(Dated: November 19, 2024)

We study the three-body Fermi liquid effects in the $SU(N)$ Anderson impurity model in the strong interaction limit where the occupation number N_d of the impurity levels varies over the range of $0 < N_d < 1$. The three-body correlation of impurity electrons contributes to the next-toleading order terms of transport coefficients at low energies when the electron-hole symmetry, the time-reversal symmetries, or both are broken by external fields or potentials. Using the numerical renormalization group approach, we calculate the differential conductance and the nonlinear current noise through quantum dots, as well as the thermal conductivity of both quantum dots and magnetic alloys. Specifically, we focus on the $SU(2)$ and $SU(4)$ cases and demonstrate how the three-body contributions evolve in the limit of $U \to \infty$, across the 1/N-filling Kondo regime and the valence fluctuation regime. Our results clarify how the three-body correlation affects low-energy transport, with a crucial dependence on the occupation number N_d . We also show that the threebody correlation strongly couples with asymmetries in the tunnel couplings between quantum dots and reservoirs; in particular it significantly affects the nonlinear current through the quarter-filling Kondo state for $N = 4$.

I. INTRODUCTION

The Kondo effect is an intriguing quantum phenomenon [\[1,](#page-15-0) [2\]](#page-15-1) that occurs in dilute magnetic alloys (MAs), quantum dots (QDs), and various exotic systems, such as ultracold atomic gases [\[3\]](#page-15-2) and quark matter [\[4\]](#page-15-3). In these Kondo systems, localized impurity spins are screened by surrounding conduction electrons at low energies, leading to a highly correlated singlet ground state. In the 1970s, it was confirmed that the ground state and low-lying energy excitations, obtained with the high-accuracy numerical renormalization group (NRG) [\[5–](#page-15-4)[7\]](#page-15-5), can be described by an effective zero-dimensional field theory, commonly known as local Fermi liquid theory [\[8](#page-15-6)[–12\]](#page-15-7).

The low-energy properties of Kondo systems realized in quantum dots have been studied intensively through highly sensitive measurements [\[13–](#page-15-8)[26\]](#page-16-0). Simultaneously, theories to deduce the universal Fermi liquid behavior from experiments have been developed, specifically for electrical currents [\[27–](#page-16-1)[35\]](#page-16-2), shot noise [\[36–](#page-16-3)[40\]](#page-16-4), and thermal conductivity [\[41–](#page-16-5)[43\]](#page-16-6). Furthermore, recent developments have revealed that three-body correlations between impurity electrons play an essential role in Fermiliquid transport at low but finite temperatures T or finite bias voltages eV [\[44](#page-16-7)[–50\]](#page-16-8).

Three-body correlations emerge when the electron-hole symmetry, the time-reversal symmetry, or both are broken by an internal potential or external field, and evolve as the impurity level ϵ_d shifts toward or away from the Fermi level E_F of conduction bands. These correlations affect the next-to-leading order terms in both the linear and nonlinear responses of electrical and thermal currents

 $[51–58]$ $[51–58]$. The degeneracy N of impurity state also introduces interesting variations in three-body effects. The $SU(N)$ Kondo state for $N = 4$, consisting of the spin and orbital degrees of freedoms, has been realized in carbon nanotubes and other types of quantum dots [\[23,](#page-16-11) [59–](#page-16-12) [64\]](#page-16-13) and has investigated theoretically by a numerous authors [\[65–](#page-16-14)[74\]](#page-16-15). In particular, Mora et al. derived several Fermi-liquid relations for the three-body correlations in the $SU(N)$ Kondo model, which can be classified according to an integer N_d (= 1, 2, ..., $N-1$) that corresponds to the number of electrons at the impurity site [\[44,](#page-16-7) [45\]](#page-16-16).

Fermi liquid theory for three-body correlations has also been developed for the Anderson impurity model, in which the occupation number N_d can vary continuously in the range $0 < N_d < N$ [\[46–](#page-16-17)[50,](#page-16-8) [54](#page-16-18)[–58\]](#page-16-10). For multilevel impurities with $N \geq 4$, it has been shown that the contribution of three-body correlations is particularly pronounced in the Kondo states with the electron numbers $N_d \simeq 1$ and $N-1$, and that this contribution increases with the Coulomb interaction U [\[57,](#page-16-19) [58\]](#page-16-10). Therefore, it is expected that three-body correlations are maximized in the strong interaction limit $U \to \infty$, which could provide a benchmark for their contributions. Low-energy properties at $U \rightarrow \infty$ have been studied for a long time, for instance with the NRG, while also taking additional intersite Coulomb interactions into account [\[75–](#page-16-20)[77\]](#page-16-21). However, to our knowledge, three body correlations have not yet been explored in this limit.

The purpose of this paper is to demonstrate the role of three-body correlations in the $SU(N)$ Anderson model in the strong interaction limit $U \rightarrow \infty$ over a wide range of the impurity level position ϵ_d , across the 1/Nfilling Kondo regime and the valence fluctuation regime

 $0 < N_d < 1$. To this end, we calculate the Fermi liquid parameters such as the phase shift δ_{σ} , the linear susceptibility $\chi_{\sigma\sigma'}$ and the three-body correlation function $\chi_{\sigma\sigma'\sigma''}^{[3]}$, using the NRG for $N=2$ and $N=4$. Here, σ labels the N impurity levels, with $\sigma = 1, 2, ..., N$. From these correlation functions, electrical and thermal currents through quantum dots or magnetic alloys can be deduced up to next-to-leading order at finite T and finite eV .

The three-body correlation function $\chi_{\sigma\sigma'\sigma''}^{[3]}$ has three independent components for the $SU(N)$ Anderson model of $N > 4$, which approach a single universal value in the $1/N$ -filling Kondo regime. However, as the occupation number N_d decreases from the 1/N-filling, the three independent components contribute distinctly to the transport coefficients, especially in the valence fluctuation regime. We also find that the order $|eV|^3$ term of the shot noise for $SU(4)$ quantum dots becomes positive definite throughout the entire range of ϵ_d in the limit of $U \rightarrow \infty$, in contrast to the case of finite interactions, where the order $|eV|^3$ term takes a negative value in the valence fluctuation regime for small U [\[58\]](#page-16-10). Additionally, we investigate the effects of tunneling and bias asymmetries on the nonlinear conductance through quantum dots at $U \rightarrow \infty$ [\[56,](#page-16-22) [57\]](#page-16-19), and demonstrate that the three-body correlations couple strongly to these asymmetries.

This paper is organized as follows. In Sec. [II,](#page-1-0) we introduce the Anderson impurity model for QDs and MAs, along with the Fermi liquid parameters that include three-body correlations. We also introduce the nonequilibrium steady-state current and current noise through QDs. Section [III](#page-2-0) is devoted to the formulation of thermoelectiric transport for QDs and MAs. Section [IV](#page-3-0) discusses the three-body correlations in $SU(N)$ case. In Sec. [V](#page-4-0) we discuss NRG results for the Fermi liquid parameters obtained in the $U \rightarrow \infty$ limit for SU(2) and SU(4) symmetric cases. In Sec. [VI,](#page-4-1) we discuss the behavior of the next-to-leading-order terms of the differential conductance dI/dV through QDs, and examine their dependence on the tunneling and bias asymmetries. Section [VII](#page-8-0) addresses the nonlinear current noise through QDs for $U \to \infty$. Sections [VIII](#page-9-0) and [IX](#page-10-0) describe thermoelectric transport of QDs and MAs, respectively. A summary is provided in Sec. [X.](#page-12-0) In the Appendix, we briefly describe Fermi liquid relations including the three-body correlations.

II. FORMULATION

A. Multilevel Anderson impurity model

We begin with an N-level Anderson impurity model connected to two non-interacting leads on the left (L) and right (R) :

$$
H = H_d + H_c + H_T,\t\t(2.1)
$$

$$
H_d = \sum_{\sigma=1}^{N} \epsilon_{d\sigma} n_{d\sigma} + \sum_{\sigma \neq \sigma'} \frac{U}{2} n_{d\sigma} n_{d\sigma'},
$$
 (2.2)

$$
H_c = \sum_{\nu=L,R} \sum_{\sigma=1}^{N} \int_{-D}^{D} d\epsilon \, c_{\epsilon\nu\sigma}^{\dagger} c_{\epsilon\nu\sigma} \,, \tag{2.3}
$$

$$
H_T = -\sum_{\nu=L,R} \sum_{\sigma=1}^{N} v_{\nu} \int_{-D}^{D} d\epsilon \sqrt{\rho_c} \left(c_{\epsilon\nu\sigma}^{\dagger} d_{\sigma} + \text{H.c.} \right), (2.4)
$$

Here, d_{σ}^{\dagger} for $\sigma = 1, 2, ..., N$, is the creation operator for an impurity electron with energy $\epsilon_{d\sigma}$, U represents the Coulomb interaction between two impurity electrons. The number operator of impurity electrons is given by $n_{d\sigma} \equiv d_{\sigma}^{\dagger} d_{\sigma}$. Additionally, $c_{\epsilon\nu\sigma}^{\dagger}$ is the creation operator for conduction electrons in the noninteracting lead on $\nu = L, R$, normalized such that $\{c_{\epsilon\nu\sigma}, c_{\epsilon'\nu'\sigma'}^{\dagger}\} = \delta(\epsilon - \epsilon')$ ϵ ′) δνν′δσσ′ . Charge transfer occurring between impurity level and conduction bands is described by H_T , where $\rho_c \equiv 1/(2D)$ and D is the half band width of conduction bands. The bare level width due to the tunnel coupling v_{ν} is given by $\Delta \equiv \Gamma_L + \Gamma_R$, with $\Gamma_{\nu} \equiv \pi \rho_c v_{\nu}^2$.

The current flowing through the impurity level σ satisfies the equation of continuity, given by

$$
\frac{\partial n_{d\sigma}}{\partial t} + \widehat{I}_{R,\sigma} - \widehat{I}_{L,\sigma} = 0.
$$
 (2.5)

Here, $I_{L,\sigma}$ represents the current flowing from the left lead to the impurity level, and $I_{R,\sigma}$ represents the current from the impurity level to the right lead:

$$
\widehat{I}_{L,\sigma} = -i v_L \left(\psi_{L\sigma}^{\dagger} d_{\sigma} - d_{\sigma}^{\dagger} \psi_{L\sigma} \right), \tag{2.6}
$$

$$
\widehat{I}_{R,\sigma} = + i v_R \left(\psi_{R\sigma}^{\dagger} d_{\sigma} - d_{\sigma}^{\dagger} \psi_{R\sigma} \right). \tag{2.7}
$$

B. Three-body correlation functions

The low-energy properties of the Anderson impurity can be described by Fermi liquid parameters, which include the occupation numbers $\langle n_{d\sigma} \rangle$, susceptibilities $\chi_{\sigma_1\sigma_2}$, and three-body correlation functions $\chi_{\sigma_1\sigma_2\sigma_3}^{[3]}$:

$$
\langle n_{d\sigma} \rangle = \frac{\partial \Omega}{\partial \epsilon_{d\sigma}},\tag{2.8}
$$

$$
\chi_{\sigma_1 \sigma_2} \equiv -\frac{\partial \Omega}{\partial \epsilon_{d\sigma_1} \partial \epsilon_{d\sigma_2}} = \int_0^\beta d\tau \, \langle \delta n_{d\sigma_1}(\tau) \, \delta n_{d\sigma_2} \rangle, \tag{2.9}
$$

$$
\chi_{\sigma_1 \sigma_2 \sigma_3}^{[3]} \equiv -\frac{\partial^3 \Omega}{\partial \epsilon_{d\sigma_1} \partial \epsilon_{d\sigma_2} \partial \epsilon_{d\sigma_3}}\n= -\int_0^\beta d\tau \int_0^\beta d\tau' \langle T_\tau \delta n_{d\sigma_1}(\tau) \delta n_{d\sigma_2}(\tau') \delta n_{d\sigma_3} \rangle.
$$
 (2.10)

Here, $\langle \mathcal{O} \rangle = \text{Tr} \left[e^{-\beta H} \mathcal{O} \right] / \text{Tr} e^{-\beta H}$ denotes the thermal average, $\Omega \equiv -\frac{1}{\beta} \ln[e^{-\beta H}]$ is the free energy, and $\beta = 1/T$ is the inverse temperature. Additionally, $\delta n_{d\sigma} \equiv n_{d\sigma} \langle n_{d\sigma} \rangle$, $\mathcal{O}(\tau) \equiv e^{\tau H} \mathcal{O} e^{-\tau H}$, and T_{τ} is the imaginary-time ordering operator. Specifically, the ground-state values of these correlation functions — namely, $\langle n_{d\sigma} \rangle$, $\chi_{\sigma_1 \sigma_2}$, and $\chi_{\sigma_1 \sigma_2 \sigma_3}^{[3]}$ at $T = 0$ — completely determine the lowenergy transport properties in the Fermi liquid regime, up to the next-to-leading order terms.

C. Nonequilibrium current through quantum dots

We consider a steady current I under a finite bias voltage V :

$$
I = \frac{e}{h} \sum_{\sigma=1}^{N} \int_{-\infty}^{\infty} d\omega \left[f_L(\omega) - f_R(\omega) \right] \mathcal{T}_\sigma(\omega), \qquad (2.11)
$$

$$
\mathcal{T}_{\sigma}(\omega) \equiv \frac{4\Gamma_L \Gamma_R}{\Gamma_L + \Gamma_R} \pi A_{\sigma}(\omega). \qquad (2.12)
$$

Here, the average $I = \sum_{\sigma} \langle I_{R,\sigma} \rangle_V = \sum_{\sigma} \langle I_{L,\sigma} \rangle_V$ is defined with respect to a nonequilibrium steady state, constructed at finite bias voltages eV and temperatures T , using the Keldysh formalism [\[29,](#page-16-23) [30,](#page-16-24) [78\]](#page-16-25). The Fermi distribution function for the conduction band in lead $\nu = L$ or R is given by $f_{\nu}(\omega) = \left[e^{\beta(\omega-\mu_{\nu})} + 1\right]^{-1}$. We assume that the chemical potentials of the left and right leads are shifted from the Fermi level at equilibrium ($E_F \equiv 0$) such that $\mu_L = E_F + \alpha_L eV$ and $\mu_R = E_F - \alpha_R eV$, where α_L and α_R are parameters that satisfy the condition $\alpha_L + \alpha_R = 1$, ensuring $\mu_L - \mu_R \equiv eV$. Thus, asymmetries in the applied bias voltage and the tunnel couplings can be described by the following parameters:

$$
\alpha_{\text{dif}} \equiv \frac{\mu_L + \mu_R - 2E_F}{\mu_L - \mu_R} = \alpha_L - \alpha_R, \qquad (2.13)
$$

$$
\gamma_{\text{dif}} \equiv \frac{\Gamma_L - \Gamma_R}{\Gamma_L + \Gamma_R} \,. \tag{2.14}
$$

The spectral function $A_{\sigma}(\omega)$ on the right-hand side of Eq. [\(2.12\)](#page-2-1) is defined as the imaginary part of retarded Green's function:

$$
G_{\sigma}^{r}(\omega) = -i \int_{0}^{\infty} dt \, e^{i(\omega + i0^{+})t} \left\langle \left\{ d_{\sigma}(t), d_{\sigma}^{\dagger} \right\} \right\rangle_{V} . \tag{2.15}
$$

$$
A_{\sigma}(\omega) = -\frac{1}{\pi} \operatorname{Im} G_{\sigma}^{r}(\omega) . \qquad (2.16)
$$

The behavior of the Green's function at small ω , T, and eV determines the low-energy Fermi liquid properties, which are summarized in Appendix [A.](#page-13-0)

We also consider the current noise $S_{\text{noise}}^{\text{QD}}$, defined as the correlation function for fluctuations of a symmetrized current $\delta I = I - \langle I \rangle_V$ [\[36,](#page-16-3) [44,](#page-16-7) [46,](#page-16-17) [54,](#page-16-18) [55\]](#page-16-26):

σ

$$
S_{\text{noise}}^{\text{QD}} \equiv e^2 \int_{-\infty}^{\infty} dt \left\langle \delta \hat{I}(t) \delta \hat{I}(0) + \delta \hat{I}(0) \delta \hat{I}(t) \right\rangle_V, (2.17)
$$

$$
\hat{I} \equiv \sum \frac{\Gamma_R \hat{I}_{L,\sigma} + \Gamma_L \hat{I}_{R,\sigma}}{\Gamma_L + \Gamma_R}.
$$

Specifically, we calculate the terms up to order $|eV|^3$ for nonlinear noise, based on expansion formulas obtained in Ref. [55,](#page-16-26) taking into account all contributions from vertex corrections in the Keldysh formalism.

III. THERMOELECTRIC TRANSPORT **COEFFICIENTS**

We also consider the thermoelectric transport through multilevel quantum dots and magnetic alloys in the linear-response regime, the low-energy behaviors of which can be deduced from the asymptotic form of the spectral function $A_{\sigma}(\omega)$. Specifically, we focus on the threebody Fermi liquid corrections that emerge in the nextto-leading order terms of the electrical and heat currents, as discussed later in Secs. [VIII](#page-9-0) and [IX.](#page-10-0) Here, we briefly describe the basic formulations.

When the temperature difference δT is applied between the two leads such that $\delta T = T_L - T_R$, a heat current $I_Q = \kappa \delta T$ flows from the high-temperature side toward the low-temperature side, through quantum dots, or magnetic alloys. The thermal conductivity κ is defined as the linear-response coefficient of I_Q .

A. Thermoelectric coefficients for quantum dots

The linear conductance g, thermopower \mathcal{S}_{QD} and thermal conductance κ_{OD} of a quantum dot can be expressed in the form [\[41,](#page-16-5) [52,](#page-16-27) [79](#page-16-28)[–81\]](#page-16-29):

$$
g \equiv \left. \frac{dI}{dV} \right|_{eV=0} = \left. \frac{e^2}{h} \sum_{\sigma} \mathcal{L}_{0,\sigma}^{\text{QD}}, \right. \tag{3.1}
$$

$$
S_{\rm QD} = \frac{-1}{|e|T} \frac{\sum_{\sigma} \mathcal{L}_{1,\sigma}^{\rm QD}}{\sum_{\sigma} \mathcal{L}_{0,\sigma}^{\rm QD}} ,
$$
\n(3.2)

$$
\kappa_{\rm QD} = \frac{1}{hT} \left[\sum_{\sigma} \mathcal{L}_{2,\sigma}^{\rm QD} - \frac{\left(\sum_{\sigma} \mathcal{L}_{1,\sigma}^{\rm QD} \right)^2}{\sum_{\sigma} \mathcal{L}_{0,\sigma}^{\rm QD}} \right].
$$
 (3.3)

Here, $\mathcal{L}_{n,\sigma}^{\text{QD}}$ for $n = 0, 1$, and 2 is defined at $eV = 0$ with respect to the thermal equilibrium, as

$$
\mathcal{L}_{n,\sigma}^{\text{QD}} = \int_{-\infty}^{\infty} d\omega \,\omega^n \,\mathcal{T}_{\sigma}(\omega) \left(-\frac{\partial f(\omega)}{\partial \omega} \right),\tag{3.4}
$$

were $\mathcal{T}_{\sigma}(\omega)$ is the transmission probability defined in Eq. $(2.12).$ $(2.12).$

B. Thermoelectric coefficients for magnetic alloys

Within the linear response theory, the electrical resistivity $\varrho_{\text{MA}} = 1/\sigma_{\text{MA}}$, the thermopower \mathcal{S}_{MA} , and the thermal conductivity κ_{MA} for magnetic alloys are given by [\[42\]](#page-16-30):

$$
\sigma_{\text{MA}} = \sigma_{\text{MA}}^{\text{unit}} \frac{1}{N} \sum_{\sigma} \mathcal{L}_{0,\sigma}^{\text{MA}}, \qquad (3.5)
$$

$$
\mathcal{S}_{\text{MA}} = \frac{-1}{|e|T} \frac{\sum_{\sigma} \mathcal{L}_{1,\sigma}^{\text{MA}}}{\sum_{\sigma} \mathcal{L}_{0,\sigma}^{\text{MA}}},\tag{3.6}
$$

$$
\kappa_{\text{MA}} = \frac{\sigma_{\text{MA}}^{\text{unit}}}{e^2 T} \frac{1}{N} \left[\sum_{\sigma} \mathcal{L}_{2,\sigma}^{\text{MA}} - \frac{\left(\sum_{\sigma} \mathcal{L}_{1,\sigma}^{\text{MA}} \right)^2}{\sum_{\sigma} \mathcal{L}_{0,\sigma}^{\text{MA}}} \right]. \quad (3.7)
$$

For magnetic alloys, the response functions $\mathcal{L}_{n,\sigma}^{\text{MA}}$ for $n =$ 0, 1 and 2 are determined by the inverse spectral function $1/A_{\sigma}(\omega)$ at $eV=0$:

$$
\mathcal{L}_{n,\sigma}^{\text{MA}} = \int_{-\infty}^{\infty} d\omega \, \frac{\omega^n}{\pi \Delta A_{\sigma}(\omega)} \left(-\frac{\partial f(\omega)}{\partial \omega} \right). \tag{3.8}
$$

Equation [\(3.5\)](#page-3-1) defines the electrical conductivity relative to its unitary-limit value $\sigma_{\text{MA}}^{\text{unit}}$. In the limit $T \to 0$, the electrical and thermal conductivities of the Anderson impurity satisfy the Wiedemann-Franz law (see Sec. [IX\)](#page-10-0):

$$
\lim_{T \to 0} \frac{\kappa_{\text{MA}}}{T \sigma_{\text{MA}}} = \frac{\pi^2}{3 e^2}.
$$
\n(3.9)

IV. THREE-BODY CORRELATIONS FOR $\text{SU}(N)$ ANDERSON IMPURITY

The Hamiltonian H, defined in Eqs. (2.1) – (2.4) , exhibits $SU(N)$ symmetry when the impurity levels are degenerate, i.e., $\epsilon_{d\sigma} \equiv \epsilon_d$ for all σ . At zero temperature $T = 0$, the occupation number of the impurity electron is determined by the phase shift δ_{σ} through the Friedel sum rule $\langle n_{d\sigma} \rangle = \delta_{\sigma}/\pi$, which plays an central role in the ground-state property. In particular, in the $SU(N)$ symmetric case, the total number of impurity electrons is given by

$$
N_d \equiv \sum_{\sigma=1}^{N} \langle n_{d\sigma} \rangle \xrightarrow{\text{SU}(N)} \frac{N}{\pi} \delta. \tag{4.1}
$$

Correspondingly, the linear susceptibilities have two linearly independent components: the diagonal one $\chi_{\sigma\sigma}$ and the off-diagonal one $\chi_{\sigma\sigma'}$ for $\sigma \neq \sigma'$. The diagonal component determines a characteristic energy scale T^* of the $SU(N)$ Fermi liquid, which allows the T-linear specific heat $\mathcal{C}_{\text{imp}}^{\text{heat}}$ of impurity electrons to be expressed in the following form [\[9,](#page-15-9) [11,](#page-15-10) [12\]](#page-15-7):

$$
\mathcal{C}_{\rm imp}^{\rm heat} = \frac{N\pi^2}{12} \frac{T}{T^*}, \qquad T^* \equiv \frac{1}{4\chi_{\sigma\sigma}}. \qquad (4.2)
$$

Note that the diagonal susceptibility can be expressed as $\chi_{\sigma\sigma} = \rho_{d\sigma}/z$, where the density of state of impurity electrons is given by $\rho_{d\sigma} = \sin^2 \delta / (\pi \Delta)$ and z is the wavefunction renormalization factor defined in Appendix [A.](#page-13-0) The off-diagonal susceptibility determines the Wilson ratio R , or the rescaled one K , which is bounded in the range $0 \leq K \leq 1$:

$$
R \equiv 1 - \frac{\chi_{\sigma\sigma'}}{\chi_{\sigma\sigma}}, \qquad \tilde{K} \equiv (N-1)(R-1). \quad (4.3)
$$

We also introduce dimensionless parameters for threebody correlations, which have three independent components for $N \geq 3$ in SU(N) symmetric case:

$$
\Theta_{\rm I} = \frac{\sin 2\delta}{2\pi} \frac{\chi_{\sigma\sigma}^{[3]}}{\chi_{\sigma\sigma}^{2}} , \qquad \widetilde{\Theta}_{\rm II} = \frac{\sin 2\delta}{2\pi} \frac{\widetilde{\chi}_{\sigma\sigma'\sigma'}^{[3]}}{\chi_{\sigma\sigma}^{2}} , \quad (4.4)
$$

$$
\widetilde{\Theta}_{\mathbb{II}} = \frac{\sin 2\delta}{2\pi} \frac{\widetilde{\chi}_{\sigma\sigma'\sigma''}^{[3]}}{\chi_{\sigma\sigma}^2}, \qquad \sigma \neq \sigma' \neq \sigma'' \neq \sigma. \tag{4.5}
$$

For the later two components, we have introduced rescaled correlation functions $\widetilde{\chi}_{\sigma\sigma'\sigma'}^{[3]}$ and $\widetilde{\chi}_{\sigma\sigma'\sigma''}^{[3]}$ defined as follows:

$$
\tilde{\chi}^{[3]}_{\sigma\sigma'\sigma'} \equiv (N-1)\,\chi^{[3]}_{\sigma\sigma'\sigma'},\tag{4.6}
$$

$$
\widetilde{\chi}_{\sigma\sigma'\sigma''}^{[3]} \equiv \frac{(N-1)(N-2)}{2} \chi_{\sigma\sigma'\sigma''}^{[3]}.
$$
 (4.7)

In this work, we have calculated these three-body correlations as well as the two-body correlations $\chi_{\sigma\sigma'}$ [\[40,](#page-16-4) [54,](#page-16-18) [58,](#page-16-10) [82](#page-17-0)[–85\]](#page-17-1), using the NRG approach, employing the following relations [see Appendix [B](#page-15-11) for details]:

$$
\chi_{\sigma\sigma\sigma}^{[3]} = \frac{1}{N} \frac{\partial \chi_{\sigma\sigma}}{\partial \epsilon_d} - \frac{N-1}{N} \chi_B^{[3]},\tag{4.8}
$$

$$
\tilde{\chi}^{[3]}_{\sigma\sigma'\sigma'} = \frac{N-1}{N} \frac{\partial \chi_{\sigma\sigma}}{\partial \epsilon_d} + \frac{N-1}{N} \chi^{[3]}_B, \qquad (4.9)
$$

$$
\widetilde{\chi}_{\sigma\sigma'\sigma''}^{[3]} = -\frac{N-1}{N} \frac{\partial \chi_{\sigma\sigma}}{\partial \epsilon_d} + \frac{N-1}{2} \frac{\partial \chi_{\sigma\sigma'}}{\partial \epsilon_d} - \frac{N-1}{N} \chi_B^{[3]}.
$$
\n(4.10)

Here, $\chi_{\rm B}^{[3]}$ $\mathbb{B}^{[3]}$ is defined as the derivative of two-body correlations with respect to the magnetic field b:

$$
\chi_B^{[3]} \equiv \left. \frac{\partial}{\partial b} \left(\frac{\chi_{m\uparrow, m\uparrow} - \chi_{m\downarrow, m\downarrow}}{2} \right) \right|_{b=0} = -\chi_{\sigma\sigma\sigma}^{[3]} + \chi_{\sigma\sigma'\sigma'}^{[3]}.
$$
\n(4.11)

The magnetic field b is applied to the impurity levels $\sigma = (m, s)$, for $m = 1, 2, \ldots, N/2$ and $s = \uparrow, \downarrow$, inducing the spin Zeeman splitting, as

$$
\epsilon_{d,m,\uparrow} = \epsilon_d - b, \qquad \epsilon_{d,m,\downarrow} = \epsilon_d + b. \qquad (4.12)
$$

In the following sections, we investigate how three-body correlations influence low-energy transport in the strong interaction limit across a broad range of impurity levels, ϵ_d .

FIG. 1. NRG results for N_d , z, and \tilde{K} plotted as functions of ϵ_d in the $U \to \infty$ limit with $\pi \Delta/D = 0.01$: (a) $N = 2$ and (b) $N = 4$.

V. NRG RESULTS FOR SU(N) FERMI LIQUID PARAMETERS FOR $U \rightarrow \infty$ ANDERSON MODEL

In this section, we discuss the $SU(N)$ Fermi-liquid (FL) parameters, obtained with the NRG in the $U \to \infty$ limit with $\pi\Delta/D = 0.01$. More detailed procedures for the NRG are described in Appendix [B.](#page-15-11)

A. ϵ_d dependence of N_d and two-body functions

The NRG results for the number of impurity electrons N_d , the renormalization factor z, and the rescaled Wilson ratio K are plotted in Fig. [1,](#page-4-2) as functions of ϵ_d for (a) $N = 2$ and (b) $N = 4$.

The occupation number N_d (= $N\delta/\pi$) increases as the impurity level ϵ_d decreases. It approaches the maximum possible value of $N_d \simeq 1$ in the Kondo regime at $\epsilon_d \ll$ $-\Delta,$ while it becomes nealy empty $N_d\simeq 0$ in the opposite limit $\epsilon_d \gg \Delta$. In particular, N_d increases rapidly in the valence fluctuation (VF) regime, as ϵ_d decreases. Note that in the Kondo regime, the phase shift approaches $\delta \to \pi/N$, which corresponds to $\delta \to \pi/2$ and $\pi/4$ for $N = 2$ and 4, respectively. decreases. **2 0 2 4 6 8 10**

The rescaled Wilson ratio $\tilde{K} = (N-1)(R-1)$ approaches its upper-bound, $K \to 1$, as ϵ_d decreases, reflecting the strong electron correlations characteristics of the Kondo regime. Correspondingly, the renormalization factor z becomes significantly small in this regime. This factor z also determines the width of renormalized level width, $\Delta = z\Delta$, and the characteristic energy scale, de-fined in Eq. [\(4.2\)](#page-3-2), as $T^*/(\pi \Delta) = z/(4 \sin^2 \delta)$.

Figure [2](#page-4-3) shows the results of renormalized impurity level $\tilde{\epsilon}_d = \Delta \cot \delta$ defined in Eq. [\(A5\)](#page-13-1). In the Kondo regime $\epsilon_d \ll -\Delta$, it approaches the Fermi level, $\tilde{\epsilon}_d \to 0$ keeping the ratio $\tilde{\epsilon}_d/\Delta \to \cot \pi/N$ as a constant (e.g., 1)
for $N = 4$ while 0 for $N = 2$). In the eposite limit $\epsilon \gg$ for $N = 4$ while 0 for $N = 2$). In the opposite limit, $\epsilon_d \gg$ Δ , the renormalized level $\tilde{\epsilon}_d$ asymptotically approaches
the population position as the occupation number N the noninteracting position as the occupation number N_d decreases.

FIG. 2. The renormalized impurity level $\tilde{\epsilon}_d$, defined in Eq. [\(A5\)](#page-13-1), is plotted over a wide range of ϵ_d in the $U \to \infty$ limit with $\pi\Delta/D = 0.01$: (a) $N = 2$ and (b) $N = 4$. The thin straight line represents the position of bare impurity level $\epsilon_d/(\pi\Delta)$.

B. ϵ_d dependence of three-body correlations

NRG results for the dimensionless three-body correlation functions Θ_{I} , $-\Theta_{\text{II}}$, and Θ_{III} are plotted in Fig. [3.](#page-5-0) Among these three components, the last one, $\Theta_{\rm I\!I\!I}$, which is absent for $N = 2$ by definition, contributes to the next-to-leading order transport coefficients of multilevel impurities with $N \geq 3$.

In the limit $\epsilon_d \to \infty$, the intra-level component Θ _I approaches the noninteracting value, while the other two components vanish as the impurity level becomes nearly empty, $N_d \rightarrow 0$:

$$
\Theta_{\mathrm{I}} \xrightarrow{\epsilon_d \to \infty} -2, \quad \widetilde{\Theta}_{\mathrm{II}} \xrightarrow{\epsilon_d \to \infty} 0, \quad \widetilde{\Theta}_{\mathrm{III}} \xrightarrow{\epsilon_d \to \infty} 0. \quad (5.1)
$$

Figure [3](#page-5-0) clearly shows that, in the Kondo regime $\epsilon_d \rightarrow$ $-\infty$, all three components of the three-body correlation function converge to the same value for $N \geq 3$:

$$
\lim_{\epsilon_d \to -\infty} \Theta_{\mathcal{I}} = -\lim_{\epsilon_d \to -\infty} \widetilde{\Theta}_{\mathcal{I}} = \lim_{\epsilon_d \to -\infty} \widetilde{\Theta}_{\mathcal{I}\mathcal{I}} \equiv \Theta_{\text{Kond}}^{1/N} . \tag{5.2}
$$

This occurs because the contributions of $\chi_B^{[3]}$, which appear in Eqs. (4.8) – (4.10) , dominate three-body correlations, while the other two terms, $\partial \chi_{\sigma\sigma}/\partial \epsilon_d$ and $\partial \chi_{\sigma \sigma'} / \partial \epsilon_d$, are suppressed in the Kondo regime [\[58\]](#page-16-10). The value $\Theta_{\text{Kond}}^{1/N}$ of the three-body correlation in this limit can be compared with the one derived from the Bethe ansatz solution for the $SU(N)$ Kondo model by Mora et al. [\[44,](#page-16-7) [45\]](#page-16-16) (see Appendix [C\)](#page-15-12). For $N = 4$, our NRG result closely agrees with the value $\Theta_{\text{Kond}}^{1/4} = -1.11$. Note that, for $N = 2$, the three-body correlations vanish in SU(2) Kondo regime due to electron-hole symmetry.

VI. NONLINEAR CURRENT THROUGH $U \rightarrow \infty$ QUANTUM DOTS

In this section, we examine the low-energy behavior of the differential conductance dI/dV through $SU(N)$ quantum dots. The exact low-energy asymptotic form

FIG. 3. Dimensionless three-body correlation functions Θ_{I} , $-\Theta_{\text{II}}$ and Θ_{III} , defined in Eqs. [\(4.4\)](#page-3-5) and [\(4.5\)](#page-3-6), are plotted as functions of ϵ_d in the $U \to \infty$ limit with $\pi \Delta/D = 0.01$: (a) $N = 2$ and (b) $N = 4$.

of the nonlinear current I has recently been derived up to terms of order $(eV)^3$ at $T=0$, taking into account the tunneling and bias asymmetries [\[57\]](#page-16-19),

$$
\frac{dI}{dV} = \frac{Ne^2}{h} (1 - \gamma_{\text{dif}}^2) \times \left[\sin^2 \delta + C_V^{(2)} \frac{eV}{T^*} - C_V^{(3)} \left(\frac{eV}{T^*} \right)^2 + \cdots \right].
$$
 (6.1)

The coefficient $C_V^{(2)}$ $\int_V^{(2)}$ for the order eV term of dI/dV is determined by the static susceptibilities [\[34,](#page-16-31) [35\]](#page-16-2):

$$
C_V^{(2)} = \frac{\pi}{4} \left[\alpha_{\text{dif}} \left(1 - \tilde{K} \right) - \gamma_{\text{dif}} \, \tilde{K} \right] \sin 2\delta \,. \tag{6.2}
$$

This coefficient $C_V^{(2)}$ $V^{(2)}$ linearly depends on the tunneling and bias asymmetries, i.e., γ_{dif} and α_{dif} . Therefore, it vanishes, $C_V^{(2)} = 0$, when both of these asymmetries are absent, specifically for $\alpha_{\text{dif}} = \gamma_{\text{dif}} = 0$. The magnitude of $C_V^{(2)}$ $V_K⁽²⁾$ also depends on the rescaled Wilson ratio K and $\sin 2\delta$, which arises through the derivative of the spectral function $\rho'_{d\sigma} = \sin 2\delta / (4T^* \Delta)$ defined in Eq. [\(A10\)](#page-13-2). Equation [\(6.2\)](#page-5-1) reveals that effects of bias asymmetry α_{dif} vanish in the limit of $\tilde{K} \to 1$, where the charge fluctuations are suppressed due to strong electron correlations.

The order $(eV)^2$ term of dI/dV depends on the threebody correlation functions:

$$
C_V^{(3)} = \frac{\pi^2}{64} \left(W_V + \Theta_V \right), \tag{6.3}
$$

$$
W_V \equiv -\cos 2\delta \left[1 + 3 \alpha_{\text{dif}}^2 - 6(\alpha_{\text{dif}}^2 + \alpha_{\text{dif}}^2) \tilde{K} \right. \n\left. + \left\{ \frac{5}{N-1} + 3 \alpha_{\text{dif}}^2 + 6 \alpha_{\text{dif}}^2 \gamma_{\text{dif}} + \frac{3(N-2)}{N-1} \gamma_{\text{dif}}^2 \right\} \tilde{K}^2 \right],
$$
\n
$$
\Theta_V \equiv \left(1 + 3 \alpha_{\text{dif}}^2 \right) \Theta_{\text{I}} + 3 \left(1 + 3 \alpha_{\text{dif}}^2 + 4 \alpha_{\text{dif}}^2 \gamma_{\text{dif}}^2 \right) \tilde{\Theta}_{\text{II}} \right. \n\left. + 6 \left(\alpha_{\text{dif}}^2 + 2 \alpha_{\text{dif}}^2 \gamma_{\text{dif}}^2 + \gamma_{\text{dif}}^2 \right) \tilde{\Theta}_{\text{III}} \right].
$$
\n(6.5)

FIG. 4. Linear conductance $\sin^2 \delta$ and noise $\sin^2 \delta (1 - \sin^2 \delta)$ are plotted as functions of ϵ_d in the $U \to \infty$ limit with $\pi\Delta/D = 0.01$: (a) $N = 2$ and (b) $N = 4$.

The coefficient $C_V^{(3)}$ $V^{(3)}$ also depends on the tunneling and bias asymmetries through the quadratic terms, α_{dif}^2 , $\alpha_{\text{dif}}^{\text{}}\gamma_{\text{dif}}^{\text{}}$, and γ_{dif}^2 [\[57\]](#page-16-19).

When both the chemical potentials and tunnel couplings are inverted such that $(\alpha_{\text{dif}}, \gamma_{\text{dif}}) \rightarrow (-\alpha_{\text{dif}}, \gamma_{\text{dif}})$ $-\gamma_{\text{dif}}^{\text{(2)}}$, the coefficients $C_V^{(2)}$ $V^{(2)}$ and $C_V^{(3)}$ $V^{(3)}$ exhibit odd and even responses, respectively; that is, $C_V^{(2)} \rightarrow -C_V^{(2)}$ $V^{(2)}$ and $C_V^{(3)} \to C_V^{(3)}$ $V^{(3)}$.

A. NRG results for $\sin^2 \delta$ and $C_V^{(2)}$ for $U \to \infty$

Example 18
 Example 18 NRG results for $\sin^2 \delta$, which determines the linear conductance $dI/dV|_{V=0}$ through the $U \to \infty$ Anderson impurity, are plotted in Fig. [4](#page-5-2) for (a) $N = 2$ and (b) $N = 4$. In this strong interaction limit, the phase shift varies within the range $0 < \delta < \pi/N$ as the occupation number varies in the range $0 < N_d < 1$. Therefore, in the Kondo limit $\epsilon_d \to -\infty$, the linear conductance reaches the value $\sin^2(\pi/N)$, which equals 1 for SU(2) and 1/2 for $SU(4)$.

The order eV term of dI/dV , described in Eq. [\(6.1\)](#page-5-3), emerges when tunneling asymmetry γ_{dif} , bias asymmetry α_{dif} , or both are present. The dependence of the coefficient $C_V^{(2)}$ $V^{(2)}$ on these asymmetries arises through the bias window, i.e., $f_L - f_R$ in Eq. [\(2.11\)](#page-2-2), and is determined by the spectral function $A^{(1)}(\omega)$, which is exact up to linear order terms in ω and eV ,

$$
\pi \Delta A^{(1)}(\omega) \equiv \frac{\tilde{\Delta}^2}{\left(\omega - \tilde{\epsilon}_d^{(1)}\right)^2 + \tilde{\Delta}^2},\tag{6.6}
$$

$$
\tilde{\epsilon}_d^{(1)} \equiv \tilde{\epsilon}_d + \frac{\alpha_{\text{dif}} + \gamma_{\text{dif}}}{2} \tilde{K} eV. \tag{6.7}
$$

Here, $\tilde{\epsilon}_d^{(1)}$ $\frac{d^{(1)}}{d}$ is the renormalized impurity level calculated up to terms of order eV , and $\tilde{\epsilon}_d = \tilde{\Delta} \cot \delta$, with being $\tilde{\Delta}$ the renormalized level width defined in Appendix [A.](#page-13-0)

The coefficient $C_V^{(2)}$ $V^{(2)}$ vanishes in the limit $\epsilon_d \to +\infty$, where $\delta \to 0$:

$$
C_V^{(2)} \xrightarrow{\epsilon_d \to +\infty} 0. \tag{6.8}
$$

FIG. 5. Coefficient for the V^2 -nonlinear current, defined in Eq. [\(6.2\)](#page-5-1), plotted as a function of ϵ_d , for (a) $N = 2$ and (b) $N = 4$. The results are scaled such that $C_V^{(2)}/\gamma_{\text{dif}}$ corresponds to the case with symmetric bias voltages ($\alpha_{\text{dif}} = 0$), and $C_V^{(2)}/\alpha_{\text{dif}}$ corresponds to the case with symmetric tunnel couplings ($\gamma_{\text{dif}} = 0$).

In the opposite limit $\epsilon_d \to -\infty$, the FL parameters approach $\delta \to \pi/N$ and $\widetilde{K} \to 1$. Thus, $C_V^{(2)}$ $V^{(2)}$ approaches

$$
C_V^{(2)} \xrightarrow{\epsilon_d \to -\infty} -\frac{\pi}{4} \gamma_{\text{dif}} \sin \frac{2\pi}{N}, \qquad (6.9)
$$

which results in 0 for SU(2) and $-(\pi/4)\,\gamma_\mathrm{dif}^{\phantom i}$ for SU(4). In this limit, $C_V^{(2)}$ $V^{(2)}$ becomes independent of the bias asymmetry α_{dif} as charge fluctuations are suppressed by the strong electron correlation.

Figure [5](#page-6-0) presents the NRG results for $C_V^{(2)}$ $V^{(2)}$ in two different cases. The first case involves the rescaled coefficient $C_V^{(2)}$ $\frac{N^{(2)}}{V}$ / γ_{dif} , obtained under symmetric bias voltages $(\alpha_{\text{dif}}^{\text{}}=0)$, with finite tunneling asymmetries $(\gamma_{\text{dif}}^{\text{}}\neq0)$. The second case involves $C_V^{(2)}$ $\int_V^{(2)}/\alpha_{\text{dif}}$, obtained under symmetric tunnel couplings ($\gamma_{\text{dif}}=0$) with finite bias asymmetries ($\alpha_{\text{dif}} \neq 0$). Note that the coefficient $C_V^{(2)}$ $V^{(2)}$ is proportional to the factor $\sin 2\delta$ that exhibits a maximum at $\delta = \pi/4$. This maximum occurs in the valence fluctuation region for $N = 2$, while it occurs in the Kondo regime for $N = 4$.

For SU(2) quantum dots, the peak of $C_V^{(2)}$ $\frac{N^{(2)}}{V} / \alpha_{\text{dif}}$ and the dip of $C_V^{(2)}$ $V^{(2)}/\gamma_{\text{dif}}$ appearing in Fig. [5](#page-6-0) (a) are mainly caused by the maximum of $\sin 2\delta$ that occurs in the valence fluctuation region. In contrast, for SU(4) quantum dots, both K and $\sin 2\delta$ increase as ϵ_d decreases. Consequently, the magnitude $|C_V^{(2)}|$ $\frac{N^{(2)}}{V}$ γ_{dif} for the bias symmetric case increases as ϵ_d decreases from the valence fluctuation region toward the 1/4-filling Kondo regime. The peak that emerges for $C_V^{(2)}$ $\int_V^{(2)}/\alpha_{\text{dif}}$ in the valence fluctuation region for $N = 4$ is due to the behavior of the factor $1 - K$, which decreases as ϵ_d decreases.

$\, {\bf B.} \quad C_V^{(3)} \colon \, {\bf order} \, \left(eV \right)^2 \, {\bf term \, \, of} \, \, dI/dV$

In this subsection, we discuss the properties of $C_V^{(3)}$ V defined in Eq. [\(6.3\)](#page-5-4), as the coefficient for the order $(eV)^2$

FIG. 6. Coefficients $C_V^{(3)}$, W_V , and Θ_V for the V^3 -nonlinear current, defined in Eq. [\(6.3\)](#page-5-4), plotted as functions of ϵ_d for a symmetric junction ($\gamma_{\text{dif}} = \alpha_{\text{dif}} = 0$): (a) $N = 2$ and (b) $N=4.$

term of dI/dV .

In the limit $\epsilon_d \to +\infty$, the two-body part W_V and the three-body part Θ_V approach their noninteracting values, which take the following forms:

$$
W_V \xrightarrow{\epsilon_d \to +\infty} -\left(1 + 3\alpha_{\text{dif}}^2\right),\tag{6.10}
$$

$$
\Theta_V \xrightarrow{\epsilon_d \to +\infty} -2\left(1 + 3\alpha_{\text{dif}}^2\right). \tag{6.11}
$$

In the opposite limit $\epsilon_d \to -\infty$, the phase shift and the rescaled Wilson ratio approach $\delta \to \pi/N$ and $\widetilde{K} \to$ 1, respectively, and the three-body correlation functions converge to the same value $\Theta_{\text{I}} = -\widetilde{\Theta}_{\text{II}} = \widetilde{\Theta}_{\text{III}} \rightarrow \Theta_{\text{Kond}}^{1/N}$, as described in Eq. [\(5.2\)](#page-4-4). Consequently, $C_V^{(3)}$ $V^{(3)}$ becomes independent of the bias asymmetry α_{dif} in the Kondo regime, and in the $1/N$ -filling case it takes the following form:

$$
W_V \xrightarrow{\epsilon_d \to -\infty} -\left[1 + \frac{5}{N-1} + \frac{3(N-2)}{N-1} \gamma_{\text{dif}}^2\right] \cos \frac{2\pi}{N},\tag{6.12}
$$

$$
\Theta_V \xrightarrow{\epsilon_d \to -\infty} -2 \left(1 - 3\gamma_{\text{dif}}^2\right) \Theta_{\text{Kond}}^{1/N} . \tag{6.13}
$$

Here, $\Theta_{\text{Kond}}^{1/2} = 0$ for $N = 2$ due to the electron-hole symmetry, and $\Theta_{\text{Kond}}^{1/4} = -1.11$ for $N = 4$. The twobody part W_V depends on the factor $-\cos(2\pi/N)$, which reaches a maximum for $N = 2$ but vanishes for $N = 4$. Consequently, the three-body correlation Θ_V dominates in the $1/4$ -filling Kondo regime of $SU(4)$ quantum dots, whereas in the SU(2) Kondo limit, $C_V^{(3)}$ $V^{(3)}$ is determined solely by the two-body correlation W_V .

The NRG results for $C_V^{(3)}$ $V^{(3)}$, W_V , and Θ_V for symmetric junctions, $\alpha_{\text{dif}}^{} = 0$ and $\gamma_{\text{dif}}^{} = 0$, are plotted vs ϵ_d in Fig. [6.](#page-6-1) For $SU(2)$ quantum dots, W_V becomes the dominant term and approaches $W_V \rightarrow 6$ in the 1/2-filling Kondo regime $\epsilon_d \rightarrow -\infty$, where Θ_V vanishes due to electron-hole symmetry. Outside the Kondo regime, however, ${\cal W}_V$ and Θ_V become comparable in the valence fluctuation region, $\epsilon_d/\pi\Delta \gtrsim -0.5$. In contrast, for SU(4) quantum dots, the three-body contribution dominates C_V in the 1/4filling Kondo regime, where it reaches the value $C_V \rightarrow$

FIG. 7. $C_V^{(3)}$, W_V , and Θ_V for SU(4) QDs are plotted vs ϵ_d , with varying tunneling asymmetry $\gamma_{\text{dif}} = 0(\circ), 0.35(\blacktriangle),$ $1/\sqrt{3}(\square)$, 0.75(\blacktriangledown), and 0.9(\diamondsuit), while keeping the bias voltage symmetric ($\alpha_{\text{dif}} = 0$).

 $-2\Theta_{\text{Kond}}^{1/4} = 2.22 \cdots$. In the valence fluctuation region, $\epsilon_d/\pi\Delta \gtrsim -3$, both the two-body W_V and three-body Θ_V parts give contribute comparably to C_V .

1. $C_V^{(3)}$ in bias symmetric case: $\alpha_{\text{dif}} = 0$

We now consider the behavior of $C_V^{(3)}$ $V^{(3)}$ in the biassymmetric case $\alpha_{\text{dif}}^{\text{}}=0$, where the tunneling asymmetry affects W_V and Θ_V^{un} through the order γ_{dif}^2 terms that ap-pears in Eqs. [\(6.4\)](#page-5-5) and [\(6.5\)](#page-5-6). The NRG results for $C_V^{(3)}$ V of SU(4) quantum dots at $\alpha_\mathrm{dif}^{}=0$ are plotted against ϵ_d in Fig. [7,](#page-7-0) for several values of γ_{dif} values. The coefficient $C_V^{(3)}$ $\gamma_V^{(3)}$ depends significantly on γ_{dif}^2 in both the valence fluctuation and Kondo regimes, where $\epsilon_d/(\pi\Delta) \lesssim 0$. In particular, the two-body part W_V vanishes in the 1/4filling SU(4) Kondo regime, where $\delta = \pi/4$ [see Fig. [7\(](#page-7-0)b)]. Thus, the plateau structure of $C_V^{(3)}$ $V^{(0)}$ in the Kondo regime is determined solely by the three-body part Θ_V , as shown in Fig. [7\(](#page-7-0)c). The plateau height of Θ_V decreases as the tunneling asymmetry γ_{dif} increases from 0 and changes sign at $\gamma_{\text{dif}}^2 = 1/3$. In the valence fluctuation regime, $C_V^{(3)}$ $V^{(3)}$ exhibits a local minimum for large tunneling asymmetries, primarily due to the two-body part W_V . Note that $C_V^{(3)}$ $V^{(3)}$ for SU(2) quantum dots is unaffected by tunneling asymmetry in the bias symmetric case αdif = 0, as **3 2 1 0 1 2**

FIG. 8. Behavior of $C_V^{(3)}$ at large bias asymmetry $\alpha_{\text{dif}}^{\text{}}=1$ is described as a function of ϵ_d for (left panel) $N = 2$ and (right panel) $N = 4$. Top panels: Tunneling asymmetry is varied as $\gamma_{\text{dif}} = -0.9($ (•), $-0.75($ •), $-1/\sqrt{3}$ (**v**), $-0.35($ **■**), $0(\times)$, $0.35(\Box)$, $1/\sqrt{3}(\triangle)$, $0.75(\circ)$, and $0.9(\diamond)$. In addition, twobody part W_V and three-body part Θ_V are plotted together with $C_V^{(3)}$ for two large opposite tunneling asymmetries: (middle panels) $\gamma_{\text{dif}} = 0.9$, and (bottom panels) $\gamma_{\text{dif}} = -0.9$.

the γ_{dif}^2 term vanishes for $N=2$. Therefore, the curves shown in Fig. [6](#page-6-1) (a) for $N = 2$ remain unchanged in this case, even at finite $\gamma_{\text{dif}}^{\text{}}$.

2. $C_V^{(3)}$ under large bias asymmetry: $\alpha_{\text{dif}}^{\text{}} = 1$

Bias and tunneling asymmetries affect the coefficient $C_V^{(3)}$ ⁽³⁾ through the quadratic terms α_{dif}^2 , α_{dif}^2 and γ_{dif}^2 , which appear in Eqs. (6.4) and (6.5) . In order to clarify the effects due to bias asymmetry, we set the bias parameter to be $\alpha_{\text{dif}} = 1$, representing the situation where one of the two leads is grounded, i.e., $\mu_R = 0$ and $\mu_L = eV$. In this case, the cross term $\alpha_{\mathrm{dif}}^{}\gamma_{\mathrm{dif}}^{}$ changes sign depending on whether γ_{dif} is positive or negative.

NRG results for $C_V^{(3)}$ $V^{(3)}$ are plotted versus ϵ_d for several values of γ_{dif} in Fig. [8\(](#page-7-1)a) and 8(b) for $N = 2$ and $N=4$, respectively. The plateau structure of $C_V^{(3)}$ $V^{(0)}$ in the Kondo regime, $\epsilon_d \to -\infty$, is determined by Eqs. [\(6.12\)](#page-6-2) and (6.13) ; therefore the plateau height does not depend on the bias asymmetry α_{dif} . For $N = 4$, the plateau value of $C_V^{(3)}$ $\chi^{(3)}$ decreases as the tunneling asymmetry γ_{dif}^2 increases, as shown in Fig. [8\(](#page-7-1)b). In the valence fluctuation regime, contributions from the cross term dif γ_{dif} become significant. In particular, $C_V^{(3)}$ $V^{(3)}$ exhibits a peak near $\epsilon_d/(\pi\Delta) \simeq -1$ for large positive $\gamma_{\text{dif}}^{\text{}}$, where $\alpha_{\text{dif}}^{\text{}}\gamma_{\text{dif}}^{\text{}} > 0$, and the bias and tunneling asymmetries cooperatively enhance charge transfer from one of the electrodes (the left lead in this case). The peak emerges more prominently for $SU(4)$ quantum dots than for $SU(2)$. The two-body W_V part and three-body part Θ_V for a large positive cross term ($\alpha_{\text{dif}} = 1.0$ and $\gamma_{\text{dif}} = 0.9$) are plotted in Figs. $8(c)$ $8(c)$ and $8(d)$. The results clearly show that the peak structure of $C_V^{(3)}$ $\mathcal{V}^{(5)}$ is caused by three-body contributions Θ_V . In contrast, for a negative cross term $\alpha_{\text{dif}}^{\dagger}\gamma_{\text{dif}}^{\dagger} < 0$, neither W_V nor Θ_V , exhibits a peak in the valence fluctuation regime, and thus $C_V^{(3)}$ $V^{(3)}$ exhibits monotonous ϵ_d dependence, as shown in Figs. [8\(](#page-7-1)e) and 8(f) for $\alpha_{\text{dif}}^{\text{}}=0$ and $\gamma_{\text{dif}}^{} = -0.9$. and the values are not part of $\frac{1}{\sqrt{2}}$ extintion and the positive stern diff γ_{diff} be $\frac{1}{\sqrt{2}}$ coefficients C_S , W_S , and other body part γ_{diff} be the three-body part γ_{diff} be γ_{diff} be $\gamma_{\$

VII. NONLINEAR NOISE OF CURRENT THROUGH $U \rightarrow \infty$ QUANTUM DOTS

We next consider the low-bias behavior of the current noise $S_{\text{noise}}^{\text{QD}}$ for symmetric junctions, $\gamma_{\text{dif}}^{\gamma} = \alpha_{\text{dif}}^{\gamma} = 0$, in the $SU(N)$ case. The current-current correlation function defined in Eq. [\(2.17\)](#page-2-3) can be expanded up to terms of order $|eV|^3$ at $T=0$, as

$$
S_{\text{noise}}^{\text{QD}} = \frac{2Ne^2|eV|}{h} \left[\sin^2 \delta \left(1 - \sin^2 \delta\right) + C_S \left(\frac{eV}{T^*}\right)^2 + \cdots \right] \tag{7.1}
$$

.

The first term in the bracket corresponds to the order $|eV|$ shot noise, which can also be expressed in the form $\sin^2 \delta (1 - \sin^2 \delta) = (1 - \cos 4\delta)/8$. Note that this term is maximized at the 1/4-filling point, where $\delta = \pi/4$, and the phase shift δ varies in the range $0 < \delta < \pi/N$ in the strong interaction limit $U \to \infty$. The ϵ_d dependence of this linear noise in this case is shown in Fig. [4](#page-5-2) for (a) $N = 2$ and (b) $N = 4$. For SU(2) quantum dots, the linear noise exhibits a sharp peak at 1/4 filling, which occurs in the valence fluctuation regime where the electron correlation is not significant. In contrast, for SU(4), the maximum of linear noise emerges in the $1/4$ -filling Kondo regime as a wide plateau.

The coefficient C_S for the order $|eV|^3$ term can be divided into the two-body part W_S

FIG. 9. Coefficients C_s , W_s , and Θ_s for the nonlinear noise plotted as functions of ϵ_d , for (a) $N = 2$, and (b) $N = 4$.

$$
\Theta_S \ [55, 58]:
$$

\n
$$
C_S = \frac{\pi^2}{192} (W_S + \Theta_S),
$$
\n(7.2)

$$
W_S \equiv \cos 4\delta + \left[4 + 5 \cos 4\delta + \frac{3}{2} (1 - \cos 4\delta)(N - 2) \right] \frac{\tilde{K}^2}{N - 1}, (7.3)
$$

$$
\Theta_S \equiv -\Theta_V \cos 2\delta = -\frac{\sin 4\delta}{4\pi \chi_{\sigma\sigma}^2} \left(\chi_{\sigma\sigma\sigma}^{[3]} + 3\widetilde{\chi}_{\sigma\sigma'\sigma'}^{[3]} \right). (7.4)
$$

Note that Θ_S exhibits a sin 4 δ dependence because Θ_V , defined by Eqs. (4.4) and (6.5) , has an extra factor of $\sin 2\delta$.

These two parts, W_S and Θ_S , approach their noninteracting values in the limit of $\epsilon_d \to +\infty$:

$$
W_S \xrightarrow{\epsilon_d \to +\infty} 1, \qquad \Theta_S \xrightarrow{\epsilon_d \to +\infty} 2. \tag{7.5}
$$

In contrast, in the 1/N-filling Kondo limit $\epsilon_d \rightarrow -\infty,$ the Wilson ratio and three-body correlation functions take the strong coupling values: $K \to 1$ and $\Theta_{\text{I}} + \Theta_{\text{II}} \to 0$, and thus

$$
W_S \xrightarrow{\epsilon_d \to -\infty} \frac{1}{2} \left(3 + \frac{5}{N-1} \right) + \frac{1}{2} \left(\frac{13}{N-1} - 1 \right) \cos \frac{4\pi}{N},\tag{7.6}
$$

$$
\Theta_S \xrightarrow{\epsilon_d \to -\infty} 2 \Theta_{\text{Kond}}^{1/N} \cos \frac{2\pi}{N} \,. \tag{7.7}
$$

Here, $\Theta_{\text{Kond}}^{1/2} = 0$ for $N = 2$ and $\Theta_{\text{Kond}}^{1/4} = -1.11$ for $N = 4$ (see Appendix [C\)](#page-15-12).

NRG results for C_S , W_S , and Θ_S are plotted as functions of ϵ_d in Fig. [9.](#page-8-1) For SU(2) quantum dots, C_S exhibits the plateau structure in the Kondo regime, which in this case is determined by the two-body contributions W_S since Θ_S vanishes due to the electron-hole symmetry. The coefficient C_S for $N = 2$ also exhibits a dip with a negative value at $\epsilon_d/\pi\Delta \simeq -0.5$ in the valence fluctuation regime. The structure of this dip is determined by the oscillatory $\cos 4\delta$ term in the two-body part, $W_S \xrightarrow{N=2} 4\widetilde{K}^2 + (1+5\widetilde{K}^2)\cos 4\delta$, which reaches a minimum near $\delta \simeq \pi/4$. As ϵ_d rises above the Fermi

level, i.e., for $\epsilon_d / \pi \Delta \gtrsim 0$, both W_S and Θ_S contribute comparably.

In the $1/4$ -filling Kondo regime for $SU(4)$ quantum dots, three-body contribution Θ_S vanishes since $\cos 2\delta \xrightarrow{\delta \to \pi/4} 0$, although the correlation function $\Theta_{\text{Kond}}^{1/4}$ itself is finite [see Eq. [\(7.7\)](#page-8-2)], which is one of the characteristics of the 1/4-filling Kondo state. Thus, the Kondo plateau for C_S , which emerges in Fig. [9\(](#page-8-1)b) for $\epsilon_d/(\pi\Delta) \lesssim 3.5$, is determined by the two-body contribution W_S through Eq. [\(7.6\)](#page-8-3). Note that for U-finite quantum dots with $N > 4$ levels, the Kondo effects occur at a number of integer-filling points where the phase shift takes the values of $\delta/\pi = 1/N$, $2/N$, ..., $(N-1)/N$. Hence, the three-body part Θ_S contributes to the nonlinear current noise for most of the $SU(N)$ Kondo states, except for those at $1/2$ - and $1/4$ -fillings [\[44,](#page-16-7) [58\]](#page-16-10).

The results shown in Fig. [9\(](#page-8-1)b) also reveal that the coefficient C_S for infinite-U SU(4) quantum dots is positive throughout the entire range of ϵ_d . In particular, C_S remains positive at the local minimum that emerges in the valence fluctuation regime. Note that the minimum of C_S for finite U reaches a negative value for small interactions, as demonstrated in Ref. [58.](#page-16-10) The structure of this minimum is determined by comparable contributions from the two-body and three-body parts. As a result, the peak that appears in the two-body part near $\delta \simeq \pi/8$, due to the balance between the first term and the second $\cos 4\delta$ term in is the both of the University of the broad-off contribution of the broad-off contribution of the the both of $\sqrt{2}$ and \sqrt

$$
W_S \xrightarrow{N=4} \frac{1}{3} \left[7\widetilde{K}^2 + (3 + 2\widetilde{K}^2) \cos 4\delta \right], \qquad (7.8)
$$

becomes dominant, making the next leading order term of current noise positive $C_S > 0$.

VIII. THERMOELECTRIC TRANSPORT THROUGH $U \rightarrow \infty$ QUANTUM DOTS

Thermoelectric transport coefficients $\mathcal{L}_{n,\sigma}^{\text{QD}}$ for quantum dots, defined in Eq. [\(3.4\)](#page-2-4), can be calculated using the low-energy asymptotic form of $A_{\sigma}(\omega)$ that was obtained exactly up to terms of order ω^2 and T^2 , with the selfenergy $\Sigma_{\sigma}^{r}(\omega)$ described in [A](#page-13-0)ppendix A [\[57,](#page-16-19) [58\]](#page-16-10). Specifically, $\mathcal{L}_{0,\sigma}^{\text{QD}}$ and $\mathcal{L}_{2,\sigma}^{\text{QD}}$ can be determined up to the first two terms of the expansion with respect to T , using Eqs. [\(A24\)](#page-14-0) and [\(A25\)](#page-15-13). In contrast, solely the lowest-order term can be determined for $\mathcal{L}_{1,\sigma}^{\text{QD}}$, which gives the leadingorder term of the thermopower S_{OD} :

$$
S_{\rm QD} = -\frac{\pi^2}{3|e|} \frac{\sum_{\sigma} \rho'_{d\sigma}}{\sum_{\sigma} \rho_{d\sigma}} T + \cdots \frac{\text{SU}(N)}{6|e|} - \frac{\pi^3 \cot \delta}{T^*} T^* + \cdots
$$
\n(8.1)

In this section, we discuss the behavior of the next-toleading order terms of the linear conductance g and the thermal conductance κ_{QD} through the SU(N) Anderson
impurity in the $U \to \infty$ limit.

FIG. 10. Coefficients C_T , W_T , and Θ_T for the T^2 -conductance of QDs plotted as functions of ϵ_d : (a) $N = 2$, and (b) $N = 4$.

A. C_T : order T^2 term of g

The linear conductance defined in Eq. [\(3.1\)](#page-2-5) can be expanded at low temperatures as follows:

$$
g = \frac{Ne^2}{h} \left[\sin^2 \delta - C_T \left(\frac{\pi T}{T^*} \right)^2 + \cdots \right]. \tag{8.2}
$$

The coefficient C_T for the T^2 term can be divided into two-body part W_T and three-body part Θ_T [\[58\]](#page-16-10):

$$
C_T = \frac{\pi^2}{48} \left(W_T + \Theta_T \right), \tag{8.3}
$$

$$
W_T \equiv -\left(1 + \frac{2\tilde{K}^2}{N - 1}\right)\cos 2\delta, \qquad (8.4)
$$

$$
\Theta_T \equiv \Theta_{\rm I} + \widetilde{\Theta}_{\rm II} = \frac{\sin 2\delta}{2\pi} (4T^*)^2 \frac{\partial \chi_{\sigma\sigma}}{\partial \epsilon_d}.
$$
 (8.5)

In the limit of $\epsilon_d \to +\infty$, the Fermi liquid parameters approach the values $\delta \to 0$, $\widetilde{K} \to 0$, $\Theta_{I} \to -2$, and $\Theta_{\rm II} \rightarrow 0$. Thus,

$$
W_T \xrightarrow{\epsilon_d \to +\infty} -1, \qquad \Theta_T \xrightarrow{\epsilon_d \to +\infty} -2. \tag{8.6}
$$

In contrast, in the 1/N-filling Kondo regime, $\epsilon_d \to -\infty$, the parameters approach the values $\delta \to \pi/N$, $K \to 1$, $\Theta_{\rm I} + \Theta_{\rm II} \rightarrow 0$, so that

$$
W_T \xrightarrow{\epsilon_d \to -\infty} -\left(1 + \frac{2}{N-1}\right) \cos \frac{2\pi}{N}, \qquad (8.7)
$$

$$
\Theta_T \xrightarrow{\epsilon_d \to -\infty} 0. \tag{8.8}
$$

NRG results for C_T , W_T , and Θ_T are shown in Fig. [10.](#page-9-1) For SU(2) quantum dots, the plateau structure of C_T in the half-filled Kondo regime is determined by the twobody part W_T . Outside the plateau region, the threebody part Θ_T becomes comparable to the two-body part W_T as ϵ_d increases. The coefficient C_T changes sign in the middle of the valence fluctuation region and approaches the noninteracting value as ϵ_d increases further.

The coefficient C_T for SU(4) quantum dots takes a negative value in the $U \rightarrow \infty$ limit throughout the entire range of ϵ_d . The value of C_T for $\epsilon_d/(\pi\Delta) \lesssim -3$ is determined by the two-body part W_T , and it vanishes in the Kondo regime at $\epsilon_d \to -\infty$ as the phase shift approaches $\delta \to \pi/4$. The three-body part Θ_T for $N=4$ decays more rapidly than W_T as $\epsilon_d \to -\infty$, since the derivative of the diagonal susceptibility that appeared in the right-hand of Eq. [\(8.5\)](#page-9-2) becomes very small, $|\partial \chi_{\sigma\sigma}/\partial \epsilon_d| \ll 1/(4T^*)^2$, due to strong electron correlations. This result can also be compared to the previous findings obtained at finite U [\[58\]](#page-16-10), which revealed that Θ_T is significantly suppressed not only in the quarter-filling Kondo regime but also over a much broader range of electron filling, $1 \lesssim N_d \lesssim N - 1$ under strong interactions (e.g., $U/(\pi\Delta) \gtrsim 5$ for $N = 4$).

$\, {\bf B.} \quad \, C_{\kappa}^{\rm QD}{:}\ \, {\bf order} \; T^3 \; {\bf term \; of} \; \kappa_{\rm QD}$

The low-temperature expansion of thermal conductance κ_{OD} through quantum dots, defined in Eq. [\(3.3\)](#page-2-6), takes the following form in the $SU(N)$ symmetric case:

$$
\kappa_{\rm QD} = \frac{N\pi^2 T}{3h} \left[\sin^2 \delta - C_{\kappa}^{\rm QD} \left(\frac{\pi T}{T^*} \right)^2 \cdots \right]. \quad (8.9)
$$

The leading-order terms of the thermal conductance κ_{OD} and electrical conductance g satisfy the Wiedemann-Franz law in the zero-temperature limit, yielding $\kappa_{\rm QD}/(Tg) \xrightarrow{T\to 0} \pi^2/(3e^2)$. The coefficient $C_{\kappa}^{\rm QD}$ for the next-to-leading order term of the thermal conductance also consists of the two-body W_{κ}^{QD} and three-body $\Theta_{\kappa}^{\text{QD}}$ parts:

$$
C_{\kappa}^{\text{QD}} = \frac{7\pi^2}{80} \left(W_{\kappa}^{\text{QD}} + \Theta_{\kappa}^{\text{QD}} \right), \tag{8.10}
$$

$$
W_{\kappa}^{\text{QD}} \equiv \frac{1}{21} \left[10 - \left(11 + \frac{18\tilde{K}^2}{N - 1} \right) \cos 2\delta \right], \quad (8.11)
$$

$$
\Theta_{\kappa}^{\text{QD}} \equiv \Theta_{\text{I}} + \frac{5}{21} \tilde{\Theta}_{\text{II}}.
$$
\n(8.12)

In the limit of $\epsilon_d \rightarrow +\infty$, where $N_d \rightarrow 0$, the FL parameters approach the values $\delta \to 0$, $\widetilde{K} \to 0$, $\Theta_{\text{I}} \to -2$, and $\widetilde{\Theta}_{\mathbb{I}} \to 0$. Consequently, in this limit, $\Theta_{\kappa}^{\text{QD}}$ dominates because W_{κ}^{QD} becomes very small:

$$
W_{\kappa}^{\text{QD}} \xrightarrow{\epsilon_d \to +\infty} -\frac{1}{21}, \qquad \Theta_{\kappa}^{\text{QD}} \xrightarrow{\epsilon_d \to +\infty} -2. \tag{8.13}
$$

In the opposite limit $\epsilon_d \to -\infty$, the 1/N-filling Kondo effect occurs and the FL parameters take the values $\delta \rightarrow$ π/N , $K \to 1$, and $\Theta_{\text{I}} + \Theta_{\text{II}} \to 0$. Thus, we have

$$
W_{\kappa}^{\text{QD}} \xrightarrow{\epsilon_d \to -\infty} \frac{1}{21} \left[10 - \left(11 + \frac{18}{N - 1} \right) \cos \frac{2\pi}{N} \right], \tag{8.14}
$$

$$
\Theta_{\kappa}^{\text{QD}} \xrightarrow{\epsilon_d \to -\infty} \frac{16}{21} \Theta_{\text{Kond}}^{1/N} . \tag{8.15}
$$

FIG. 11. Coefficients C_{κ}^{QD} , W_{κ}^{QD} , and $\Theta_{\kappa}^{\text{QD}}$ for the T^3 thermal conductance of QDs plotted as functions of ϵ_d : (a) $N = 2$, and (b) $N = 4$.

Specifically, the dimensionless three-body correlation functions for $N = 2$ and $N = 4$ are given by $\Theta_{\text{Kond}}^{1/2} = 0$ and $\Theta_{\text{Kond}}^{1/4} = -1.11$, respectively, as mentioned earlier.

Kond . (8.15) **3 2 1 0 1 2** NRG results for C_{κ}^{QD} , W_{κ}^{QD} , and $\Theta_{\kappa}^{\text{QD}}$ are plotted as functions of ϵ_d in Fig. [11.](#page-10-1) For SU(2) quantum dots, C_{κ}^{QD} takes a positive value and exhibits a plateau structure in the half-filling Kondo regime $\epsilon_d/(\pi\Delta) \leq -1$, which is determined by the two-body part W_{κ}^{QD} since the three-body part $\Theta_{\kappa}^{\text{QD}}$ vanishes due to the electronhole symmetry. As ϵ_d decreases, the coefficient C_{κ}^{QD} changes sign in the valence fluctuation regime, taking a negative value that is determined by the three-body part $\Theta_{\kappa}^{\text{QD}}$. In contrast, for SU(4) quantum dots, the three-body part $\Theta_{\kappa}^{\text{QD}}$ dominates throughout the entire range of ϵ_d in the $U \to \infty$ limit, although the two-body part W_{κ}^{QD} also makes competitive contributions in the quarter-filling Kondo regime $\epsilon_d/(\pi\Delta) \lesssim -2$. As a result, the coefficient C_{κ}^{QD} takes a negative value over the whole filling range $0 < N_d < 1$ for $N = 4$.

IX. THERMOELECTRIC PROPERTIES OF $U \rightarrow \infty$ MAGNETIC ALLOYS

Three-body Fermi-liquid corrections also play an essential role in the low-energy properties of magnetic alloys (MA). Thermoelectric transport coefficients $\mathcal{L}_{n,\sigma}^{\text{MA}}$ for magnetic alloys, defined in Eq. [\(3.8\)](#page-3-7), can be calculated in the low-temperature Fermi liquid regime in a manner similar to those for quantum dots [\[58\]](#page-16-10). For instance, the leading-order term of the thermopower of magnetic alloys takes the same form as that of QDs, given in Eq. [\(8.1\)](#page-9-3), but with the opposite sign:

$$
S_{\text{MA}} = \frac{\pi^3 \cot \delta}{6|e|} \frac{T}{T^*} + \cdots. \tag{9.1}
$$

In this section, we discuss the behavior of the nextleading order terms of other transport coefficients, specifically the electrical resistivity ρ_{MA} and the thermal conductivity κ_{MA} of magnetic alloys.

$\mathbf{A.} \quad C_{\varrho}^{\text{MA}}$: order T^2 term of ϱ_{MA}

The electrical resistivity for magnetic alloys, defined as $\varrho_{\text{MA}} \equiv 1/\sigma_{\text{MA}}$ in Eq. [\(3.5\)](#page-3-1), takes the following form at low temperatures in the $SU(N)$ case:

$$
\varrho_{\text{MA}} = \frac{1}{\sigma_{\text{MA}}^{\text{unit}}} \left[\sin^2 \delta - C_{\varrho}^{\text{MA}} \left(\frac{\pi T}{T^*} \right)^2 + \cdots \right]. \quad (9.2)
$$

Here, $\sigma_{\text{MA}}^{\text{unit}}$ is the unitary-limit value of electric conductivity. The coefficient C_{ϱ}^{MA} for the order T^2 term consists of two-body W_{ϱ}^{MA} and three-body $\Theta_{\varrho}^{\text{MA}}$ parts,

$$
C_{\varrho}^{\text{MA}} = \frac{\pi^2}{48} \left(W_{\varrho}^{\text{MA}} + \Theta_{\varrho}^{\text{MA}} \right), \tag{9.3}
$$

$$
W_{\varrho}^{\text{MA}} \equiv 2 + \left(1 - \frac{2\tilde{K}^2}{N - 1}\right)\cos 2\delta, \qquad (9.4)
$$

$$
\Theta_{\varrho}^{\text{MA}} \equiv \Theta_{\text{I}} + \widetilde{\Theta}_{\text{II}} = (4T^*)^2 \frac{\sin 2\delta}{2\pi} \frac{\partial \chi_{\sigma\sigma}}{\partial \epsilon_d}.
$$
 (9.5)

Note that $\Theta_{\varrho}^{\text{MA}} = \Theta_T$, where Θ_T is the three-body part of C_T for quantum dots given in Eq. [\(8.5\)](#page-9-2).

In the limit of $\epsilon_d\to +\infty,$ the FL parameters approach the values $\delta \to 0$, $K \to 0$, $\Theta_{\text{I}} \to -2$, and $\Theta_{\text{II}} \to 0$. Therefore,

$$
W_{\varrho}^{\text{MA}} \xrightarrow{\epsilon_d \to +\infty} 3, \qquad \Theta_{\varrho}^{\text{MA}} \xrightarrow{\epsilon_d \to +\infty} -2. \tag{9.6}
$$

In the opposite limit $\epsilon_d \to -\infty$, the 1/N-filling Kondo effect occurs, and the FL parameters take values δ \rightarrow π/N , $K \to 1$, and $\Theta_{\text{I}} + \Theta_{\text{II}} \to 0$. Thus,

$$
W_{\varrho}^{\text{MA}} \xrightarrow{\epsilon_d \to -\infty} 2 + \left(1 - \frac{2}{N - 1}\right) \cos \frac{2\pi}{N}, \qquad (9.7)
$$

$$
\Theta_{\varrho}^{\text{MA}} \xrightarrow{\epsilon_d \to -\infty} 0. \tag{9.8}
$$

NRG results for C_{ϱ}^{MA} , W_{ϱ}^{MA} , and $\Theta_{\varrho}^{\text{MA}}$ in the $U \to \infty$ limit are plotted in Fig. [12.](#page-11-0) In contrast to the coefficient C_T for the T^2 -conductance of quantum dots, which can change sign, C_{ϱ}^{MA} remains positive throughout the entire range of ϵ_d , for both $N = 2$ and $N = 4$. In the SU(2) case, it takes the value $(48/\pi^2)C_{\varrho}^{\text{MA}} \xrightarrow{\epsilon_d \to -\infty} 3$ in the half-filling Kondo regime, at which the two-body part W_{ϱ}^{MA} dominates since the three-body part $\Theta_{\varrho}^{\text{MA}}$ vanishes due to electron-hole symmetry. Note that the prefactor $(1 - \frac{2\tilde{K}^2}{N-1})$ for the cos 2δ term in W_{ϱ}^{MA} , as described in Eq. [\(9.4\)](#page-11-1), changes sign in the case of $N = 2$ at the point where the Wilson ratio takes the value $K = 1/\sqrt{2}$, while the sign remains positive for $N \geq 4$. This sign change is due to the wide variation of $\tilde{K}^2/(N-1)$ for $N=2$.
Consequently, in the SU(2) case, W_{ϱ}^{MA} exhibits a local minimum at $\epsilon_d/(\pi\Delta) \simeq -0.5$ in Fig. [12\(](#page-11-0)a), resulting in a steeper variation of $(48/\pi^2)C_{\varrho}^{\text{MA}}$ in the valence fluctuation region compared to $\Theta_{\varrho}^{\text{MA}}$. In contrast, in the **3 2 1 0 1 2**

FIG. 12. Coefficients C_{ϱ}^{MA} , W_{ϱ}^{MA} , and $\Theta_{\varrho}^{\text{MA}}$ for the T^2 resistivity of MAs plotted as functions of ϵ_d : (a) $N = 2$, and (b) $N = 4$.

 $SU(4)$ case, W_{ϱ}^{MA} does not exhibit a minimum. The coefficient for $N = 4$ takes the value $(48/\pi^2)C_{\varrho}^{\text{MA}} \rightarrow 2$ in the quarter-filling Kondo regime, which is determined by the two-body part W_{ϱ}^{MA} . The three-body contribution $\Theta_{\varrho}^{\text{MA}}$ vanishes in this region because the derivative $(4T^*)^2|\partial \chi_{\sigma\sigma}/\partial \epsilon_d|$ is significantly suppressed due to strong electron correlations.

$\, {\bf B.} \quad C_\kappa^{\rm MA} \colon \, {\bf order} \; T^3 \; {\bf term \; of} \; \kappa_{\rm MA}$

The low-temperature expansion of the thermal resistivity $1/\kappa_{\text{MA}}$ of magnetic alloys, derived from Eq. [\(3.7\)](#page-3-8), takes the following form for $SU(N)$ Anderson impurity:

$$
\frac{1}{\kappa_{\text{MA}}} = \frac{3e^2}{\pi^2 \sigma_{\text{MA}}^{\text{unit}}} \frac{1}{T} \left[\sin^2 \delta - C_{\kappa}^{\text{MA}} \left(\frac{\pi T}{T^*} \right)^2 + \cdots \right]. \tag{9.9}
$$

In the $T \to 0$ limit, the leading-order terms of electrical and thermal conductivities satisfy the Wiedemann-Franz law: $\kappa_{\text{MA}}/(T\sigma_{\text{MA}}) \rightarrow \pi^2/(3e^2)$. The coefficient C_{κ}^{MA} for the next-to-leading order term of the thermal conductivity can be divided into two-body W_{κ}^{MA} and three-body $\Theta_{\kappa}^{\text{MA}}$ parts:

$$
C_{\kappa}^{\text{MA}} = \frac{7\pi^2}{80} \left(W_{\kappa}^{\text{MA}} + \Theta_{\kappa}^{\text{MA}} \right), \tag{9.10}
$$

$$
W_{\kappa}^{\text{MA}} \equiv \frac{1}{21} \left[32 + \left(11 - \frac{18\widetilde{K}^2}{N - 1} \right) \cos 2\delta \right], \quad (9.11)
$$

$$
\Theta_{\kappa}^{\text{MA}} \equiv \Theta_{\text{I}} + \frac{5}{21} \widetilde{\Theta}_{\mathbb{I}}.
$$
\n(9.12)

In the limit of $\epsilon_d\to +\infty,$ the FL parameters approach the values $\delta \to 0$, $K \to 0$, $\Theta_{\text{I}} \to -2$, and $\Theta_{\text{II}} \to 0$. Thus,

$$
W_{\kappa}^{\text{MA}} \xrightarrow{\epsilon_d \to +\infty} \frac{43}{21}, \qquad \Theta_{\kappa}^{\text{MA}} \xrightarrow{\epsilon_d \to +\infty} -2. \tag{9.13}
$$

In the 1/N-filling Kondo limit $\epsilon_d \to -\infty$, the parameters take the following values: $\delta \to \pi/N$, $K \to 1$, $\Theta_{\text{I}} + \Theta_{\text{II}} \to$

FIG. 13. Coefficients C_{κ}^{MA} , W_{κ}^{MA} , and $\Theta_{\kappa}^{\text{MA}}$ for the T^3 thermal conductivity of MAs plotted as functions of ϵ_d : (a) $N = 2$, and (b) $N = 4$.

0. Thus,

$$
W_{\kappa}^{\text{MA}} \xrightarrow{\epsilon_d \to -\infty} \frac{1}{21} \left[32 + \left(11 - \frac{18}{N - 1} \right) \cos \frac{2\pi}{N} \right], \tag{9.14}
$$

$$
\Theta_{\kappa}^{\text{MA}} \xrightarrow{\epsilon_d \to -\infty} \frac{16}{21} \Theta_{\text{Kond}}^{1/N} . \tag{9.15}
$$

Here, $\Theta_{\text{Kond}}^{1/2} = 0$ for $N = 2$ and $\Theta_{\text{Kond}}^{1/4} = -1.11$ for $N = 4$, as mentioned.

NRG results for C_{κ}^{MA} , W_{κ}^{MA} , and $\Theta_{\kappa}^{\text{MA}}$ are plotted as functions of ϵ_d in Fig. [13.](#page-12-1) In contrast to the coefficient C_{κ}^{QD} for quantum dots, the coefficient C_{ϱ}^{MA} for magnetic alloys does not change sign throughout the entire range of ϵ_d , for both $N = 2$ and $N = 4$. In the SU(2) case, the plateau value of C_{κ}^{MA} in the halffilling Kondo regime is determined by the two-body part W_{κ}^{MA} , since the three-body part $\Theta_{\kappa}^{\text{MA}}$ vanishes in this case due to electron-hole symmetry. Note that the prefactor $(11 - \frac{18\tilde{K}^2}{N-1})$ for the cos 2δ term in W_{κ}^{MA} , as described in Eq. (9.11) , changes sign for $N = 2$ at the point where the Wilson ratio reaches $\tilde{K} = \sqrt{11/18}$, while this does not occur for $N = 4$. The sign change of this prefactor causes the dip that appears in W_{κ}^{MA} at $\epsilon_d/(\pi\Delta) \simeq -0.6$ in the SU(2) case, and it leads to a steep variation of C_{κ}^{MA} near $\epsilon_d/(\pi\Delta) \simeq -0.3$, as shown in Fig. [13\(](#page-12-1)a). In the SU(4) case, the coefficient C_{κ}^{MA} exhibits a positive plateau structure in the quarter-filling Kondo regime, which is determined by competitive contributions of W_{κ}^{MA} and $\Theta_{\kappa}^{\text{MA}}$. Figure [13\(](#page-12-1)b) also shows that C_{κ}^{MA} for SU(4) magnetic alloys takes the opposite sign compared to C_{κ}^{QD} for quantum dot, described in Fig. [11\(](#page-10-1)b), over the entire filling range $0 < N_d < 1$ in the strong interaction limit $U \to \infty$.

X. SUMMARY

We have studied low-energy transport through the $SU(N)$ Anderson impurity model for quantum dots and magnetic alloys in the strong coupling limit $U \to \infty$ over a wide range of impurity electron filling $0 < N_d < 1$, across the $1/N$ -filling Kondo and valence fluctuation

regimes. Our analysis is based on the latest version of Fermi liquid theory, which reveals the essential role of the three-body correction in completely describing the next-to-leading leading order terms of the transport coefficients. The three-body correlation functions have been calculated for the $SU(2)$ and $SU(4)$ impurities using the NRG approach.

In the quarter-filling Kondo regime, $\epsilon_d \rightarrow -\infty$ for the SU(4) case, the three independent components of the three-body correlation functions, Θ_{I} , $-\Theta_{II}$, and Θ_{III} , converge to a single universal value $\Theta_{\text{Kond}}^{1/4} = -1.11$, which agrees with the analytical value obtained by Mora et al. [\[44\]](#page-16-7) for the corresponding function in the SU(4) Kondo model. However, outside the Kondo regime, such as in the valence fluctuation regime, these three components take different values and contribute distinctly to the nextto-leading order terms of the transport coefficients.

It has also demonstrated that these three-body correlations couple strongly to the tunneling asymmetry $\gamma_{\text{dif}} = (\Gamma_L - \Gamma_R)/(\Gamma_L + \Gamma_R)$ between quantum dots and reservoirs, significantly affecting the order $(eV)^3$ component of nonlinear current through the quarter-filling Kondo state. The order $|eV|^3$ current noise of an SU(4) quantum dot exhibits quite different behavior from that of SU(2). While the coefficient C_S changes sign in the valence fluctuation regime in the SU(2) case even in $U \to \infty$ limit, it remains positive in the SU(4) case due to the competing contributions of two-body W_S and three-body Θ_S correlations.

We have also further examined the next-to-leading order terms of thermoelectric transport coefficients for both quantum dots and magnetic alloys, previously analyzed at finite U [\[58\]](#page-16-10). In contrast to the coefficients C_T and C_{κ}^{QD} , which correspond to the T²-conductance and T³thermal conductance of quantum dots, the coefficients C_{ϱ}^{MA} and C_{κ}^{MA} , defined with respect to electrical and thermal resistivities of magnetic alloys, do not change sign throughout the entire range of impurity electron filling. For $SU(2)$ magnetic alloys, these coefficients exhibit a steep variation in the valence fluctuation region as the occupation number increases toward the Kondo regime. This behavior is caused by the wide variation range of the Wilson ratio R for $N = 2$ and does not occur for $N > 4$.

The three body correlations can experimentally be determined by measuring the coefficients C's for the next leading order terms. The experimental values obtained can then be used to infer the behaviors of other unmeasured transport coefficients. Our results also suggest that all the independent components of $SU(N)$ quantum dots can be determined separately if the coefficient $C_V^{(3)}$ $V^{(3)}$ for the order $(eV)^3$ nonlinear current is measured while varying the tunneling and bias asymmetries.

Appendix A: Higher-order Fermi liquid relations

Here, we provide a brief overview of the microscopic Fermi liquid theory for the Anderson impurity model, including recent developments. The Fermi liquid behavior of quantum impurity systems reflects the low-energy asymptotic form of the retarded Green's function defined in Eq. [\(2.15\)](#page-2-7), which can also be expressed in the following form:

$$
G_{\sigma}^{r}(\omega) = \frac{1}{\omega - \epsilon_{d\sigma} + i\Delta - \Sigma_{\sigma}^{r}(\omega)}.
$$
 (A1)

The phase shift δ_{σ} is given by the argument of the Green's function in the complex plane, $G_{\sigma}^{r}(0) = - |G_{\sigma}^{r}(0)| e^{i\delta_{\sigma}},$ at $\omega = T = eV = 0$. It plays a primary role in the groundstate properties through the Friedel sum rule $\langle n_{d\sigma}\rangle\xrightarrow{T\to0}$ δ_{σ}/π [\[11\]](#page-15-10), e.g., the spectral weight of impurity levels at the Fermi level is given by

$$
\rho_{d\sigma} \equiv \rho_{d\sigma}(0) = \frac{\sin^2 \delta_{\sigma}}{\pi \Delta}, \qquad (A2)
$$

where $\rho_{d\sigma}(\omega) \equiv A_{\sigma}(\omega)\Big|_{T=eV=0}$ and $A_{\sigma}(\omega)$ is the nonequilibrium spectral function defined in Eq. [\(2.16\)](#page-2-8).

The contributions of low-energy excitations can be deduced from the equilibrium self-energy $\Sigma_{\text{eq},\sigma}^r(\omega) \equiv$ $\sum_{\sigma}^r(\omega)|_{T=eV=0}$, by expanding it step-by-step around the Fermi energy $\omega = 0$. The terms up to order ω determine the structure of the renormalized resonance state, as

$$
G_{\sigma}^{r}(\omega) \simeq \frac{z_{\sigma}}{\omega - \tilde{\epsilon}_{d\sigma} + i\tilde{\Delta}_{\sigma}}, \qquad (A3)
$$

where the renormalized parameters are defined by

$$
\frac{1}{z_{\sigma}} \equiv 1 - \left. \frac{\partial \Sigma_{\text{eq},\sigma}^{r}(\omega)}{\partial \omega} \right|_{\omega=0}, \tag{A4}
$$

$$
\widetilde{\epsilon}_{d\sigma} \equiv z_{\sigma} \left[\epsilon_{d\sigma} + \Sigma_{\text{eq},\sigma}^{r}(0) \right], \qquad \widetilde{\Delta}_{\sigma} \equiv z_{\sigma} \Delta. \quad (A5)
$$

The Ward identities [\[9](#page-15-9)[–12\]](#page-15-7), which reflect the current conservation described in Eq. [\(2.5\)](#page-1-3) [\[55\]](#page-16-26), can be expressed, at $T = eV = 0$, as a relation between the causal self-energy $\Sigma_{\text{eq},\sigma}^{-}(\omega)$ and the vertex function $\Gamma_{\sigma\sigma';\sigma'\sigma}^{--,--}(\omega,\omega';\omega',\omega),$ within the standard zero-temperature formalism:

$$
\delta_{\sigma\sigma'}\frac{\partial \Sigma_{\text{eq},\sigma}^{-}(\omega)}{\partial \omega} + \frac{\partial \Sigma_{\text{eq},\sigma}^{-}(\omega)}{\partial \epsilon_{d\sigma'}} = -\Gamma_{\sigma\sigma';\sigma'\sigma}^{-,-;-}(\omega,0;0,\omega)\,\rho_{d\sigma'}.
$$
\n(A6)

Note that $\Sigma_{\text{eq},\sigma}^{--}(\omega) = \Sigma_{\text{eq},\sigma}^r(\omega) \theta(\omega) + \left\{ \Sigma_{\text{eq},\sigma}^r(\omega) \right\}^* \theta(-\omega),$ with $\theta(\omega)$ the Heaviside step function. Since the vertex function for $\sigma = \sigma'$ vanishes at zero frequencies $\omega = \omega'$ $0, as$

$$
\Gamma_{\sigma\sigma;\sigma\sigma}^{-,-;-}(0,0;0,0) = 0, \qquad (A7)
$$

the renormalization factor z_{σ} and the derivative $\partial \Sigma_{\text{eq},\sigma}^r(0)/\partial \epsilon_{d\sigma}$ are related to each other through Eq. [\(A6\)](#page-13-3) [\[12\]](#page-15-7):

$$
\frac{1}{z_{\sigma}} = \widetilde{\chi}_{\sigma\sigma} , \qquad \widetilde{\chi}_{\sigma\sigma'} \equiv \delta_{\sigma\sigma'} + \frac{\partial \Sigma_{\text{eq},\sigma}^r(0)}{\partial \epsilon_{d\sigma'}} . \tag{A8}
$$

The coefficient $\tilde{\chi}_{\sigma\sigma'}$ determines the extent to which the susceptibility $\chi_{\sigma\sigma'}$ is enhanced at $T=0$ by the vertex correction, or the residual interaction between quasiparticles [\[86\]](#page-17-2), i.e.,

$$
\chi_{\sigma\sigma'} = -\frac{\partial \langle n_{d\sigma} \rangle}{\partial \epsilon_{d\sigma'}} \xrightarrow{T \to 0} \rho_{d\sigma} \widetilde{\chi}_{\sigma\sigma'}.
$$
 (A9)

The derivative of $\rho_{d\sigma}(\omega)$ also contributes to the lowenergy transport and is related to the susceptibility by using Eq. $(A8)$, as

$$
\rho'_{d\sigma} \equiv \frac{\partial \rho_{d\sigma}(\omega)}{\partial \omega}\bigg|_{\omega=0} = -\frac{\partial \rho_{d\sigma}}{\partial \epsilon_{d\sigma}} = \frac{\chi_{\sigma\sigma}}{\Delta} \sin 2\delta_{\sigma}.
$$
 (A10)

It has been recently clarified that the vertex function for $\sigma = \sigma'$ also has the following property [\[48,](#page-16-32) [49\]](#page-16-33), in addition to Eq. [\(A7\)](#page-13-5):

$$
\frac{\partial}{\partial \omega} \text{Re} \,\Gamma^{-,-;-}_{\sigma\sigma;\sigma\sigma}(\omega,0;0,\omega) \bigg|_{\omega \to 0} = 0. \tag{A11}
$$

This property indicates that the real part of $\Gamma_{\sigma\sigma;\sigma\sigma}^{--,-}(\omega,0;0,\omega)$ does not contain a linear term in ω . Based on this and the Ward identity given in Eq. [\(A6\)](#page-13-3), the order ω^2 real part of the self-energy has been shown to be expressed in terms of the derivative of the susceptibility, or the three-body correlation function [\[47–](#page-16-34)[50\]](#page-16-8):

$$
\frac{\partial^2}{\partial \omega^2} \text{Re} \Sigma_{\text{eq},\sigma}^r(\omega) \Big|_{\omega \to 0} = \frac{\partial^2 \Sigma_{\text{eq},\sigma}^r(0)}{\partial \epsilon_{d\sigma}^2} = \frac{\partial \widetilde{\chi}_{\sigma\sigma}}{\partial \epsilon_{d\sigma}}. \quad (A12)
$$

Furthermore, from Eqs. [\(A6\)](#page-13-3), [\(A7\)](#page-13-5), and [\(A11\)](#page-13-6), the vertex function $\Gamma_{\sigma\sigma';\sigma'\sigma}^{--,--}(\omega,\omega';\omega',\omega)$ can be exactly deduced up to linear-order terms in ω and ω' at $T = eV = 0$ [\[49,](#page-16-33) [50,](#page-16-8) [55\]](#page-16-26). The result takes the following form, including the imaginary part, which is known to exhibit nonanalytic $|\omega - \omega'|$ and $|\omega + \omega'|$ dependences [\[10–](#page-15-14)[12,](#page-15-7) [32\]](#page-16-35): the diagonal components $(\sigma = \sigma')$ are given by

$$
\Gamma^{-,-;-}_{\sigma\sigma;\sigma\sigma}(\omega,\omega';\omega',\omega)\,\rho_{d\sigma}^2 = i\pi \sum_{\sigma''(\neq\sigma)} \chi_{\sigma\sigma''}^2 |\omega - \omega'| + \cdots,
$$
\n(A13)

and the off-diagonal components $(\sigma \neq \sigma')$ are

$$
\Gamma_{\sigma\sigma';\sigma'\sigma}^{-;--;--}(\omega,\omega';\omega',\omega)\rho_{d\sigma}\rho_{d\sigma'}
$$
\n
$$
= -\chi_{\sigma\sigma'} + \rho_{d\sigma} \frac{\partial \widetilde{\chi}_{\sigma\sigma'}}{\partial \epsilon_{d\sigma}} \omega + \rho_{d\sigma'} \frac{\partial \widetilde{\chi}_{\sigma'\sigma}}{\partial \epsilon_{d\sigma'}} \omega'
$$
\n
$$
+ i\pi \chi_{\sigma\sigma'}^2 \left(|\omega - \omega'| - |\omega + \omega'| \right) + \cdots. \quad (A14)
$$

The order ω^2 imaginary part of the self-energy has been derived through Eqs. $(A6)$ and $(A13)$ [\[10–](#page-15-14)[12\]](#page-15-7):

$$
\frac{\partial^2}{\partial \omega^2} \operatorname{Im} \Sigma_{\text{eq},\sigma}^r(\omega) \bigg|_{\omega \to 0} = -\frac{\pi}{\rho_{d\sigma}} \sum_{\sigma''(\neq \sigma)} \chi_{\sigma\sigma''}^2. \quad \text{(A15)}
$$

The order T^2 term of the retarded self-energy $\Sigma^r_{\sigma}(0)$ can also be deduced from these asymptotic forms of the vertex function [\[49\]](#page-16-33), by rewriting the proof provided by Yamada in Ref. [10](#page-15-14) in the following form, at $eV = 0$,

$$
\Sigma_{\sigma}^{r}(0) - \Sigma_{\sigma}^{r}(0)|_{T=0} = \frac{(\pi T)^{2}}{6} \lim_{\omega \to 0^{+}} \Psi_{\sigma}^{-1}(\omega) + \cdots,
$$
\n(A16)

$$
\Psi_{\sigma}^{--}(\omega) \equiv \lim_{\omega' \to 0} \frac{\partial}{\partial \omega'} \sum_{\sigma'} \Gamma_{\sigma \sigma'; \sigma' \sigma}^{--;---}(\omega, \omega'; \omega', \omega) \rho_{d \sigma'}(\omega') .
$$
\n(A17)

The right-hand side of Eq. [\(A17\)](#page-14-1) can be calculated by using the low-energy asymptotic forms of the vertex func-tion given in Eqs. [\(A13\)](#page-13-7) and [\(A14\)](#page-14-2) for finite ω , and then taking the limit $\omega \to 0$,

$$
\lim_{\omega \to 0} \Psi_{\sigma}^{--}(\omega) = \frac{1}{\rho_{d\sigma}} \sum_{\sigma'(\neq \sigma)} \left[\frac{\partial \chi_{\sigma\sigma'}}{\partial \epsilon_{d\sigma'}} - i \frac{3\pi}{\rho_{d\sigma}} \chi_{\sigma\sigma'}^2 \operatorname{sgn}(\omega) \right].
$$
\n(A18)

Here, the nonanalytic $sgn(\omega)$ dependence of the imaginary part reflects the branch cuts of $\Gamma^{--;---}_{\sigma\sigma';\sigma'\sigma}(\omega,\omega';\omega',\omega)$ along the lines $\omega - \omega' = 0$ and $\omega + \omega' = 0$ in the frequency plane.

Similarly, the bias dependence of the self-energy can be deduced, up to terms of order $(eV)^2$, from the asymptotic form of the vertex function given in Eqs. [\(A13\)](#page-13-7) and $(A14)$, using the Ward identities obtained at $T = 0$ for

the causal self-energy $\Sigma_{\sigma}^{--}(\omega)$ in the Keldysh formalism [\[32,](#page-16-35) [50\]](#page-16-8):

$$
\left. \frac{\partial \Sigma_{\sigma}^{--}(\omega)}{\partial eV} \right|_{eV=0} = \alpha \sum_{\sigma'} \Gamma^{-,-;-}_{\sigma\sigma';\sigma'\sigma}(\omega,0;0,\omega) \rho_{d\sigma'}, \quad \text{(A19)}
$$

$$
\frac{\partial^2 \Sigma_{\sigma}^{--}(\omega)}{\partial (eV)^2}\Big|_{eV=0} = \frac{\Gamma_L \Gamma_R}{(\Gamma_L + \Gamma_R)^2} \Psi_{\sigma}^{--}(\omega)
$$

$$
-\alpha^2 \left(\frac{\partial}{\partial \omega} + \frac{\partial}{\partial \epsilon_d}\right) \sum_{\sigma'} \Gamma_{\sigma \sigma'; \sigma' \sigma}^{--;-;-}(\omega, 0; 0, \omega) \rho_{d\sigma'}.
$$
(A20)

Here, $\partial/\partial \epsilon_d \equiv \sum_{\sigma'} \partial/\partial \epsilon_{d\sigma''}$, and $\Psi_{\sigma}^{--}(\omega)$ is the correla-tion function defined in Eq. [\(A17\)](#page-14-1). The order ωeV term of the self-energy follows from Eq. [\(A19\)](#page-14-3):

$$
\lim_{\omega \to 0} \frac{\partial}{\partial \omega} \left[\frac{\partial \Sigma_{\sigma}^{--}(\omega)}{\partial (eV)} \right]_{eV=0}
$$
\n
$$
= \alpha \sum_{\sigma'(\neq \sigma)} \left[\frac{\partial \widetilde{\chi}_{\sigma \sigma'}}{\partial \epsilon_{d\sigma}} + i \frac{\pi}{\rho_{d\sigma}} \chi^2_{\sigma \sigma'} \operatorname{sgn}(\omega) \right]. \tag{A21}
$$

The second term in the right-hand side of Eq. [\(A20\)](#page-14-4) can also be expressed in the following form, at $\omega \to 0$,

$$
\lim_{\omega \to 0} \left(\frac{\partial}{\partial \omega} + \frac{\partial}{\partial \epsilon_d} \right) \sum_{\sigma'} \Gamma^{-\frac{1}{\sigma \sigma'}; \sigma' \sigma}_{\sigma \sigma' ; \sigma' \sigma} (\omega, 0; 0, \omega) \rho_{d \sigma'}
$$
\n
$$
= \sum_{\sigma' (\neq \sigma)} \left[- \sum_{\sigma'' (\neq \sigma)} \frac{\partial \widetilde{\chi}_{\sigma \sigma'}}{\partial \epsilon_{d \sigma''}} + i \frac{\pi}{\rho_{d \sigma}} \chi^2_{\sigma \sigma'} \operatorname{sgn}(\omega) \right]. \tag{A22}
$$

Note that α is defined such that $\alpha eV \equiv (\Gamma_L \mu_L +$ $\Gamma_R \mu_R)/(\Gamma_L + \Gamma_R)$, i.e.,

$$
\alpha \equiv \frac{\alpha_L \Gamma_L - \alpha_R \Gamma_R}{\Gamma_L + \Gamma_R} = \frac{1}{2} \Big(\alpha_{\text{dif}} + \gamma_{\text{dif}} \Big) \,. \tag{A23}
$$

This parameter α arises in nonequilibrium properties when there is tunneling asymmetry, bias asymmetry, or both [see Eqs. [\(2.13\)](#page-2-9) and [\(2.14\)](#page-2-10) for the definitions of γ_{dif} and α_{dif} .

Consequently, the retarded self-energy $\Sigma^r_{\sigma}(\omega)$ has been exactly obtained up to terms of order ω^2 , T^2 , and $(eV)^2$:

$$
\operatorname{Im} \Sigma_{\sigma}^{r}(\omega) = -\frac{\pi}{2} \frac{1}{\rho_{d\sigma}} \sum_{\sigma'(\neq \sigma)} \chi_{\sigma\sigma'}^{2} \left[(\omega - \alpha eV)^{2} + \frac{3\Gamma_{L}\Gamma_{R}}{(\Gamma_{L} + \Gamma_{R})^{2}} (eV)^{2} + (\pi T)^{2} \right] + \cdots, \tag{A24}
$$

16

$$
\epsilon_{d\sigma} + \text{Re}\,\Sigma_{\sigma}^{r}(\omega) = \Delta \cot \delta_{\sigma} - \sum_{\sigma'(\neq \sigma)} \widetilde{\chi}_{\sigma\sigma'} \,\alpha \, eV + (1 - \widetilde{\chi}_{\sigma\sigma})\,\omega + \frac{1}{6} \frac{1}{\rho_{d\sigma}} \sum_{\sigma'(\neq \sigma)} \frac{\partial \chi_{\sigma\sigma'}}{\partial \epsilon_{d\sigma'}} \left[\frac{3\Gamma_{L}\Gamma_{R}}{(\Gamma_{L} + \Gamma_{R})^{2}} (eV)^{2} + (\pi T)^{2} \right] + \frac{1}{2} \frac{\partial \widetilde{\chi}_{\sigma\sigma}}{\partial \epsilon_{d\sigma}} \,\omega^{2} + \sum_{\sigma'(\neq \sigma)} \frac{\partial \widetilde{\chi}_{\sigma\sigma'}}{\partial \epsilon_{d\sigma}} \,\alpha \, eV\omega + \frac{1}{2} \sum_{\sigma'(\neq \sigma)} \sum_{\sigma''(\neq \sigma)} \frac{\partial \widetilde{\chi}_{\sigma\sigma'}}{\partial \epsilon_{d\sigma''}} \,\alpha^{2} (eV)^{2} + \cdots
$$
 (A25)

In order to investigate the order $|eV|^3$ nonlinear noise, it is necessary to calculate the vertex corrections in the Keldysh formalism exactly up to terms of order $|eV|$ as well. This has been carried out in Ref. [55](#page-16-26) to derive the formulas given in Eqs. (7.1) – (7.4) .

Appendix B: NRG procedures

We have peformed NRG calculations by dividing the N conduction channels into $N/2$ pairs and using the $SU(2)$ spin and $U(1)$ charge symmetries for each pair. The discretization parameter Λ and the number of retained lowlying excited states N_{trunc} are chosen as $(\Lambda, N_{\text{trunc}})$ = $(2,4000)$ for $N = 2$ and $(\Lambda, N_{\text{trunc}}) = (6,10000)$ for $N = 4$. Note that the SU(4) symmetry is preserved in our iteration scheme because the truncation of higher energy states is performed after all new states from these two pairs are added.

In order to calculate $\chi_B^{[3]}$ as defined in Eq. [\(4.11\)](#page-3-9), we introduced a small external potential $\epsilon_{sp,k}$ that depends on the channel index $k = 1, 2, ..., N/2$ and shifts the impurity level from ϵ_d . Specifically, for $N = 4$, this potential is applied in a way equivalent to a local Zeeman field: $\epsilon_{sp,1} = -b$ and $\epsilon_{sp,2} = b$. We then deduced $\chi_B^{[3]}$ from the derivatives of the susceptibilities with respect
from the derivatives of the susceptibilities with respect

to b.

Appendix C: Three-body correlations for the 1/N-filling Kondo state

We briefly describe here the relation between the dimensionless three-body correlation function and the parameters α_1 and α_2 introduced by Mota *el al.* for the $SU(N)$ Kondo model in Refs. [44](#page-16-7) and [45.](#page-16-16) In the strong-interaction limit, their notation corresponds to ours as follows: $\alpha_1/(\pi T_K) \Leftrightarrow \chi_{\sigma\sigma}$, and $\alpha_2/(\pi T_K)^2 \Leftrightarrow$ $-\chi_{\sigma\sigma\sigma}^{[3]}$ (2π). They showed that the ratio of their parameters, α_2/α_1^2 , can be determined analytically using the Bethe ansatz solution [\[87\]](#page-17-3). Specifically, for the $SU(N)$ Kondo state with a single impurity electron, i.e., $\delta \to \pi/N$, which is realized in the $\epsilon_d \to -\infty$ limit of the infinite-U Anderson model, the three-body correlation Θ_{I} approaches this ratio, as

$$
\Theta_{\text{Kond}}^{1/N} \equiv \lim_{\epsilon_d \to -\infty} \Theta_{\text{I}} = -\frac{\alpha_2}{\alpha_1^2} \sin \frac{2\pi}{N}, \qquad \text{(C1)}
$$

$$
\frac{\alpha_2}{\alpha_1^2} = \frac{N-2}{N-1} \frac{\Gamma\left(\frac{1}{N}\right)}{\sqrt{\pi} \Gamma\left(\frac{1}{2} + \frac{1}{N}\right)},\tag{C2}
$$

where $\Gamma(x)$ is the Gamma function. For $N = 4$, it takes the value $\Theta_{\text{Kond}}^{1/4} = -1.1128 \cdots$.
