SUMS OF S-UNITS IN X-COORDINATES OF PELL EQUATIONS

PARVATHI S NAIR AND S. S. ROUT

ABSTRACT. Let S be a fixed set of primes and let $(X_l)_{l>1}$ be the X-coordinates of the positive integer solutions (X, Y) of the Pell equation $\overline{X^2} - dY^2 = 1$ corresponding to a non-square integer $d > 1$. We show that there are only a finite number of nonsquare integers $d > 1$ such that there are at least two different elements of the sequence $(X_l)_{l\geq 1}$ that can be represented as a sum of S-units with a fixed number of terms. Furthermore, we solve explicitly a particular case in which two of the X-coordinates are product of power of two and power of three.

1. INTRODUCTION

The problem of finding specific terms of a linear recurrence sequence of some particular form has a very rich history. Peth $\ddot{\text{o}}$ [\[18\]](#page-13-0) and Shorey-Stewart [\[21\]](#page-13-1) independently studied the perfect powers in a non-degenerate binary recurrence sequence. In particular, they have considered the Diophantine equation

$$
U_n = x^z \tag{1}
$$

in integers n, x, z with $z \geq 2$, where $(U_n)_{n>0}$ is a non-degenerate binary recurrence sequence and proved under certain natural assumptions that [\(1\)](#page-0-0) contain only finitely many perfect powers. For example, Fibonacci and Lucas numbers, respectively, of the form x^z , with $z > 1$ has been recently proved by Bugeaud et al. [\[5\]](#page-12-0). Pethő [\[19\]](#page-13-2) proved that there are no non-trivial perfect powers in Pell sequence (see also $[7]$). Pethő and Tichy [\[20\]](#page-13-3) proved that there are only finitely many Fibonacci numbers of the form $p^a + p^b + p^c$, with prime p and integers $a > b > c \ge 0$. Marques and Togbé [\[16\]](#page-13-4) found all Fibonacci and Lucas numbers of the form $2^a + 3^b + 5^c$ under the condition that $c \geq \max\{a, b\} \geq 0.$

Recently, Bertók et al., $[3]$ under some mild assumptions gave finiteness result for the solutions of the Diophantine equation

$$
U_n = b_1 p_1^{z_1} + \dots + b_s p_s^{z_s}
$$

in non-negative integers z_1, \ldots, z_s and n, where $(U_n)_{n>0}$ is a binary non-degenerate recurrence sequence of positive discriminant, p_1, \ldots, p_s are given primes and b_1, \ldots, b_s are fixed integers.

Diophantine equations combining both S-units and recurrence sequences has been well studied by many authors (see $[2, 3, 10, 13]$ $[2, 3, 10, 13]$ $[2, 3, 10, 13]$ $[2, 3, 10, 13]$). Suppose S is the set of distinct primes p_1, \ldots, p_l . Then a rational integer z is an S-unit if z can be written as

$$
z = \pm p_1^{e_1} \cdots p_l^{e_l},\tag{3}
$$

where e_1, \ldots, e_l are non-negative integers and we denote the set of S-units by \mathcal{U}_S . Let $(U_n)_{n\geq 0}$ be a recurrence sequence of order k with $k \geq 2$. Bérczes et al. [\[2\]](#page-12-3) considered the equation

$$
U_n = z_1 + \dots + z_r,\tag{4}
$$

with some arbitrary but fixed $r \geq 1$, in unknown $n \geq 0$ and $z_1, \ldots, z_r \in \mathcal{U}_S$ and establish finiteness results for the solutions of [\(4\)](#page-1-0).

Let d, t be nonzero integers with $d > 1$ square-free. Consider the Pell equation

$$
x^2 - dy^2 = 1\tag{5}
$$

in integers x, y . Recently, several mathematicians have investigated the following type of problem related to solution sets (i.e., X and Y -coordinates) of Pell equation [\(5\)](#page-1-1). Assume that $\mathbb{U} := (U_n)_{n>0}$ is some interesting sequence of positive integers and $\{(X_m, Y_m)\}_{m\geq 1}$ are sequence of solutions of Pell equation [\(5\)](#page-1-1). What can one say about the number of solutions of the containment $X_m \in \mathbb{U}$ for a generic d? What about the number of solutions of the containment $Y_m \in \mathbb{U}$? For most of the binary recurrent sequences(Fibonacci numbers [\[4,](#page-12-5) [15\]](#page-13-6), tribonacci numbers [\[14\]](#page-13-7), rep-digits in some given integer base $b \geq 2$ [\[8,](#page-12-6) [11,](#page-12-7) [12\]](#page-12-8)), the equation $X_m \in \mathbb{U}$ has at most one positive integer solution m for any given d except for finitely many values of d. Erazo et al., [\[10\]](#page-12-4) showed under certain conditions that there are only a finite number non-square integers $d > 1$ such that there are at least two different elements of the sequence $(X_m)_{m\geq 1}$ that can be represented as a linear combination of prime powers with fixed primes, i.e.,

$$
X_m = c_1 p_1^{n_1} + \cdots + c_s p_s^{n_s}.
$$

In this paper, we extend this result to sums of S-units. In particular, we will prove that there are only a finite number non-square integers $d > 1$ such that there are at least two different elements of the sequence $(X_m)_{m>1}$ that can be represented as a sum of S-units. Firstly, we prove the general case when elements of the sequence $(X_m)_{m>1}$ equal to sum of S-units, that is,

$$
X_l = z_1 + \dots + z_r,\tag{6}
$$

where $z_1, \ldots, z_r \in \mathcal{U}_S$ and l are positive integers. Then in next result, we solve a particular case of [\(6\)](#page-1-2) with $S = \{2, 3\}.$

2. Notation and Main Results

Let $d > 1$ be an integer which is not a square. The Pell equation

$$
X^2 - dY^2 = 1,\tag{7}
$$

where $X, Y \in \mathbb{Z}_{>0}$ has infinitely many positive integer solutions (X, Y) and have the form

$$
X + Y\sqrt{d} = X_l + Y_l\sqrt{d} = (X_1 + Y_1\sqrt{d})^l
$$

for some $k \in \mathbb{Z}_{>0}$ and (X_1, Y_1) is the smallest positive integer solution of [\(7\)](#page-2-0). The sequence $(X_l)_{l\geq 1}$ is a binary recurrence sequence satisfying the recurrence relation

$$
X_l = 2X_1 X_{l-1} - X_{l-2}
$$
\n(8)

for all $l \geq 2$. Setting

$$
\gamma := X_1 + Y_1 \sqrt{d} \text{ and } \eta := X_1 - Y_1 \sqrt{d} = \gamma^{-1},
$$
\n(9)

so $\gamma \cdot \eta = X_1^2 - dY_1^2 = 1$. The Binet formula for X_l and Y_l are

$$
X_l = \frac{\gamma^l + \eta^l}{2} \quad \text{and} \quad Y_l = \frac{\gamma^l - \eta^l}{2\sqrt{d}} \tag{10}
$$

holds for all non-negative integers l. Let $s \in \mathbb{Z}_{>0}$ be fixed. We are interested to determine for which positive integers $d > 1$, the sequence $(X_l)_{l\geq 1}$ of X-coordinates of [\(7\)](#page-2-0) has at least two different terms that can be represented as $\overline{in}(6)$. By denoting $z_i = p_1^{n_{i1}} \cdots p_s^{n_{is}}$ for all $1 \leq i \leq r$, we write [\(6\)](#page-1-2) as

$$
X_l = p_1^{n_{11}} p_2^{n_{12}} \cdots p_s^{n_{1s}} + \cdots + p_1^{n_{r1}} p_2^{n_{r2}} \cdots p_s^{n_{rs}}.
$$
\n(11)

such that,

$$
n_{rs} = \max_{\substack{1 \le i \le r \\ 1 \le j \le s}} \{n_{ij}\}.
$$
\n
$$
(12)
$$

Now we are ready to state our main theorem.

Theorem 2.1. Let s be a fixed positive integer. Let $p_1 \leq \cdots \leq p_s$ be fixed primes with p_s odd. Let X_l be the X-coordinate of the Pell equation [\(7\)](#page-2-0) with $d > 1$ non-square. Let $\epsilon > 0$ be arbitrary. Consider [\(6\)](#page-1-2) in $l \geq 1$ and z_1, \ldots, z_r satisfying $|z_i|^{1+\epsilon} < |z_r|, (i =$ $1, \ldots, r-1$ and [\(12\)](#page-2-1). Let T_d be the set of solutions (l, z_1, \ldots, z_r) of [\(6\)](#page-1-2). Then there exists effectively computable constants $c_8(s)$ and $c_9(s)$ depend only on the parameters $s, p_s, r \text{ and } \epsilon \text{ such that}$

(i) if $d < p_s^{2c_8}r^2$, then $\#T_d \le c_9(s)$, (ii) if $d \geq p_s^{2cs}r^2$, then $\#T_d \leq 1$.

Note that Theorem [2.1](#page-2-2) extends the corresponding statement from [\[10\]](#page-12-4) to this more general situation. Our next theorem illustrates Theorem [2.1,](#page-2-2) in which we explicitly solve [\(11\)](#page-2-3) for the case $r = 1$, $s = 2$ and $S = \{2, 3\}$.

$$
X_l = 2^{n_1} 3^{n_2}, \qquad n_1 \le n_2 \tag{13}
$$

has at least two positive integer solutions.

3. Auxiliary results

In this section, we will prove some preliminary results to prove main theorems.

Lemma 3.1. Let $\gamma > 0$ be the fundamental solution of [\(7\)](#page-2-0) for $d > 1$ non-square. Then

$$
\left(\frac{1}{1+\sqrt{2}}\right)\gamma^{l} \le X_{l} \le (2-\sqrt{2})\gamma^{l}, \quad \text{for all } l \ge 1. \tag{14}
$$

Proof. See Lemma 1 in [\[10\]](#page-12-4).

Let α be an algebraic number of degree d. Then the *logarithmic height* of the algebraic number α is given by

$$
h(\alpha) = \frac{1}{d} \left(\log |a| + \sum_{i=1}^{d} \log \max\{1, |\alpha^{(i)}|\} \right),\,
$$

where a is the leading coefficient of the minimal polynomial of α over $\mathbb Z$ and the $\alpha^{(i)}$'s are the conjugates of α in C. In particular, if $z = p/q$ is a rational number with $gcd(p, q) = 1$, and $q > 0$ then $h(z) = \log \max\{|p|, q\}.$

To prove Theorem [2.1,](#page-2-2) we use a lower bound of linear forms in logarithms to bound the index l, z_1, \ldots, z_s appearing in [\(6\)](#page-1-2). In particular, we need the following result due to Matveev [\[17\]](#page-13-8).

Lemma 3.2 (Matveev's Theorem). Let η_1, \ldots, η_t be real algebraic numbers and let d_1, \ldots, d_t be rational integers. Let $d_{\mathbb{L}}$ be the degree of the number field $\mathbb{L} = \mathbb{Q}(\eta_1, \ldots, \eta_t)$ over Q. Let A_i be real numbers satisfying

 $A_j \ge \max\{d_{\mathbb{L}}h(\eta_j), |\log \eta_j|, 0.16\}, \quad j = 1, \ldots, t.$

Assume that $B \ge \max\{|d_1|, \ldots, |d_t|\}$ and $\Lambda := \eta_1^{d_1} \cdots \eta_t^{d_t} - 1$. If $\Lambda \ne 0$, then

$$
|\Lambda| \geq \exp\left(-1.4 \cdot 30^{t+3} \cdot t^{4.5} \cdot d_{\mathbb{L}}^2 (1 + \log d_{\mathbb{L}})(1 + \log B) A_1 \cdots A_t\right).
$$

Lemma 3.3. Let B be a non-negative integer such that $\delta B \le \alpha \log B + \beta$. If $\alpha \ge e\delta$, then

$$
B \le (2/\delta)(\alpha \log(\alpha/\delta) + \beta).
$$

Proof. See [\[6,](#page-12-9) Lemma 12.2.4]

4

We need some more results from the theory of continued fractions. The following result will be useful for the treatment of linear forms in logarithms.

Lemma 3.4. Let τ be an irrational number, M be a positive integer and p_0/q_0 , $p_1/q_1, \ldots$, be all the convergents of the continued fraction $[a_0, a_1, \ldots]$ of τ . Let N be such that $q_N > M$. Then putting $a(M) := \max\{a_t : t = 0, 1, \ldots, N\}$, the inequality

$$
|m\tau - n| > \frac{1}{(a(M) + 2)m}
$$

holds for all pairs (n, m) of integers with $0 < m < M$.

After getting the upper bound of n_2 , which is generally too large, the next step is to reduce it. For this reduction purpose, we use a variant of the Baker–Davenport result [\[1\]](#page-12-10). Here, for a real number x, let $||x|| := \min\{|x - n| : n \in \mathbb{Z}\}\)$ denote the distance from x to the nearest integer.

Lemma 3.5 (See [\[9\]](#page-12-11)). Let τ be an irrational number, M be a positive integer and p/q be a convergent of the continued fraction of τ such that $q > 6M$. Let A, B, μ be some real numbers with $A > 0$ and $B > 1$. Put $\epsilon_1 := ||\mu q|| - M||\tau q||$, then there is no solution to the inequality

$$
|m\tau - n + \mu| < AB^{-k},
$$

in positive integers m, n and k with

$$
m \leq M
$$
 and $k \geq \frac{\log(Aq/\epsilon_1)}{\log B}$.

4. Proof of Theorem [2.1](#page-2-2)

Suppose $1 \leq l_1 < l_2$, such that

$$
X_{l_1} = p_1^{a_{11}} p_2^{a_{12}} \cdots p_s^{a_{1s}} + \cdots + p_1^{a_{r1}} p_2^{a_{r2}} \cdots p_s^{a_{rs}}
$$

and

$$
X_{l_2} = p_1^{b_{11}} p_2^{b_{12}} \cdots p_s^{b_{1s}} + \cdots + p_1^{b_{r1}} p_2^{b_{r2}} \cdots p_s^{b_{rs}}.
$$
 (15)

Denote

$$
(l, n_{11}, \ldots, n_{1s}, n_{21}, \ldots, n_{2s}, \ldots, n_{r1}, \ldots, n_{rs})
$$

= $(l_1, a_{11}, \ldots, a_{1s}, a_{21}, \ldots, a_{2s}, \ldots, a_{r1}, \ldots, a_{rs})$

or

$$
(l, n_{11}, \ldots, n_{1s}, n_{21}, \ldots, n_{2s}, \ldots, n_{r1}, \ldots, n_{rs})
$$

= $(l_2, b_{11}, \ldots, b_{1s}, b_{21}, \ldots, b_{2s}, \ldots, b_{r1}, \ldots, b_{rs}).$

By Lemma [3.1,](#page-3-0)

$$
\frac{\gamma^l}{2.5} < X_l < \gamma^l. \tag{16}
$$

From (11) and (12) , it follows that,

$$
p_s^{n_{rs}} < X_l < r p_s^{sn_{rs}}.\tag{17}
$$

As $(X_l)_{l\geq 1}$ is an increasing sequence,

$$
p_s^{a_{rs}} \le X_{l_1} \le X_{l_2} \le rp_s^{s b_{rs}}
$$

and this implies

$$
a_{rs} \le sb_{rs} + \frac{\log r}{\log p_s}.\tag{18}
$$

From (16) and (17) we get

$$
p_s^{n_{rs}} < \gamma^l < 2.5X_l < 2.5rp_s^{sn_{rs}},
$$

and this further implies,

$$
n_{rs}\log p_s < l\log \gamma < sn_{rs}\log p_s + \log 2.5r.\tag{19}
$$

Thus,

$$
\frac{n_{rs}}{\log \gamma} < \frac{l}{\log p_s} < l. \tag{20}
$$

Since for $\epsilon > 0$, $|z_i|^{1+\epsilon} < |z_r|$, for $i = 1, \ldots, r-1$, then from [\(6\)](#page-1-2) it follows that

$$
X_l| = |z_1 + \dots + z_r| \le (r-1)|z_r|^{\frac{1}{1+\epsilon}} + |z_r| \le r|z_r|,
$$
\n(21)

 $\eta^l \leq \frac{\gamma^{(n_{rs}/\log \gamma)}}{4}$ 4

which implies

$$
|z_r| \ge \frac{|X_l|}{r}.\tag{22}
$$

If
$$
|X_l| \le \frac{\gamma^{(n_{rs}/\log \gamma)}}{4}
$$
, then

$$
\frac{1}{2}\gamma^l < |X_l| = \frac{1}{2}\gamma^l + \frac{1}{2}
$$

 $\overline{}$

i.e.,

$$
\frac{1}{2}\gamma^l < \frac{\gamma^l}{4},
$$

2

which is not true. So assume that,

$$
|X_l| > \frac{\gamma^{(n_{rs}/\log \gamma)}}{4}.\tag{23}
$$

 \lt γ^l 4

We rewrite [\(6\)](#page-1-2) using [\(10\)](#page-2-4) as

$$
\frac{1}{2}\gamma^{l} - z_{r} = z_{1} + \dots + z_{r-1} - \frac{1}{2}\eta^{l}.
$$
\n(24)

Dividing throughout by z_r ,

$$
\left|2^{-1}\gamma^{l}z_{r}^{-1} - 1\right| \leq \left|\frac{\sum_{i=1}^{r-1} z_{i}}{z_{r}}\right| + \left|\frac{\eta^{l}}{2z_{r}}\right|.\tag{25}
$$

Next we will find bounds for each term in the right hand side of [\(25\)](#page-5-1). From (22) and (23) ,

$$
\frac{\sum_{i=1}^{r-1} |z_i|}{|z_r|} \le (r-1) \frac{|z_r|^{\frac{1}{1+\epsilon}}}{|z_r|} \le (r-1) \frac{1}{|z_r|^{\frac{\epsilon}{1+\epsilon}}}
$$

$$
\le (r-1) \frac{(4r)^{\frac{\epsilon}{1+\epsilon}}}{\gamma^{\frac{(n_{rs}/\log \gamma)\epsilon}{1+\epsilon}}} \le c_1(s) \frac{1}{\gamma^{\frac{(n_{rs}/\log \gamma)\epsilon}{1+\epsilon}}},
$$

where $c_1(s) = (r-1)(4r)^{\frac{\epsilon}{1+\epsilon}}$. To find a bound for $\begin{array}{c} \hline \end{array}$ η^l $2z_r$

$$
\left|\frac{\eta^l}{2z_r}\right| < \frac{1}{2} \cdot \frac{4r\eta^l}{\gamma^{(n_{rs}/\log \gamma)}} < 2r \cdot \frac{\eta^l}{\gamma^{(n_{rs}/\log \gamma)}} < 2r \cdot \left(\frac{\eta}{\gamma}\right)^{n_{rs}/\log \gamma}
$$

Substituting these bounds in [\(25\)](#page-5-1),

$$
\left|2^{-1}\gamma^{l}z_{r}^{-1} - 1\right| \leq c_{1}(s)\frac{1}{\gamma^{\frac{(nrs/\log\gamma)\epsilon}{1+\epsilon}}} + 2r \cdot \left(\frac{\eta}{\gamma}\right)^{n_{rs}/\log\gamma}
$$

$$
\leq c_{2}(s) \cdot \max\left\{\frac{1}{\gamma^{\frac{\epsilon}{1+\epsilon}}}, \frac{\eta}{\gamma}\right\}^{n_{rs}/\log\gamma}.
$$
(26)

 $\begin{array}{c} \begin{array}{c} \begin{array}{c} \begin{array}{c} \end{array} \\ \end{array} \\ \begin{array}{c} \end{array} \end{array} \end{array}$,

.

We know that, if $|x-1| < \frac{1}{2}$ $\frac{1}{2}$, then $|\log x| < 2|x-1|$. Set

$$
\Lambda := 2^{-1} \gamma^l z_r^{-1} - 1 \quad \text{and} \quad \Gamma := -\log 2 + l \log \gamma - \log z_r.
$$

Using the fact that $z_r = p_1^{n_{r1}} \cdots p_s^{n_{rs}},$

$$
|\Lambda| = \left|\frac{1}{2}\gamma^l p_1^{-n_{r1}}\cdots p_s^{-n_{r}s} - 1\right|.
$$

If $|\Lambda| = 0$, then $\gamma^l = 2z_r$ is an integer, which is false for any $l \geq 1$. Hence $|\Lambda| \neq 0$. So applying Matveev's theorem (Lemma [3.2\)](#page-3-1), with

 $(\eta_1, d_1) = (2, -1), (\eta_2, d_2) = (\gamma, l), \text{ and } (\eta_{i+2}, d_{i+2}) = (p_i, -n_{ri}) \text{ with } i = 1, \dots, s.$ Furthermore,

$$
d_{\mathbb{L}} = 2
$$
, $h(2) = \log 2$, $h(\gamma) = \frac{1}{2} \log \gamma$, $h(p_j) = \log p_j$, where $j = 1, ..., s$.

We choose A_i 's as follows,

$$
A_1 = 0.16
$$
, $A_2 = \log \gamma$, $A_{i+2} = 2 \log p_i$, with $i = 1, ..., s$.

Since p_s is odd, without loss of generality we assume that $\min\{\gamma, n_{rs}\} \geq 2.5rp_s > 7$. From [\(19\)](#page-5-4),

$$
l < \frac{s n_{rs} \log p_s + \log 2.5r}{\log \gamma}.
$$

Now if $\min\{\gamma, n_{rs}\} = \gamma$, then $2.5rp_s < \gamma$, which implies that, $\log p_s < \log \gamma - \log 2.5r$. Substituting this in above inequality ,

$$
l < \frac{sn_{rs}(\log \gamma - \log 2.5r) + \log 2.5r}{\log \gamma} < sn_{rs}.
$$

If $\min\{\gamma, n_{rs}\} = n_{rs}$, then $n_{rs} < \gamma$, so as in the previous case $l < sn_{rs}$. Hence, in both cases $l < sn_{rs}$. So we can take $B = sn_{rs}$. Applying Matveev's theorem with $t = s + 2$,

$$
\log |\Lambda| > -1.4 \cdot 30^{s+5} (s+2)^{4.5} 2^2 (1+\log 2)(1+\log(s n_{rs}))
$$

0.16($\log \gamma$)(2 $\log p_1$) ··· (2 $\log p_s$)
> $-c_3(s) (\log n_{rs}) (\log \gamma)$. (27)

It is clear that, $\gamma^{\frac{\epsilon}{1+\epsilon}} < \gamma^2$ for $0 < \epsilon < 1$. Now taking logarithm on both sides of [\(26\)](#page-6-0) and comparing with [\(27\)](#page-7-0),

$$
-c_3(s)(\log n_{rs})(\log \gamma) < \log c_2(s) - \left(\frac{\epsilon n_{rs}}{(1+\epsilon)\log \gamma}\right) \log \gamma,
$$

which further gives

$$
n_{rs} < \left(\frac{1+\epsilon}{\epsilon}\right) \left(\log c_2(s) + c_3(s)(\log n_{rs})(\log \gamma)\right) \le c_4(s)(\log n_{rs})(\log \gamma).
$$
\n(28)

This gives an upper bound for n_{rs} in terms of log γ . For $i = 1, 2$ let

$$
\Gamma_1^{(i)} := -\log 2 + l_i \log \gamma - \log(p_1^{m_{r1}} \cdots p_s^{m_{rs}})
$$

= $-\log 2 + l_i \log \gamma - \sum_{k=1}^s m_{rk} \log p_k$.

Note that $m_{rk} = a_{rk}$ or b_{rk} for $k = 1, ..., s$. Next our aim is to eliminate term involving $\log \gamma$ from $\Gamma_1^{(i)}$. For that, consider

$$
\Gamma_2 := l_1 \Gamma_1^{(2)} - l_2 \Gamma_1^{(1)} = (l_2 - l_1) \log 2 + (l_2 - l_1) \sum_{k=1}^s m_{rk} \log p_k.
$$
 (29)

Since $l_1 < l_2$, then from [\(26\)](#page-6-0),

$$
|\Gamma_2| \le l_1 |\Gamma_1^{(2)}| + l_2 |\Gamma_1^{(1)}|
$$

\n
$$
\le l_2 c_2(s) \cdot \max \left\{ \frac{1}{\gamma^{\frac{\epsilon}{1+\epsilon}}}, \frac{\eta}{\gamma} \right\}^{b_{rs}/\log \gamma} + l_2 c_2(s) \cdot \max \left\{ \frac{1}{\gamma^{\frac{\epsilon}{1+\epsilon}}}, \frac{\eta}{\gamma} \right\}^{a_{rs}/\log \gamma}
$$

\n
$$
\le l_2 c_2(s) \cdot \max \left\{ \frac{1}{\gamma^{\frac{\epsilon}{1+\epsilon}}}, \frac{\eta}{\gamma} \right\}^{a_{rs}/\log \gamma} \left(1 + \max \left\{ \frac{1}{\gamma^{\frac{\epsilon}{1+\epsilon}}}, \frac{\eta}{\gamma} \right\}^{b_{rs}/\log \gamma - a_{rs}/\log \gamma} \right) \qquad (30)
$$

\n
$$
\le l_2 c_5(s) \cdot \max \left\{ \frac{1}{\gamma^{\frac{\epsilon}{1+\epsilon}}}, \frac{\eta}{\gamma} \right\}^{a_{rs}/\log \gamma}.
$$

Assume that, $c_5(s) \cdot l_2 \max \left\{ \frac{1}{\sqrt{15}} \right\}$ $\frac{1}{\gamma^{\frac{\epsilon}{1+\epsilon}}}, \frac{\eta}{\gamma}$ γ $\int a_{rs}/\log \gamma$ $<$ 1/2. Otherwise, we can derive a bound which is weaker than the bound with this assumption. Set

$$
|\Lambda_2| := |2^{(l_2 - l_1)} p_1^{n_{r1}(l_2 - l_1)} \cdots p_s^{n_{rs}(l_2 - l_1)} - 1|
$$

= $|e^{\Gamma_2} - 1| < 2|\Gamma_2| < 2c_5(s) \cdot l_2 \max\left\{\frac{1}{\gamma^{\frac{\epsilon}{1+\epsilon}}}, \frac{\eta}{\gamma}\right\}^{a_{rs}/\log \gamma}$ (31)

We will apply Matveev's theorem for Λ_2 with

 $(\eta_1, d_1) := (2, l_2 - l_1), \qquad (\eta_{i+1}, d_{i+1}) := (p_i, n_{ri}(l_2 - l_1)), \text{ where } i = 1, \ldots, s.$ Again, $d_{\mathbb{L}} = 1$, $h(2) = \log 2$, $h(p_i) = \log p_i$, with $i = 1, ..., s$. Choose $A_1 = 2 \log 2, \qquad A_{i+1} = 2 \log p_i, \text{ with } i = 1, \ldots, s.$

Note that $|n_{ri}(l_2-l_1)| \le n_{rs}(l_2+l_1)$ and $l_2 < sn_{rs}$. Here $B \ge \max_{1 \le i \le s} \{|l_2-l_1|, |n_{ri}(l_2-l_1)|\}$. So, we can set $B = 2s(n_{rs})^2$. Applying Matveev's theorem,

$$
\log |\Lambda_2| > -1.4 \cdot 30^{s+4} \cdot (s+1)^{4.5} (1 + \log(2s(n_{rs})^2))(2 \log 2)
$$

$$
(2 \log p_1) \cdots (2 \log p_s)
$$

$$
> -c_6(s) \log n_{rs}.
$$

We have, $\gamma^{\frac{\epsilon}{1+\epsilon}} < \gamma^2$ for $0 < \epsilon < 1$. Now comparing the above inequality with [\(31\)](#page-8-0), we get

$$
-c_6(s) \log n_{rs} < \log(2l_2c_5(s)) - \frac{a_{rs}}{\log \gamma} \log \max \left\{ \gamma^{\frac{\epsilon}{1+\epsilon}}, \gamma^2 \right\}
$$

$$
\leq \log(2l_2c_5(s)) - \frac{a_{rs}}{\log \gamma} \log \gamma^{\frac{\epsilon}{1+\epsilon}}.
$$

i.e.,

$$
\frac{a_{rs}}{\log \gamma} \cdot \frac{\epsilon}{1+\epsilon} \log \gamma < c_6(s) \log n_{rs} + \log(2l_2c_5(s)),
$$

which implies that,

$$
a_{rs} < \left(\frac{1+\epsilon}{\epsilon}\right) \left(\log(2l_2c_5(s)) + c_6(s)\log n_{rs}\right). \tag{32}
$$

Considering [\(28\)](#page-7-1) for $n_{rs} = b_{rs}$,

 $b_{rs} < c_4(s) (\log b_{rs}) (\log \gamma).$

By Lemma [3.3,](#page-3-2)

$$
b_{rs} < 2(c_4(s)\log\gamma \cdot \log(c_4(s)\log\gamma)).\tag{33}
$$

Using [\(19\)](#page-5-4) for $n_{rs} = a_{rs}$ we get,

$$
a_{rs}\log p_s < l_1\log\gamma < sa_{rs}\log p_s + \log 2.5r
$$

and this implies,

$$
\log \gamma < l_1 \log \gamma < s a_{rs} \log p_s + \log 2.5r. \tag{34}
$$

Since $l_2 < sb_{rs}$, so from [\(32\)](#page-8-2) and [\(35\)](#page-9-0) we infer,

$$
a_{rs} < \left(\frac{1+\epsilon}{\epsilon}\right) \left(\log(2sb_{rs}c_5(s)) + c_6(s)\log b_{rs}\right) < \left(\frac{1+\epsilon}{\epsilon}\right) \left(\log(2s2(c_4(s)2a_{rs}s\log p_s \cdot \log(c_4(s)2a_{rs}s\log p_s))c_5(s))\right) < \left(\frac{1+\epsilon}{\epsilon}\right) \left(c_6(s)\log(2(c_4(s)2a_{rs}s\log p_s \cdot \log(c_4(s)2a_{rs}s\log p_s)))\right).
$$

By Lemma [3.3](#page-3-2) ,

 $a_{rs} < c_7(s)$.

Thus [\(34\)](#page-8-3) implies that,

$$
\log \gamma < \mathit{sc}_7(s) \log p_s + \log 2.5r,\tag{36}
$$

where $c_7(s)$ is an effectively computable constant that depends only on s, p_s and ϵ . So,

$$
\log \gamma < \log(p_s^{sc_7(s)} 2.5r),
$$

i.e.,

Since
$$
\gamma > 2\sqrt{d-2}
$$
, then
\n
$$
\gamma < p_s^{sc_7(s)} 2.5r.
$$
\nAlso

Also,

$$
l_2 < b_{rs}s < s2(c_4(s)2c_7(s)s\log p_s \cdot \log(c_4(s)2c_7(s)s\log p_s)) =: c_9(s).
$$

Thus, we conclude that there are only finitely many possibilities for d under the assumption that $\min\{\gamma, n_{rs}\} \geq 2.5rp_s$. If $\min\{\gamma, n_{rs}\} < 2.5rp_s$, then again we can obtain bounds on l, n_{rs} and d. In particular, if $n_{rs} = \min\{\gamma, n_{rs}\} < 2.5rp_s$, then by [\(19\)](#page-5-4), we have upper bounds on $l, \log \gamma$ and then on d. However, if $\gamma = \min\{\gamma, n_{rs}\} < 2.5rp_s$, then there exists an upper bound on d and then on l and n_{rs} . This completes the proof of Theorem [2.1.](#page-2-2)

5. Proof of Theorem [2.2](#page-3-3)

Suppose that for $1 \leq l_1 < l_2$,

$$
X_{l_1} = 2^{a_1} 3^{a_2} \quad \text{and} \quad X_{l_2} = 2^{b_1} 3^{b_2}, \tag{37}
$$

with $a_1 \leq a_2$ and $b_1 \leq b_2$. We denote

$$
(l, n_1, n_2) = (l_1, a_1, a_2)
$$
 or $(l, n_1, n_2) = (l_2, b_1, b_2).$

Assume $n_2 > n_1$. From the proof of Theorem [2.1,](#page-2-2)

$$
3^{n_2} < X_l = 2^{n_1} 3^{n_2} < 3^{2n_2}.\tag{38}
$$

10

Also

$$
3^{a_2} \le X_{l_1} \le X_{l_2} \le 3^{2b_2}
$$

and this implies $a_2 \le 2b_2$. From [\(38\)](#page-9-1) and [\(16\)](#page-4-0), we get $3^{n_2} < \gamma^l < 2.5X_l < 2.5 \cdot 3^{2n_2}$. This gives,

$$
n_2 \log 3 < l \log \gamma < 2n_2 \log 3 + \log 2.5. \tag{39}
$$

.

Using (10) , rewrite (13) as

$$
\frac{\gamma^l}{2^{(n_1+1)}3^{n_2}}-1=\frac{\eta^l}{2^{(n_1+1)}3^{n_2}}
$$

Setting $\Lambda := \gamma^l 2^{-(n_1+1)} 3^{-n_2} - 1$, we get

$$
|\Lambda| \le \left| \frac{\eta^l}{2^{(n_1+1)} 3^{n_2}} \right| \le \frac{1}{3^{n_2}}.\tag{40}
$$

Put

$$
\Gamma = l \log \gamma - (n_1 + 1) \log 2 - n_2 \log 3 \tag{41}
$$

and since $|\Lambda| = |e^{\Gamma} - 1| < \frac{1}{2}$ $\frac{1}{2}$, so $|\Gamma| < 2|\Lambda| < 2 \cdot 3^{-n_2}$. Since γ is not an integer, so $\Lambda \neq 0$. Hence we can use Matveev's theorem with $t = 3$ and

$$
(\eta_1, d_1) = (2, -(n_1 + 1)), \qquad (\eta_2, d_2) = (\gamma, l), \qquad (\eta_3, d_3) = (3, -n_2).
$$

Further, $d_{\mathbb{L}} = 2, h(2) = \log 2, h(\gamma) = \frac{1}{2} \log \gamma, h(3) = \log 3, A_1 = 2 \log 2, A_2 = \log \gamma, A_3 =$ 2 log 3. Assume that $\min\{\gamma, n_2\} \geq 7.5$. Then one can see that $l < 2n_2$. Applying Matveev's theorem ,

$$
\log |\Lambda| > -c_{10} (\log n_2)(\log \gamma) \log 3,
$$

where $c_{10} = 1.33 \cdot 10^{14}$. Comparing above inequality with [\(40\)](#page-10-0), we get

$$
n_2 < c_{11}(\log n_2) \log \gamma, \text{ with } c_{11} = 1.34 \cdot 10^{14}.\tag{42}
$$

To eliminate $\log \gamma$, let

$$
\Gamma_1^{(i)} := -(m_1 + 1) \log 2 - m_2 \log 3 + l_i \log \gamma,
$$

where $m_i = a_i$ or b_i with $i = 1, 2$. Define

$$
\Gamma_2 := l_1 \Gamma_1^{(2)} - l_2 \Gamma_1^{(1)}
$$

= $(l_2 - l_1 + l_2 a_1 - l_1 b_1) \log 2 + (l_2 a_2 - l_1 b_2) \log 3.$ (43)

Then proceeding as in the proof of Theorem [2.1,](#page-2-2) we get

$$
|\Gamma_2| \le c_{12} \cdot l_2 3^{-\frac{a_2}{2}} \quad \text{with } c_{12} = 4,\tag{44}
$$

 $b_2 < 2 \cdot 4c_{11}a_2 \log 3 \cdot \log(4c_{11}a_2 \log 3) < 8.62 \cdot 10^{28}$ and $l_2 < 2b_2 < 17.2 \cdot 10^{28}$. These bounds are very large for a computational search. Our next aim is to reduce these bounds to smaller numbers using Lemma [3.4](#page-4-1) and [3.5.](#page-4-2) From [\(43\)](#page-10-1) and [\(44\)](#page-10-2),

$$
\left|\frac{\log 2}{\log 3} - \frac{(l_1b_2 - l_2a_2)}{l_2(1 + a_1) - l_1(1 + b_1)}\right| \le \frac{c_{12}l_2}{3^{\frac{a_2}{2}} \cdot (l_2(1 + a_1) - l_1(1 + b_1))(\log 3)}
$$

To use Lemma [3.4,](#page-4-1) put $\tau :=$ $\frac{\log 2}{\log 3}$ and $M_1 := 8.62 \cdot 10^{28}$. With the help of Mathematica finding q such that $q > M_1$ as $\tilde{q}_{60} > 8.62 \cdot 10^{28}$ and $a(M_1) = 55$. Now applying Lemma [3.4,](#page-4-1)

$$
3^{\frac{a_2}{2}} < \frac{c_{12}l_2(l_2(1+a_1) - l_1(1+b_1))57}{\log 3} < 1824 \cdot M_1^3,
$$

which implies that,

$$
a_2 < \frac{2\log(1824 \cdot M_1^3)}{\log 3} < 377.55
$$

i.e., $a_2 \leq 377$ and this gives $b_2 < 1.78 \cdot 10^{19}$. To get better bounds repeat this process with new M value. Next put $M_2 = 1.78 \cdot 10^{19}$. Finding the value of q as, $q_{41} > 1.78 \cdot 10^{19}$ and $a(M_2) = 55$. Hence $a_2 \leq 255$ and $b_2 < 1.2 \cdot 10^{19}$. Using Lemma [3.4](#page-4-1) again with $M_3 = 1.2 \cdot 10^{19}$ to get $a_2 \leq 253$. This way will not give any better bounds further. So we will use another method.

Consider the following polynomial with integer coefficients:

$$
X_l = \frac{1}{2} (\gamma^l + \eta^l) = \frac{1}{2} ((X_1 + Y_1 \sqrt{d})^l + (X_l - Y_l \sqrt{d})^l)
$$

= $\frac{1}{2} ((X_1 + \sqrt{X_1^2 - 1})^l + (X_1 - \sqrt{X_1^2 - 1})^l) := P_l(X_1).$

Now from [\(39\)](#page-10-3) finding a bound for l_1 as,

$$
l_1 < \frac{(2 \cdot 253) \log 3 + \log 2.5}{\log \gamma}.\tag{45}
$$

We know that $X_1 \ge \sqrt{d-1}$ and $\gamma > 2\sqrt{d-2}$. Assume that $d > 401$, which gives $X_1 > 20$ and $l_1 \le 150$. Now from [\(37\)](#page-9-2),

$$
P_{l_1}(X_1) := 2^{a_1} 3^{a_2} \tag{46}
$$

with $a_2 \in [0, 253], a_1 \in [0, a_2], l_1 \in [2, 150]$ and $X_1 > 20$. Note that $l_1 \geq 2$, because if we are taking $l_1 = 1$ we get $P_{l_1}(X_1) = X_1$. In this case there is nothing to solve.

For the case $l_1 > 1$ and $d > 401$, a quick computer search on [\(46\)](#page-11-0) yields nothing; so if $l_1 > 1$ then $1 < d \leq 401$. In this case also, we are not getting any solutions.

Since l_1 to be minimal, we must have $l_1 = 1$ for all d. Also $\gamma = X_1 + \sqrt{X_1^2 - 1}$. From [\(41\)](#page-10-4),

$$
|l\log\gamma - (n_1+1)\log 2 - n_2\log 3| < \frac{2}{3^{n_2}}.
$$

Rearranging and comparing with Lemma [3.5,](#page-4-2)

$$
m := n_2, \tau := \frac{\log 3}{\log \gamma}, \mu := \frac{254 \cdot \log 2}{\log \gamma}, A := \frac{2}{\log \gamma}, B := 3, k := n_2.
$$

We have an upper bound for b_2 , which is $M_4 := 1.179 \cdot 10^{19}$. Reduce this bound again and denote the reduced bound by $M_5(X_1)$ for each X_1 . Using Mathematica we get, max $M_5(X_1) = 52$. The X-coordinates of [\(7\)](#page-2-0) satisfies the recurrence relation,

$$
X_l = 2X_1 X_{l-1} - X_{l-2}
$$

and for each X_1 a bound for l_2 is obtained using [\(39\)](#page-10-3) denoting it by $l(X_1)$:

$$
l_2 < \frac{2 \cdot M_5(X_1) \log 3 + \log 2.5}{\log \gamma} := l(X_1).
$$

So, max $l(X_1) = 130$. Now finding the minimum of $\epsilon_1(X_1)$ of Lemma [3.5](#page-4-2) as $\min_{X_1} \epsilon_1(X_1) =$

0.0011. Now it remains to verify whether $\frac{X_{l_2}}{2h_1}$ $rac{\lambda_1}{3^{b_2}}$ is of the form 2^{b_1} . Checking this for each value of X_1 in the range

$$
l_2 \in [2, 130] \text{ and } b_2 \in [0, 52]
$$

using Mathematica, we find no solutions. This completes the proof of the Theorem [2.2.](#page-3-3)
