \mathbf{g}} \overline{f}(\mathbf{x}, \mathbf{g})$  almost surely. Therefore, it suffices to prove that  $\limsup_{n\to\infty} \overline{f}(\mathbf{x}^*, \mathbf{g}^*) - \overline{f}(\mathbf{x}^{*n}, \mathbf{g}^{*n}) = 0.$ 

Splitting this limit, we have

$$
\limsup_{n\to\infty} \overline{f}(\mathbf{x}^*, \mathbf{g}^*) - \overline{f}(\mathbf{x}^{*n}, \mathbf{g}^{*n})
$$
\n
$$
\leq \limsup_{n\to\infty} (\overline{f}(\mathbf{x}^*, \mathbf{g}^*) - \overline{\mu}^{\infty}(\mathbf{x}^*, \mathbf{g}^*)) - (\overline{f}(\mathbf{x}^{*n}, \mathbf{g}^{*n}) - \overline{\mu}^{\infty}(\mathbf{x}^{*n}, \mathbf{g}^{*n}))
$$
\n
$$
+ \limsup_{n\to\infty} (\overline{\mu}^{\infty}(\mathbf{x}^*, \mathbf{g}^*) - \overline{\mu}^n(\mathbf{x}^*, \mathbf{g}^*)) - (\overline{\mu}^{\infty}(\mathbf{x}^{*n}, \mathbf{g}^{*n}) - \overline{\mu}^n(\mathbf{x}^{*n}, \mathbf{g}^{*n}))
$$
\n
$$
+ \limsup_{n\to\infty} \overline{\mu}^n(\mathbf{x}^*, \mathbf{g}^*) - \overline{\mu}^n(\mathbf{x}^{*n}, \mathbf{g}^{*n}).
$$

By Lemmas [A.2](#page-24-0) and [A.3,](#page-25-3)  $g^*$  and the  $g^{*n}$  have measurable sample paths, and so by Proposition [A.16,](#page-31-0) for each *n*,

$$
\left(\overline{f}(\mathbf{x}^*, \mathbf{g}^*) - \overline{\mu}^{\infty}(\mathbf{x}^*, \mathbf{g}^*)\right) - \left(\overline{f}(\mathbf{x}^{*n}, \mathbf{g}^{*n}) - \overline{\mu}^{\infty}(\mathbf{x}^{*n}, \mathbf{g}^{*n})\right) = c_2 - c_2 = 0
$$

almost surely. Then by countable subadditivity of measures, this holds for all *n* simultaneously, and so the lim sup in the first line is almost surely zero.

Since  $\overline{\mu}^n \to \overline{\mu}^{\infty}$  uniformly, almost surely, as  $n \to \infty$  (Proposition [A.12\)](#page-28-0), the second line is also almost surely zero. Finally, the third line line is at most zero by optimality of  $\mathbf{x}^{*n}, \mathbf{g}^{*n}$ . Therefore,

$$
\limsup_{n\to\infty} \overline{f}(\mathbf{x}^*, \mathbf{g}^*) - \overline{f}(\mathbf{x}^{*n}, \mathbf{g}^{*n}) \le 0
$$

and since  $\overline{f}(\mathbf{x}^*, \mathbf{g}^*) - \overline{f}(\mathbf{x}^{*n}, \mathbf{g}^{*n}) \ge 0$  almost surely as well, we conclude that  $\overline{f}(\mathbf{x}^{*n}, \mathbf{g}^{*n}) \to \overline{f}(\mathbf{x}^*, \mathbf{g}^*)$  almost surely as  $n \to \infty$ .

To establish convergence in mean, we appeal to the Dominated Convergence Theorem with dominating variable sup<sub>**x**,**g**  $|f(\mathbf{x}, \mathbf{g})|$ . Indeed, this has finite expectation by Lemma [A.13.](#page-29-1)</sub> П

# <span id="page-33-0"></span>**B Caching of the covariances**

Computation of the discrete knowledge gradient naively requires recomputing many covariances. It is common in inference with Gaussian processes to cache the covariances between the training data to improve performance. Performance can be further improved by caching the cross covariances between the training data and the discretization used to compute the discrete knowledge gradient, which is not done automatically by libraries such as GPyTorch [\(Gardner et al., 2018\)](#page-19-12).

Recall the formula for the discrete knowledge gradient approximation applicable to standard (not two-stage) optimization problem  $h : \mathbb{X} \to \mathbb{R}$  from Equation [\(6\)](#page-5-3) was given in the background section as

$$
\hat{\alpha}_{\text{KG}}^n(\boldsymbol{x}) = \frac{1}{N_v} \sum_{i=1}^{N_v} \max_{\boldsymbol{x}' \in \mathbb{X}_{\text{disc}}} \mu^{n+1}(\boldsymbol{x}'; \boldsymbol{x}, \tilde{v}^{n+1,i}) - \max_{\boldsymbol{x}' \in \mathbb{X}_{\text{disc}}} \mu^n(\boldsymbol{x}'). \tag{32}
$$

Here,  $\tilde{v}^{n+1,1}, \ldots, \tilde{v}^{n+1,N_v}$  are independent samples of the next observation  $v^{n+1} = f(x) + \varepsilon^{n+1}$ , conditional on the the *n* observations made so far. For any  $x' \in \mathbb{X}_{\text{disc}}$  in the discretization, the posterior mean is computed using [\(Rasmussen & Williams, 2006,](#page-21-9) Equation 2.38) as

$$
\mu^{n+1}(\mathbf{x}'; \mathbf{x}, \tilde{v}^{n+1,i}) = \mu^n(\mathbf{x}') + k^n(\mathbf{x}', \mathbf{x})\left(k^n(\mathbf{x}, \mathbf{x}) + \sigma^2\right)^{-1}(\tilde{v}^{n+1,i} - \mu^n(\mathbf{x})).
$$
\n(33)

As the acquisition function is optimized,  $\hat{\alpha}_{\text{KG}}^n(x)$  and its gradient are evaluated at many different  $x \in \mathbb{X}$ , and there are three potentially costly computations involved:  $\mu^{n}(\mathbf{x}'), k^{n}(\mathbf{x}', \mathbf{x})$  and  $k^{n}(\mathbf{x}, \mathbf{x})$ .

From Equation 2.24 in [\(Rasmussen & Williams, 2006\)](#page-21-9)

$$
k^{n}(\boldsymbol{x},\boldsymbol{x}) = k(\boldsymbol{x},\boldsymbol{x}) - k(\boldsymbol{x},\boldsymbol{X}^{n})(\boldsymbol{K}(\boldsymbol{X}^{1:n},\boldsymbol{X}^{1:n}) + \sigma^{2}\boldsymbol{I})^{-1}\boldsymbol{k}(\boldsymbol{X}^{1:n},\boldsymbol{x}),
$$
\n(34)

where  $X^{1:n}$  is a matrix formed by stacking  $x^1, \ldots, x^n$  in the rows, *k* is the prior covariance function, and *k* and *K* are vector and matrix valued functions obtained from *k* by row-wise evaluation. Note that  $k(x, X^{1:n})$ is a row vector while  $k(X^{1:n}, x)$  is a column vector. The inversion  $(K(X^{1:n}, X^{1:n}) + \sigma^2 I)^{-1}$  is potentially costly, and does not depend on the test input *x*. It is cached by default in GPyTorch.

The other terms are computed as [\(Rasmussen & Williams, 2006,](#page-21-9) equations 2.24 and 2.38)

$$
\mu^{n}(\boldsymbol{x}') = \mu(\boldsymbol{x}') + k(\boldsymbol{x}', \mathbf{X}^{1:n}) \big( \mathbf{K}(\mathbf{X}^{1:n}, \mathbf{X}^{1:n}) + \sigma^{2} \mathbf{I} \big)^{-1} (\boldsymbol{v}^{1:n} - \mu(\mathbf{X}^{1:n})), \tag{35}
$$

$$
k^{n}(\mathbf{x}', \mathbf{x}) = k(\mathbf{x}', \mathbf{x}) - k(\mathbf{x}', \mathbf{X}^{1:n})\big(\mathbf{K}(\mathbf{X}^{1:n}, \mathbf{X}^{1:n}) + \sigma^{2}\mathbf{I}\big)^{-1}k(\mathbf{X}^{1:n}, \mathbf{x}).
$$
\n(36)

Here,  $\mu$  is the prior mean,  $\mu$  is the vector-valued function obtained from  $\mu$  by row-wise evaluation, and  $v^{1:n}$  is the vector of the first *n* noisy observations of *f*. As already mentioned, the inversion  $(K(X^{1:n}, X^{1:n})+\sigma^2 I)^{-1}$ does not depend on  $x$  and so should be cached. In fact, for the computation of  $\mu^n(x')$ , the whole product  $(K(X^{1:n}, X^{1:n}) + \sigma^2 I)^{-1}(v^{1:n} - \mu(X^{1:n}))$  is cached.

Further, the cross-covariances  $k(x', X^{1:n})$  also do not depend on  $x$  and are computed for many  $x'$ . Repeating this computation every time the query location  $x$  is updated is costly and wasteful. Writing  $X'$  for the matrix of a discretization points  $x' \in \mathbb{X}_{\text{disc}}$ , we may cache the matrix  $K(X', X^{1:n})$  during the optimization of  $\hat{\alpha}^n_{\text{KG}}(\boldsymbol{x})$ . Due to the design of the API, this is not done by default in GPyTorch.

In two-stage problems modelled by a GP  $f : \tilde{\mathbb{X}} \to \mathbb{R}$  with  $\tilde{\mathbb{X}} = \mathbb{X} \times \mathbb{Y} \times \mathbb{U}$ , the quantities to be cached are simply

$$
\left(\mathbf{K}(\tilde{\mathbf{X}}^{1:n}, \tilde{\mathbf{X}}^{1:n}) + \sigma^2 \mathbf{I}\right)^{-1},\tag{37a}
$$

$$
\left(\mathbf{K}(\tilde{\mathbf{X}}^{1:n}, \tilde{\mathbf{X}}^{1:n}) + \sigma^2 \mathbf{I}\right)^{-1} (\boldsymbol{v}^{1:n} - \boldsymbol{\mu}(\tilde{\mathbf{X}}^{1:n})),\tag{37b}
$$

$$
\mathbf{K}(\tilde{\mathbf{X}}', \tilde{\mathbf{X}}^{1:n}).
$$
\n(37c)

In the experiments in this paper, these quantities were cached in the implementation of the joint and alternating knowledge gradient acquisition functions.

# <span id="page-34-0"></span>**C Optimization of the acquisition functions using multi-start L-BFGS-B**

The acquisition functions for joint, alternating and two-step KG in Equations [\(12\)](#page-7-3), [\(15c\)](#page-9-1), [\(17\)](#page-10-1) and [\(19\)](#page-11-0) are optimized using multi-start L-BFGS using the heuristics implemented in the function optimize\_acqf in BoTorch [\(Balandat et al., 2020\)](#page-18-9). The function is called with nonnegative=True since knowledge gradient is non-negative (Proposition [A.4\)](#page-25-0).

In the following description of the BoTorch implementation, we use  $\tilde{\mathbb{X}} = \mathbb{X} \times \mathbb{Y} \times \mathbb{U}$  for the search space, which is appropriate for the joint and alternating KG. For two-step KG, the reader should mentally replace this with  $\mathbb{Y} \times \mathbb{U}$  or  $\mathbb{X} \times \mathbb{U}$  for the first and second steps respectively. We simply write  $\alpha(\cdot)$  for the acquisition function, dropping the superscript *n* so that the number of samples collected so far is implicit.

The start points for L-BFGS are generated by first evaluating the acquisition function at 256 locations in  $\tilde{X}_{raw} \subset \tilde{X}$  determined by a scrambled Sobol' sequence. These are referred to as 'raw samples'. The raw samples are subsampled to those at least  $0.01\%$  of the maximum,  $\alpha_{\text{max}} = \max_{\tilde{\bm{x}} \in \tilde{\mathbb{X}}_{\text{raw}}} \alpha(\tilde{\bm{x}})$ , to remove values close to zero. This gives,  $\tilde{\mathbb{X}}_{\text{raw},\gg 0} = {\{\tilde{x} \in \tilde{\mathbb{X}}_{\text{raw}} : \alpha(\tilde{x}) > 10^{-4} \alpha_{\text{max}}\}}$ . Finally, 10 restart locations are chosen from  $\tilde{\mathbb{X}}_{\text{raw},\gg0}$  using Boltzmann sampling. That is, a subsample is taken independently, without replacement using probabilities

$$
\forall \, \tilde{\bm{x}} \in \tilde{\mathbb{X}}_{\text{raw}, \gg 0} \quad p(\tilde{\bm{x}}) \propto e^{\alpha(\tilde{\bm{x}})/\alpha_{\text{max}}}.
$$

If the largest raw sample is not in the subsample then the last restart is replaced by this value. If  $\tilde{\mathbb{X}}_{\text{raw},\gg 0}$ does not contain at least 10 values, then the threshold of 0.01% is repeatedly reduced by a factor of 10 until it does.

Table [1](#page-35-1) summarizes the important parameters.

Parameter	Value
Number of restarts	10
Number of raw samples	256
Max number of L-BFGS-B iterations	200

<span id="page-35-1"></span>Table 1: Parameters for optimization of the knowledge gradient acquisition functions.

# <span id="page-35-0"></span>**D Optimization for the final recommendation**

Knowledge gradient acquisition functions are one-step Bayes-optimal when the final recommendation is given by the maximum of the posterior mean. For the joint and alternating knowledge gradient, this is given by Equation [\(10\)](#page-7-0). The optimization is done in two stages. First, the optimal fixed design,  $\hat{x}^{*n}$ , is chosen to maximize Equation [\(13\)](#page-7-4) using multi-start L-BFGS. Then, the optimal control policy,  $\hat{\boldsymbol{g}}^{*n}$ , is optimized for each *u* of interest using single-start L-BFGS. This section explains in detail how these optimizations are performed.

#### <span id="page-35-2"></span>**D.1 One-shot optimization of fixed design via multi-start L-BFGS-B**

The optimal fixed design,  $\hat{x}^{*n} \in \mathbb{X}$ , is found by rewriting Equation [\(13\)](#page-7-4) as

$$
\hat{\boldsymbol{x}}^{*n} \in \arg \max_{\boldsymbol{x} \in \mathbb{X}} \sum_{\boldsymbol{u} \in \mathbb{U}_{\mathrm{MC,rec}}} \max_{\boldsymbol{y} \in \mathbb{Y}} \mu^n(\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{u}) = \arg \max_{\substack{\boldsymbol{x} \in \mathbb{X} \\ \boldsymbol{y}^1, \dots, \boldsymbol{y}^{N_{u,rec}} \in \mathbb{Y}}} \sum_{i=1}^{N_{u,rec}} \mu^n(\boldsymbol{x}, \boldsymbol{y}^i, \boldsymbol{u}^i),
$$
(38)

where we have enumerated  $\mathbb{U}_{\text{MC,rec}} = {\mathbf{u}^1, \dots, \mathbf{u}^{N_{u,rec}}}$ .

This is optimized as one large  $d_x d_y^{N_{u,\text{rec}}}$ -dimensional problem, which we term a 'one-shot' optimization after the one-shot knowledge gradient [Balandat et al.](#page-18-9) [\(2020\)](#page-18-9). Here  $d_x$  and  $d_y$  are the dimensions of  $\mathbb{X} \subset \mathbb{R}^{d_x}$ and  $\mathbb{Y} \subset \mathbb{R}^{d_y}$ , respectively. It is optimized using multi-start L-BFGS-B with 10 restarts, as implemented in optimize\_acqf in BoTorch. A batch\_limit of 4 is used, meaning up to 4 restarts are grouped in a single  $4d_x d_y^{N_{u,rec}}$  optimization.

Care must be taken over the choice of the starting point for each of the 10 restarts. Simply scattering a large number of points over  $\mathbb{X} \times \mathbb{Y}^{N_{u,\text{rec}}}$  using a Sobol' sequence will lead the algorithm to converge to a local rather than global minimum. Indeed, it is highly unlikely that the starts will be well spread over Y for all of the  $N_{u,rec}$  realizations of **u**. Instead, we take Sobol' samples  $X_{raw} \subset X$  and  $Y_{raw} \subset Y$  of sizes  $N_{raw,x}$ and *N*raw*,y*, respectively, and combine them in a Cartesian fashion. Finally, Boltzmann sampling is used to select promising initial values for the 10 restarts. Explicitly, the steps are

- 1. Take Sobol' samples  $\mathbb{X}_{\text{raw}} \subset \mathbb{X}$  and  $\mathbb{Y}_{\text{raw}} \subset \mathbb{Y}$  of sizes  $N_{\text{raw},x}$  and  $N_{\text{raw},y}$ , respectively;
- 2. For each pair  $(\boldsymbol{x}, \boldsymbol{u}) \in \mathbb{X} \times \mathbb{U}_{MC,rec}$ , find the best  $\boldsymbol{y} \in \mathbb{Y}_{raw}$ ,

$$
\boldsymbol{y}(\boldsymbol{x},\boldsymbol{u})\in\argmax_{\boldsymbol{y}\in\mathbb{Y}_{\text{raw}}}\mu^n(\boldsymbol{x},\boldsymbol{y}(\boldsymbol{x},\boldsymbol{u}),\boldsymbol{u});
$$

3. Assign a score to each  $x \in \mathbb{X}_{\text{raw}}$  as

$$
s(\boldsymbol{x}) = \frac{1}{N_u} \sum_{\boldsymbol{u} \in \mathbb{U}_{\mathrm{MC,rec}}} \mu^n(\boldsymbol{x}, \boldsymbol{y}(\boldsymbol{x}, \boldsymbol{u}), \boldsymbol{u});
$$

4. Use Boltzmann sampling to randomly choose 10 initial locations from Xraw from the restarts without replacement, with independent probabilities

$$
\forall \mathbf{x} \in \mathbb{X}_{\text{raw}} \quad p(\mathbf{x}) \propto e^{z(\mathbf{x})} \qquad \text{where} \qquad \forall \mathbf{x} \in \mathbb{X}_{\text{raw}} \quad z(\mathbf{x}) = \frac{s(\mathbf{x}) - \overline{s}}{\sigma_s},
$$

where  $\bar{s}$  and  $\sigma_s$  are the mean and sample standard deviation of the  $s(\bm{x})$ . If the  $\bm{x} \in \mathbb{X}_{\text{raw}}$  with the highest score was not selected, then the last restart is replaced by this value.

The number of raw samples used depends on the dimension of the problem. In the test problems with  $d_x = 1, 2$ , we used  $N_{\text{raw},x} = 32$ , while when  $d_x = 4$  we used  $N_{\text{raw},x} = 128$ . Similarly, we used  $N_{\text{raw},y} = 32$ when  $d_y = 1, 2$  and  $N_{\text{raw},y} = 128$  when  $d_y = 4$ . We use an init\_batch\_limit of  $2^{17}$ , meaning we will evaluate  $\mu^n(\bm{x}, \bm{y}, \bm{u})$  for all  $(\bm{x}, \bm{y}, \bm{u}) \in \mathbb{X}_{\text{raw}} \times \mathbb{Y}_{\text{raw}} \times \mathbb{U}_{\text{MC,rec}}$  in batches of  $2^{17}$  points, which is significantly faster than using a for loop in python. In our experiments with the largest dimensions, we have  $|X_{raw} \times V_{raw} \times U_{MC,raw}|$  $32 \times 128 \times 128 = 2^{19}$ , so this equates to four batches. Limits on memory prevent us from increasing the init\_batch\_limit arbitrarily high. Table [2](#page-36-0) summarizes the key parameters for the optimization of  $\hat{x}^{*n}$ .

<span id="page-36-0"></span>

Table 2: Parameters for optimization of the recommended fixed design,  $\hat{x}^{*n}$ .

#### **D.2 Single-start L-BFGS-B for optimization of control policy**

Once  $\hat{\mathbf{x}}^{*n}$  has been found, we must optimize to find  $\hat{\mathbf{g}}^{*n}(\mathbf{u}) \in \mathbb{Y}$  for the  $\mathbf{u} \in \mathbb{U}$  of interest. For example, when computing the simple regret from Equation [\(21\)](#page-13-2), we wish to compute  $\hat{\bm{g}}^{*n}(\bm{u}^j)$  for a sample  $\bm{u}^1,\ldots,\bm{u}^{N_u}$ of the environmental variable  $\bf{u}$ , independent of the one used to optimize  $\hat{\bf{x}}^{*n}$ . Empirically, we found that a single start L-BFGS-B is sufficient for this problem. Again, we use optimize\_acqf from BoTorch, with  $N_{\text{raw},y} = 32$  or 128 raw samples depending on the problem dimension, as in Appendix [D.1.](#page-35-2) The best of the raw samples is used as the initial point for the L-BFGS-B. Optimizations for the different *u* are run separately.

<span id="page-36-1"></span>

Parameter	Value
Number of restarts	
Number of raw samples	32 or 128 (dimension dependent)
Batch limit	
Batch limit for raw samples	$> N_{\text{raw},y}$
Max number of L-BFGS-B iterations	200

Table 3: Parameters for optimization of the recommended control policy,  $\hat{g}^{*n}(\boldsymbol{u})$ .

### **E Further Experimental Details**

In this appendix we give details and parameters used in the experiments necessary for reproducing the results.

#### **E.1 Experimental parameters**

Table [4](#page-37-1) summarizes the parameters used for the optimization of the acquisition function and estimation of the the (average) simple regret in the empirical studies. These are in addition to the parameters which have already been specified in Tables [1](#page-35-1) to [3.](#page-36-1)

Table [5](#page-37-2) summarizes the dimensions and length scales used for the different GP sampled synthetic problems. All GP generated test problems used a Matérn-5/2 kernel with an output scale of 10, defined on the unit

<span id="page-37-1"></span>

Table 4: Parameters used for the optimization of the acquisition function and estimation of the simple regret in the empirical studies.

hypercube,  $[0,1]^d$ . They were generated with a random Fourier feature approximation with 1024 features, as described in [\(Rahimi & Recht, 2007\)](#page-21-13) and implemented in BoTorch [\(Balandat et al., 2020\)](#page-18-9).

For the problems with a combined dimension of  $d = d_x + d_y + d_u = 6$  an initial design of  $n_0 = 50$  points was used, with a total budget of  $n_{\text{tot}} = 400$  evaluations. The two-step algorithms used  $n_1 = n_2 = 50$  points for the initial design of the first and second phases and had a total evaluation budget of  $n_{\text{tot,1}} = n_{\text{tot,2}} = 200$ for each phase. These problems were used for the examining the effects of dimension and observation noise, and used a length scale of 0*.*4 in all dimensions.

The problems used to examine the effect of length scale had a combined dimension of  $d = d_x + d_y + d_u = 3$ . For these, an initial design of  $n_0 = 10$  points was used, with a total budget of  $n_{\text{tot}} = 100$  evaluations. The two-step algorithms used  $n_1 = n_2 = 10$  points for the initial design and had a total evaluation budget of  $n_{\text{tot},1} = n_{\text{tot},2} = 50$  for each step.

<span id="page-37-2"></span>The optical table test problem used an initial design of  $n_0 = 6$  points and a total budget of  $n_{\text{tot}} = 100$ evaluations. The two-step algorithms used  $n_1 = n_2 = 6$  points in the initial design and had a total evaluation budget of  $n_{\text{tot},1} = n_{\text{tot},2} = 50$  for each step.

Table 5: Dimensions and length scales used in the GP sampled test problems in the empirical studies. All problems were generated with a Matérn-5/2 kernel with an output scale of 10.

#### <span id="page-37-0"></span>**E.2 Optical table test problem**

The optical table system described in Section [4.3](#page-13-1) obeys the following differential equation

$$
m\ddot{y} + c\dot{y} + 4ky = c\dot{y}_f + 4ky_f + 4k\ell - gm \tag{39}
$$

where Table [6](#page-38-1) summarizes the different constants and variables used here. We assume that the floor is undergoing simple harmonic motion

$$
y_f = A\cos(\omega t + \phi_f). \tag{40}
$$

Then the solution to the differential equation is the superposition of a steady state vibration, a constant offset and a transient response which depends on the initial conditions and decays over time,

$$
y = \underbrace{B \cos(\omega t + \phi)}_{\text{steady state vibration}} + \underbrace{\ell - \frac{gm}{2k}}_{\text{constant offset}} + \underbrace{y_c}_{\text{transient}}.
$$
 (41)

The transient part is given by

$$
y_c = \begin{cases} C_1 e^{\alpha_1 t} + C_2 e^{\alpha_2 t} & \text{if } c^2 > 8km \text{ (overdamped)},\\ (C_1 + C_2 t)e^{-ct/2m} & \text{if } c^2 = 8km \text{ (critically damped)},\\ C e^{-ct/2m} \cos(\beta t + \phi_c) & \text{if } c^2 < 8km \text{ (underdamped)}. \end{cases}
$$
(42)

Here  $\alpha_1, \alpha_2 = \frac{-c \pm \sqrt{c^2 - 8km}}{2m}$  are the roots of the characteristic equation and  $\beta = \frac{\sqrt{8km-c^2}}{2m}$  is the imaginary part of  $\alpha_1$  when it has one. The constants  $C_1$ ,  $C_2$ ,  $C$  and  $\phi_c$  are arbitrary.

Thus, the amplitude ratio for the steady state solution is

$$
\frac{B}{A} = \sqrt{\frac{16k^2 + c^2\omega^2}{(4k - m\omega^2)^2 + c^2\omega^2}}.
$$
\n(43)

Table 6: Constants and variables used in the model of the optical table.

#### <span id="page-38-0"></span>**E.3 Fitting the GP Surrogate Model**

The Gaussian process  $f \sim \mathcal{GP}(\mu, k)$  used to model the unknown, expensive function  $h : \mathbb{X} \times \mathbb{Y} \times \mathbb{U} \to \mathbb{R}$ (or a restriction of *h* in the case of the two-step algorithms) uses a constant mean,  $\mu$ , and a Matérn-5/2 kernel, *k*, with separate length scales for each input dimension (known as *automatic relevance determination*, [\(Williams & Rasmussen, 1995\)](#page-22-13)). The constant mean, length scales, output scale and standard deviation of the observation noise of the GP are collectively referred to as the hyperparameters of the GP.

The hyperparameters are fitted to the observations using maximum a posterior (MAP) estimation. Gamma prior distributions are placed on the length scales, output scale and noise standard deviation, while the mean uses an improper, uninformative prior equivalent to a Gaussian with infinite variance.

The hyperparameters are updated at the start of each iteration, to incorporate the new observations. The first time the GP is fitted, the initial observations are normalized to have zero mean and unit variance and MAP estimates are generated for all hyperparameters to fit the normalized observations. On future iterations, the data is renormalized and the constant mean from the initial fit is updated to the new normalization.

New MAP estimates for all hyperparameters except the constant mean are found. When using the GP in the acquisition function or when making recommendations, the GP is untransformed. That is, if *f*<sub>norm</sub> ∼  $\mathcal{GP}(\mu_{\text{norm}}, k_{\text{norm}})$  is the GP fitted to the normalized data, then  $f = a + bf_{\text{norm}}$  is the GP referred to in the main text, where *a* and *b* are the mean and sample standard deviation of the observations.

On problems where the observation noise is known to be zero, the observation noise variance,  $\sigma^2$ , is fixed at 10−<sup>8</sup> instead of being estimated from the observations. In our experiments, the observation noise variance is only fitted for the experiment in Figure [4.](#page-15-1)

The Gamma distributions  $Gamma(\alpha, \beta)$  in Table [7](#page-39-0) are parameterized in terms of a concentration parameter, *α*, and rate parameter, *β*, and have density function

$$
p(z) = \frac{\beta^{\alpha}}{\Gamma(\alpha)} z^{\alpha - 1} e^{-\beta z}.
$$
\n(44)

<span id="page-39-0"></span>

Table 7: Prior distributions and fitting notes on the GP hyperparameters. Gamma distributions, Gamma $(\alpha, \beta)$ , are specified in terms of their concentration,  $\alpha$ , and rate,  $\beta$ , parameters.
