Abstract

A substring *u* of a string *T* is said to be a *repeat* if *u* occurs at least twice in *T*. An occurrence [*i..j*] of a repeat *u* in *T* is said to be a *net occurrence* if each of the substrings *aub* = *T*[*i* − 1*..j* + 1], $au = T[i - 1, j + 1]$, and $ub = T[i, j + 1]$ occurs exactly once in *T*. The occurrence $[i - 1, j + 1]$ of *aub* is said to be an *extended* net occurrence of *u*. Let *T* be an input string of length *n* over an alphabet of size σ , and let $\text{ENO}(T)$ denote the set of extended net occurrences of repeats in T. Guo et al. [SPIRE 2024] presented an online algorithm which can report $\text{ENO}(T[1..i])$ in $T[1..i]$ in $O(n\sigma^2)$ time, for each prefix *T*[1*..i*] of *T*. Very recently, Inenaga [arXiv 2024] gave a faster online algorithm that can report $\text{ENO}(T[1..i])$ in optimal $O(\text{HENO}(T[1..i]))$ time for each prefix $T[1..i]$ of *T*, where #*S* denotes the cardinality of a set *S*. Both of the aforementioned data structures can be maintained in $O(n \log \sigma)$ time and occupy $O(n)$ space, where the $O(n)$ -space requirement comes from the suffix tree data structure. In particular, Inenaga's recent algorithm is based on Weiner's right-to-left online suffix tree construction. In this paper, we show that one can modify Ukkonen's left-to-right online suffix tree construction algorithm in $O(n)$ space, so that $\text{ENO}(T[1..i])$ can be reported in optimal $O(\#ENO(T[1..i]))$ time for each prefix $T[1..i]$ of T . This is an improvement over Guo et al.'s method that is also based on Ukkonen's algorithm. Further, this leads us to the two following space-efficient alternatives:

- A *sliding-window* algorithm of $O(d)$ working space that can report $\text{ENO}(T[i-d+1..i])$ in optimal $\overline{}$ $O(\# \text{ENO}(T[i - d + 1..i]))$ time for each sliding window $T[i - d + 1..i]$ of size *d* in *T*.
- A *CDAWG*-based online algorithm of $O(e)$ working space that can report $ENO(T[1..i])$ in optimal \blacksquare $O(\# \text{ENO}(T[1..i]))$ time for each prefix $T[1..i]$ of *T*, where $e < 2n$ is the number of edges in the CDAWG for *T*.

All of our proposed data structures can be maintained in $O(n \log \sigma)$ time for the input online string *T*. We also discuss that the extended net occurrences of repeats in *T* can be fully characterized in terms of the *minimal unique substrings* (*MUSs*) in *T*.

1 Introduction

Finding *repeats* in a string is a fundamental task of string processing that has applications in various fields including bioinformatics, data compression, and natural language processing. This paper focuses on the notion of *net occurrences* of a repeat in a string, which has attracted recent attention. Let *u* be a repeat in a string *T* such that *u* occurs at least twice in *T*. An occurrence $[i..j]$ of a repeat u in T is said to be a net occurrence of u if extending the occurrence to the left or to the right results in a unique occurrence, i.e., each of $aub = T[i - 1..j + 1], au = T[i - 1..j], and ub = T[i..j + 1]$ occurs exactly once in *T*. Finding string net occurrences are motivated for Chinese language text processing [\[13,](#page-12-0) [14\]](#page-12-1). The occurrence $[i - 1..j + 1]$ of *aub* is said to be an *extended net occurrence* of a repeat *u* in *T*, and let ENO(*T*) denote the set of all extended net occurrences of repeats in *T*.

Guo et al. [\[5\]](#page-11-0) were the first who considered the problem of computing (extended) net occurrences of repeats in a string from view points of string combinatorics and algorithmics. Guo et al. [\[5\]](#page-11-0) showed a necessary and sufficient condition for a net occurrence of a repeat, which, since then, has played a core role in efficient computation of string net occurrences. For an input string *T* of length *n*, they gave an *offline* algorithm for computing ENO(*T*) in $O(n)$ time and space for integer alphabets of size polynomial in *n*, and in $O(n \log \sigma)$ time and $O(n)$ space for general ordered alphabets of size σ . Their offline method is based on the suffix array [\[15\]](#page-12-2) and the Burrows-Wheeler transform [\[4\]](#page-11-1). Ohlebusch et al. gave another offline algorithm that works fast in practice [\[18\]](#page-12-3).

Later, Guo et al. [\[6\]](#page-12-4) proposed an *online* algorithm for computing all string net occurrences of repeats. Their algorithm maintains a data structure of $O(n)$ space that reports $\text{ENO}(T[1..i])$ in $O(n\sigma^2)$ time for each prefix $T[1..i]$ of an online input string T of length n . Since their algorithm computes all the net occurrences upon a query, their algorithm requires at least $O(n^2\sigma^2)$ time to *maintain and update* the list of all (extended) net occurrences of repeats in an online string. Their algorithm is based on Ukkonen's left-to-right online suffix tree construction [\[22\]](#page-12-5), that is enhanced with the suffix-extension data structure of Breslauer and Italiano [\[3\]](#page-11-2).

Very recently, Inenaga [\[8\]](#page-12-6) proposed a faster algorithm that can maintain $\text{ENO}(T[1..i])$ for an online string $T[1..i]$ with growing $i = 1, ..., n$ in a total of $O(n \log \sigma)$ time and $O(n)$ space. Namely, this algorithm uses only amortized $O(\log \sigma)$ time to update $\text{ENO}(T[1..i])$ to $ENO(T[1..i + 1])$. The proposed algorithm is based on Weiner's right-to-left online suffix tree construction [\[23\]](#page-12-7) that is applied to the reversed input string, and can report all extended net occurrences of repeats in $T[1..i]$ in optimal $O(\#ENO(T[1..i]))$ for each $1 \le i \le n$, where $\#S$ denotes the cardinality of a set *S*.

In this paper, we first show that Ukkonen's left-to-right online suffix tree construction algorithm can also be modified so that it can maintain and update $ENO(T[1..i])$ in a total of $O(n \log \sigma)$ time with $O(n)$ space, and can report $\text{ENO}(T[1..i])$ in optimal $O(\text{HENO}(T[1..i]))$ time for each $i = 1, \ldots, n$. While this complexity of our Ukkonen-based method is the same as the previous Weiner-based method [\[8\]](#page-12-6), our method enjoys the following merits:

- (1) Our result shows that the arguably complicated suffix-extension data structure of Breslauer and Italiano is not necessary for online computation of string net occurrences with Ukkonen's algorithm.
- (2) The new method can be extended to the *sliding suffix trees* [\[11,](#page-12-8) [21,](#page-12-9) [12\]](#page-12-10) and the *compact directed acyclic word graphs* (*CDAWGs*) [\[2,](#page-11-3) [9\]](#page-12-11).

The first point is a simplification and improvement over Guo et al.'s method [\[6\]](#page-12-4) based on Ukkonen's construction. The second point leads us to the following space-efficient alternatives:

- A sliding-window algorithm of $O(d)$ working space that can be maintained in $O(n \log \sigma)$ time and can report $\text{ENO}(T[i - d + 1..i])$ in optimal $O(\text{HENO}(T[i - d + 1..i]))$ time for each sliding window $T[i - d + 1..i]$ of size *d* in *T*.
- \blacksquare A CDAWG-based online algorithm of $O(e)$ working space that can be maintained in $O(n \log \sigma)$ time and can report $\text{ENO}(T[1..i])$ in optimal $O(\text{HENO}(T[1..i]))$ time for each prefix *T*[1*..i*] of *T*, where e is the number of edges in the CDAWG for *T*.

We note that $e < 2n$ always holds [\[2\]](#page-11-3), and e can be as small as $O(\log n)$ for some highly repetitive strings [\[20,](#page-12-12) [19\]](#page-12-13). Finally, we also discuss that the extended net occurrences of repeats in a string *T* can be fully characterized with the *minimal unique substrings* (*MUSs*) [\[7\]](#page-12-14) in *T*.

2 Preliminaries

Strings.

Let Σ be an alphabet. An element of Σ is called a character. An element of Σ^* is called a string. The empty string ε is the string of length 0. If $T = pfs$ holds for strings T, p, f , and *s*, then *p, f*, and *s* are called a prefix of *T*, a substring of *T*, and a suffix of *T*, respectively. A prefix *p* (resp. a suffix *s*) of *T* is called a *proper* prefix (resp. a *proper* suffix) of *T* if $p \neq T$ (resp. $s \neq T$). For a string *T*, |*T*| denotes the length of *T*. For a string *T* and an integer *i* with $1 \leq i \leq |T|$, $T[i]$ denotes the *i*th character of *T*. For a string *T* and integers *i, j* with $1 \leq i \leq j \leq |T|$, *T*[*i..j*] denotes the substring of *T* starting at position *i* and ending at position *j*. For strings *T* and *w*, we say *w occurs* in *T* if $T[i..j] = w$ holds for some *i, j*. Also, if such *i, j* exist, we denote by $[i..j]$ the *occurrence* of $w = T[i..j]$ in *T*. Also, we denote by $\text{occ}_T(w)$ the set of occurrences of *w* in *T*, i.e., $\text{occ}_T(w) = \{[i..j] \mid T[i..j] = w\}$. For any set S , we denote by $\#S$ the cardinally of S . For convenience, we assume that the empty string ε occurs $|T| - 1$ times at the boundaries of consecutive characters in *T*, and denote these inner occurrences by $T[i+1..i] = \varepsilon$ for $1 \leq i \leq n$. We also assume that ε occurs before the first character and after the last character of *T*. Thus we have $\#\text{occ}_T(\varepsilon) = |T| + 1$. A string *w* is said to be *unique* in *T* if $\# occ_T(w) = 1$. Also, *w* is said to be *quasi-unique* in *T* if $1 \leq #occ_T(w) \leq 2$. Further, *w* is said to be *repeating* in *T* if $#occ_T(w) \geq 2$. We denote by $lrSuf(T)$ (resp. $lrPref(T)$) the longest repeating suffix (resp. prefix) of *T*. We denote by $sgSuf(T)$ (resp. $sgPref(T)$) the shortest quasi-unique suffix (resp. prefix) of *T*.

Maximal repeats and minimal unique substrings.

A repeating substring of a string *T* is also called a *repeat* in *T*. A repeat *u* in *T* is said to be *left-branching* in *T* if there are at least two distinct characters $a, a' \in \Sigma$ such that $\# occ_T(au) \geq 1$ and $\# occ_T(a'u) \geq 1$. Symmetrically, a repeat *u* is said to be *right-branching* in *T* if there are at least two distinct characters $b, b' \in \Sigma$ such that $\# occ_T(ub) \geq 1$ and $\# occ_T(ub') \geq 1$. A repeat *u* of *T* is said to be *left-maximal* in *T* if *u* is a left-branching repeat of *T* or *u* is a prefix of *T*, and *u* is said to be *right-maximal* in *T* if *u* is a right-branching repeat in *T* or *u* is a suffix of *T*. A repeat *u* of *T* is said to be *maximal* in *T* if *u* is both a left-maximal repeat and a right-maximal repeat in *T*. Let $LB(T)$, $RB(T)$, $LM(T)$, $RM(T)$, and $M(T)$ denote the sets of left-branching, right-branching, left-maximal, right-maximal, and maximal repeats in *T*, respectively. Note that $\mathsf{LB}(T) \subseteq \mathsf{LM}(T)$, $\mathsf{RB}(T) \subseteq \mathsf{RM}(T)$, and $M(T) = LM(T) \cap RM(T)$ hold. A unique substring $u = T[i..j]$ of a string T is said to be a *minimal unique substring* (*MUS*) of *T* if each of the substrings $T[i - 1, j]$ and $T[i, j - 1]$ is a repeat in *T*. By definition, no MUS can be completely contained in another MUS in the string, and thus, there are at most *n* MUSs in any string *T* of length *n*. Let $MUS(T)$ denote the set of occurrences of all MUSs in *T*.

In what follows, we fix a string T of length $n > 2$ arbitrarily.

(Extended) net occurrences.

For a repeating substring *P* of *T*, its occurrence [*i..j*] in *T* is said to be a *net occurrence* of *P* if $T[i..j] = P$, $T[i-1..j]$ is unique in *T*, and $T[i..j+1]$ is unique in *T*. Let $NO(T)$ be the set of net occurrences in *T*. We call $T[i - 1..j + 1]$ a net unique substring (NUS) if [*i..j*] ∈ NO(*T*). Let NUS(*T*) be the set of net unique substrings in *T*. Then, we call the occurrence [*i*−1*..j* + 1] of NUS *T*[*i*−1*..j* + 1] the *extended net occurrence* of the repeat *T*[*i..j*]. Let $ENO(T)$ be the set of extended net occurrences in T. Clearly, there is a one-to-one

correspondence between $NUS(T)$ and $ENO(T)$, i.e., $T[p,q] \in NUS(T)$ iff $[p,q] \in ENO(T)$. Note that $\#ENO(T) = \#NO(T)$ holds.

Data structures.

The *suffix tree* [\[23\]](#page-12-7) of a string *T* is a compacted trie that represents all suffixes of *T*. More formally, the suffix tree of T is a rooted tree such that (1) each edge is labeled by a non-empty substring of *T*, (2) the labels of the out-edges of the same node begin with distinct characters, and (3) every suffix of *T* is represented by a path from the root. If the path from the root to a node *v* spells out the substring *w* of *T*, then we say that the node *v represents w*. By representing each edge label *x* with a pair (i, j) of positions such that $x = T[i..j]$, the suffix tree can be stored in $O(n)$ space. For convenience, we identify each node with the string that the node represents. If *av* is a node of the suffix tree with $a \in \Sigma$ and $v \in \Sigma^*$, then the *suffix link* of the node *av* points to the node *v*.

There are two versions of suffix trees, *implicit suffix trees* [\[22\]](#page-12-5) (a.k.a. *Ukkonen trees*) and *explicit suffix trees* [\[23\]](#page-12-7) (a.k.a *Weiner trees*). In the implicit suffix tree of string *T*, each repeating suffix *s* of *T* that has a unique right-extension $c \in \Sigma$ (namely, $\# occ_T(sc) \geq 1$ and $\#occ_T(sa) = 0$ for any $a \in \Sigma \setminus \{c\}$ is represented on an edge. On the other hand, each such repeating suffix is represented by a non-branching internal node in the explicit suffix tree of *T*. Let STree′ (*T*) and STree(*T*) denote the implicit suffix tree and the explicit suffix tree of string *T*, respectively. The internal nodes of STree′ (*w*) represent the right-branching repeats of *T*, while the internal nodes of $\text{STree}(w)$ represent the right-maximal repeats of *T*. It is thus clear that $STree'(T\$ ^{\$}) = $STree(T\$ ^{\$}) with a unique end-marker $\$ that does not occur in *T*. Due to the nature of left-to-right online string processing, we will use the implicit suffix trees in our algorithms.

Figure 1 The implicit suffix tree $\text{STree}'(T)$, the explicit suffix tree $\text{STree}(T)$, the implicit CDAWG CDAWG'(T), and the explicit CDAWG CDAWG'(T) for string $T =$ abbbabbabbab. The broken arrows represent suffix links. The white and gray stars represent the loci of the longest repeating suffix bbabbab and shortest quasi-unique suffix abbab of *T*, respectively.

The *compact directed acyclic word graph* (*CDAWG*) [\[2\]](#page-11-3) of a string *T* is the smallest edgelabeled DAG that represents all substrings of *T*. There are two versions of CDAWGs as well, *implicit CDAWGs* [\[9\]](#page-12-11) and *explicit CDAWGs* [\[2\]](#page-11-3). The implicit CDAWG of string *T*, denoted $CDAWG'(T)$, is the edge-labeled DAG that is obtained by merging all isomorphic subtrees of the implicit suffix tree $\text{STree}'(T)$ which are connected by suffix links. On the other hand, the explicit CDAWG of T , denoted CDAWG (T) , is the edge-labeled DAG that is obtained by merging all isomorphic subtrees of the explicit suffix tree $STree(T)$ which are connected by suffix links. The internal nodes of $CDAWG'(T)$ have a one-to-one correspondence with the left-maximal and right-branching repeats in *T*, while the internal nodes of CDAWG(*T*) have a

Mieno and Inenaga 5

one-to-one correspondence with the maximal repeats in *T*. More precisely, the longest string represented by an internal node in CDAWG′ (*T*) is a left-maximal and right-branching repeat in *T*, and the longest string represented by an internal node in $CDAWG(T)$ is a maximal repeat in *T*. Thus, as in the case of suffix trees, $CDAWG'(T\$ ^{\$} $) = CDAWG(T\$ ^{\$} $)$ holds with a unique end-marker \$.

The length of a path in the implicit/explicit CDAWG is the total length of the labels of the edges in the path. An in-edge of a node *v* in the implicit/explicit CDAWG is said to be a *primary edge* if it belongs to the longest path from the source to *v*.

Due to the nature of left-to-right online string processing, we will use the implicit CDAWGs in our algorithm. Let $e'(T)$ and $e(T)$ denote the number of edges of CDAWG'(T) and $CDAWG(T)$, respectively. The following lemma guarantees that the worst-case space complexity of our implicit-CDAWG based algorithm is linear in the size of explicit CDAWGs:

 \blacktriangleright **Lemma 1.** For any string T , $e'(T) \leq e(T)$.

Proof. Let V' and V be the sets of nodes of CDAWG'(*T*) and CDAWG(*T*), respectively. We identify each node of V' and of V with the longest string that the node represents. Then, $V' = LM(T) \cap RB(T)$ and $V = LM(T) \cap RM(T) = M(T)$. Since $RB(T) \subseteq RM(T)$, we have that $V' \subseteq V$. Let $w \in LM(T) \cap RB(T)$, which implies that $w \in V'$ and $w \in V$. Let v' and v be the nodes that represent w in CDAWG'(*T*) and CDAWG(*T*), respectively. The out-degree $d(v')$ of node v' in CDAWG'(T), as well as the out-degree $d(v)$ of v in CDAWG(*T*), are equal to the number of right-extensions $c \in \Sigma$ such that $\# occ_T(wc) \geq 1$. Thus $e'(T) = \sum_{v' \in V'} d(v') \le \sum_{u \in V} d(u) = e(T)$.

3 Changes in net occurrences for online string

In this section, we show how the net unique substrings, equivalently the extended net occurrences in a string *T* can change when a character is appended. We will implicitly use the following fact throughout this section.

▶ **Fact 2.** For any strings T, w , and character c , $\# occ_T(w) \leq # occ_{Tc}(w)$ holds.

Thus, if *w* is repeating in *T*, then it must be repeating in *Tc*. Further, if *w* is unique in Tc and is not a suffix of *T c*, then *w* must be unique in *T*.

Next lemma characterizes net unique substrings to be deleted when a character *c* is appended to string *T*.

▶ **Lemma 3.** *Suppose that* $aub \in NUS(T) \setminus NUS(Tc)$ *be a net unique substring in T* where $a, b, c \in \Sigma$ and $u \in \Sigma^*$. Then, (i) $au = sgSuf(Tc)$ and $\# occ_{Tc}(au) = 2$ or (ii) $ub = lrSuf(Tc)$ $and \# occ_{Tc}(ub) = 2 \text{ hold.}$

Proof. Since $aub \in NUS(T)$, au is unique in *T*, ub is unique in *T*, and *u* is repeating in *T*. Also, since *aub* \notin NUS(*Tc*), *au* or *ub* becomes repeating in *Tc*. See also Figure [2.](#page-5-0) Note that *au* and *ub* cannot be repeating in Tc, because if we assume they become repeating in *T c* simultaneously, then both *au* and *ub* are suffixes of *T c* and this implies *au* = *ub*, which contradicts that *au* is unique in *T*.

If *au* is repeating in *Tc*, then *au* is a suffix of *Tc*. Since *au* is unique in *T*, $\# occ_{T_c}(au) = 2$ holds. Also, since *u* is repeating in *T*, $\# occ_{T_c}(u) \geq 3$ holds. These imply that $au = sgSuf(T_c)$.

If *ub* is repeating in *Tc*, then *ub* is a suffix of *Tc*. Since *ub* is unique in *T*, $\# occ_{T_c}(u b) = 2$ holds. Now let $a' = T||T| - |u||$ be the preceding character of the suffix *ub* of *Tc*. If we

Figure 2 Illustration for Lemma [3.](#page-4-0) The upper part depicts the case where *au* is repeating in *T c*. The lower part depicts the case where *ub* is repeating in T_c

Figure 3 Illustration for Lemma [4.](#page-5-1) Suffix *u* of *T c* is repeating in *T c* but longer suffix *a* ′*u* of *T c* is unique in T_c .

assume that $a'ub$ is repeating in Tc, then the other occurrence $a'ub$ matches the occurrence of *aub* since *ub* is unique in *T*. This implies that $a' = a$, which contradicts *au* is unique in *T*. Thus, $ub = lrSuf(Tc)$.

▶ **Lemma 4.** Suppose that $aub \in NUS(Tc) \setminus NUS(T)$ be a net unique substring in Tc such *that aub is not a suffix of Tc where* $a, b, c \in \Sigma$ *and* $u \in \Sigma^*$. *Then,* $u = \text{lr} \text{Suf}(Tc)$ *and* $\# occ_{Tc}(u) = 2 \text{ hold.}$

Proof. Since $aub \in NUS(Tc)$, *au* is unique in *Tc*, *ub* is unique in *Tc*, and *u* is repeating in *Tc.* Also, since $aub \notin NUS(T)$, *u* is unique in *T*. Namely, *u* occurs in *Tc* as a suffix and $\# occ_{Tc}(u) = 2$. See also Figure [3.](#page-5-2) Since *au* is unique in *Tc*, the preceding character *a*' of $u = T||Tc| - |u| + 1$... $|Tc||$ is not equal to *a*, and thus, $a'u$ is unique in Tc. Therefore, $u = lrSuf(Tc)$ holds.

▶ **Lemma 5.** *Suppose that auc* ∈ NUS(*T c*) \ NUS(*T*) *be a net unique substring in T c such that auc is a suffix of* $T c$ *where* $a, c \in \Sigma$ *and* $u \in \Sigma^*$ *. Then, either (i)* $u = lrSuf(T)$ *or (ii)* $u = c^{exp}$ *and* $\# occ_T(u) = 1$ *where* $exp = max\{e \mid c^e$ *is a suffix of* $T\}$ *.*

Proof. Since $auc \in NUS(Tc)$, *au* is unique in *Tc*, *uc* is unique in *Tc*, and *u* is repeating in T_c . There are two cases with respect to the number of occurrences of u in T . See also Figure [4.](#page-6-0)

If *u* is repeating in *T*, $u = \text{lr}Suf(T)$ since *au* is unique in *T*. If *u* is unique in *T*, then appending *c* causes *u* to be repeating in *T*. This implies that $u = u[2..|u|]c$, i.e., $u = c^{|u|}$. Also, since $uc = c^{|u|+1}$ is unique in Tc , $a \neq c$ holds. Thus $|u| = exp = max\{e \mid u$ c^e is a suffix of *T*}.

Figure 4 Illustration for Lemma [5.](#page-5-3) The upper part depicts the case where *u* is repeating in *T*. The lower part depicts the case where *u* is unique in *T*.

As for the differences between $NUS(T)$ and $NUS(cT)$, the three following lemmas also hold by symmetry:

▶ **Lemma 6.** *Suppose that* $aub \in NUS(T) \setminus NUS(cT)$ *be a net unique substring in T* where $a, b, c \in \Sigma$ and $u \in \Sigma^*$. Then, (i) $au = \text{sqPref}(c)$ and $\text{#}occ_{c}(\overline{a}u) = 2$ or (ii) $ub =$ l *rPref*(*cT*) *and* $\# occ_{cT}(ub) = 2$ *hold.*

▶ **Lemma 7.** *Suppose that* $aub \in NUS(cT) \setminus NUS(T)$ *be a net unique substring in cT such that aub is not a prefix of cT where* $a, b, c \in \Sigma$ *and* $u \in \Sigma^*$. *Then,* $u = \text{lrPref}(cT)$ *and* $\# occ_{cT}(u) = 2 \text{ hold.}$

▶ **Lemma 8.** *Suppose that* $auc \in NUS(cT) \setminus NUS(T)$ *be a net unique substring in cT such that auc is a prefix of cT where* $a, c \in \Sigma$ *and* $u \in \Sigma^*$. Then, either (i) $u = lrPref(T)$ *or (ii)* $u = c^{exp}$ and $\# occ_T(u) = 1$ where $exp = max\{e \mid c^e$ is a prefix of $T\}$.

4 Algorithms

In this section, we present our online/sliding algorithms for computing extended net occurrences of repeats for a given string.

4.1 Online algorithm based on implicit suffix trees

By Lemmas [3,](#page-4-0) [4](#page-5-1) and [5,](#page-5-3) we can compute $\mathsf{ENO}(T_c)$ from $\mathsf{ENO}(T)$ with Algorithm [1](#page-7-0) since $[p..q] \in \text{ENO}(T)$ iff $T[p..q] \in \text{NUS}(T)$. We encode each element $[i..j] \in \text{ENO}(T)$ by a pair (i,j) so that $\text{ENO}(T)$ can be stored in $O(\text{#ENO}(T))$ space. Note that $\text{#ENO}(Tc) - \text{#ENO}(T) \neq -2$ while $\#(\text{ENO}(T_c) \setminus \text{ENO}(T))$ can be 2. See lines 9–15 of Algorithm [1.](#page-7-0) The size of E decreases by 1 if we enter line 12, however, the size increases by 1 at line 14. Thus $-1 \leq #ENO(Tc) - #ENO(T) \leq 2.$

From Algorithm [1,](#page-7-0) we obtain the following theorem:

 \triangleright **Theorem 9.** *Given string T*, $E = \text{ENO}(T)$ *, and character c, we can compute* $\text{ENO}(T_c)$ *in* $O(t(n))$ *time using* $O(s(n))$ *space if each of the following operations can be executed in* $t(n)$ *time within s*(*n*) *space:*

- **1.** *Determine if* $\# occ_{Tc}(sqSuf(Tc)) = 2$ *.*
- **2.** Find the non-suffix occurrence of $sgSuf(Tc)$ in Tc when $\# occ_T(c)$ $sgSuf(Tc)) = 2$.
- **3.** *Determine* if $\# occ_{Tc}(lrSuf(Tc)) = 2$ *.*

- **9.** *Delete an element* (i, j) *from* E *if* $(i, j) \in E$ *for given pair* (i, j) *.*

Proof. Look at Algorithm [1.](#page-7-0) Line [2](#page-7-0) uses operation 1, Line [3](#page-7-0) uses operation 2, Lines [4](#page-7-0) and [11](#page-7-0) use operation 7, Lines [5](#page-7-0) and [12](#page-7-0) use operation 9, Line [8](#page-7-0) uses operation 3, Line [9](#page-7-0) uses operation 4, Lines [14, 18,](#page-7-0) and [20](#page-7-0) use operation 8, Line [17](#page-7-0) uses operation 5, and Line [19](#page-7-0) uses operation 6. Thus, Algorithm [1](#page-7-0) consists of the above nine operations and basic arithmetic \bullet operations. \bullet

Note that the correctness of Theorem [9](#page-6-1) does not depend on the data structure used. The next lemma holds if we utilize the *implicit suffix tree* by Ukkonen [\[22\]](#page-12-5).

▶ **Lemma 10.** *Based on Ukkonen's left-to-right online suffix tree construction [\[22\]](#page-12-5), we can design a data structure* \mathcal{D}_T *of size* $O(|T|)$ *that supports all nine operations of Theorem [9](#page-6-1) in constant time. The data structure* \mathcal{D}_T *can be updated to* \mathcal{D}_{T_c} *in amortized* $O(\log \sigma)$ *time where c is a character.*

Proof. We employ an implicit suffix tree [\[22\]](#page-12-5) of online string *T* enhanced with the *active point*, which represents $lrSuf(T)$, and the *secondary active point*, which represents $sqSuf(T)$

Mieno and Inenaga 9

as in [\[16\]](#page-12-15). According to [\[16\]](#page-12-15), such an enhanced implicit suffix tree can support operations 1–6 in *O*(1) time. For the readers of this paper, we briefly explain how to perform those operations efficiently below:

- \Box Operation 5 is obvious since we maintain the active point for every step.
- Operation 3 can be easily done in constant time by checking whether the active point \mathbf{r} locates on an edge towards a leaf or not.
- Operation 1 can be done in constant time by using the (secondary) active points (due to Lemma 1 of $[16]$).
- \blacksquare Operations 2 and 4 can be done by looking at the leaves under the (secondary) active points. For instance, look at the implicit suffix tree STree′ (*T*) depicted in Figure [1.](#page-3-0) The secondary active point (the gray star), which represents the shortest quasi-unique suffix $s =$ **abbab**, is on an edge towards a leaf. Further, the leaf under the secondary active point represents the suffix abbabbab of *T* starting at position 5. Thus, *s* occurs at position 5, which is the non-suffix occurrence of *s*. Similarly, the non-suffix occurrence of the longest repeating suffix bbabbab is position 3 since the leaf under the active point (the white star) represents the suffix of *T* starting at position 3.

Value *exp* defined in operation 6 can be easily maintained independent of the suffix tree. As for operations 7–9, we implement set $E = ENO(T)$ as a set of occurrences where each element $(i, j) \in E$ is connected to the corresponding locus of the suffix tree. Since $T[i..j]$ is unique in *T*, the locus of $T[i..j]$ is either the leaf corresponding to unique suffix $T[i..|T|]$ or on the edge towards the leaf. Thus we can perform operations 7–9 in constant time via the leaves of the suffix tree, for given (*i, j*), which represents some unique substring of *T*.

Finally, the data structure can be maintained in amortized $O(\log \sigma)$ time: Basically the amortized analysis is due to [\[22\]](#page-12-5). The secondary active point, which was originally proposed in [\[16\]](#page-12-15), can also be maintained in a similar manner to the active point, and thus the amortized analysis for the secondary active point is almost the same as that for the active point in $[22]$ (see $[16]$ for the complete proof).

By wrapping up the above discussions, we obtain the following theorem:

 \triangleright **Theorem 11.** We can compute the set of extended net occurrences of string T of length n *given in an online manner in a total of* $O(n \log \sigma)$ *time using* $O(n)$ *space.*

4.2 Sliding-window algorithm based on implicit suffix trees

By applying symmetric arguments of Theorem [9,](#page-6-1) we can design a sliding-window algorithm.

 \blacktriangleright **Lemma 12.** *There exists a data structure* \mathcal{D}_T *of size* $O(|T|)$ *that supports all nine operations of Theorem [9](#page-6-1) in addition to their symmetric operations listed below in constant time.*

- **1.** *Determine if* $\# occ_T(sqPref(T)) = 2$ *.*
- **2.** Find the non-prefix occurrence of $sqPref(T)$ in *T* when $\# occ_T(sqPref(T)) = 2$.
- **3.** *Determine* if $\# occ_T(lrPref(T)) = 2$ *.*
- **4.** Find the non-prefix occurrence of $lrPref(T)$ in T when $\# occ_T(lrPref(T)) = 2$.
- **5.** *Compute the lengths of* $lrPref(T[2..n])$ *and* $lrPref(T)$ *.*
- **6.** *Compute* $exp' = \max\{e \mid c^e \text{ is a prefix of } T[2..n]\}$ and determine if $\# occ_{T[2..n]}(c^{exp'}) = 1$ *where* $c = T[1]$ *.*

The data structure D_T *can be updated to either* $D_{T[2..|T|]}$ *or* D_{Tc} *in amortized* $O(\log \sigma)$ *time where c is a character.*

Proof. The sliding suffix tree data structure of [\[16\]](#page-12-15) supports all the operations in amortized $O(\log \sigma)$ time using $O(d)$ space.

In case we perform the deletion of the leftmost character and the addition of the rightmost character simultaneously, then our algorithm works for a sliding-window of fixed size *d*. On the other hand, our scheme is also applicable to a sliding-window of variable size. Thus we have the following:

▶ **Theorem 13.** *We can maintain the set of extended net occurrences for a sliding window over string T of length n in a total of* $O(n \log \sigma)$ *time using* $O(d)$ *working space where d is the maximum size of the window.*

4.3 Online algorithm based on implicit CDAWGs

The next lemma is an adaptation of Lemma [10](#page-7-1) which uses implicit CDAWGs in place of implicit suffix trees:

▶ **Lemma 14.** *Based on the left-to-right online CDAWG construction [\[9\]](#page-12-11), we can design a data structure* C_T *of size* $O(e(T))$ *that supports all nine operations of Theorem [9](#page-6-1) in constant time. The data structure* C_T *can be updated to* C_{T_c} *in amortized* $O(\log \sigma)$ *time where c is a character.*

Proof. Since the online implicit CDAWG construction algorithm [\[9\]](#page-12-11) is based on Ukkonen's implicit suffix tree construction, it also maintains the active point that indicates the locus corresponding to $lrSuf(T)$. While the locus can correspond to multiple substrings of *T* (as the CDAWG is a DAG), we can retrieve $|lrSuf(T)|$ in $O(1)$ time by storing, in each node v of CDAWG' (T) , the length of the maximal repeat corresponding to *v*. This is because the path that spells out $lrSuf(T)$ from the source consists only of the primary edges (see [\[9\]](#page-12-11) for more details). Since edge label *x* is represented by an integer pair (p, q) such that $x = T[p..q]$, we can obtain the non-suffix occurrence (i', j') of $lrSuf(T)$ in $O(1)$ time (Line [9](#page-7-0) in Algorithm [1\)](#page-7-0).

The secondary active point that indicates the locus for $sgSuf(T)$ can also be maintained on the implicit $CDAWG'(T)$ by adapting the algorithm from [\[16\]](#page-12-15). Let *y* be the suffix of *T* that is one-character shorter than $sgSuf(T)$. By definition, *y* is the longest suffix of *T* such that $\# occ_T(y) \geq 3$. Given the locus *P* for *y* on **CDAWG'**(*T*), one can check in *O*(1) time whether the substrings corresponding to P occur at least 3 times, by checking the number of paths from *P* to the sink and checking if the active point is in the subgraph under *P*. Also, by definition, *y* is the longest string represented by the locus *P*. This tells us the length of $sgSuf(T)$ as well. Thus, we can also maintain the secondary active point in a similar manner to the active point on the implicit CDAWG in $O(\log \sigma)$ amortized time per character, and we can obtain the non-suffix occurrence (i, j) of $sgSuf(T)$ in $O(1)$ time (Line [3](#page-7-0) in Algorithm [1\)](#page-7-0). The $O(\mathsf{e}(T))$ -space requirement follows from Lemma [1.](#page-4-1)

 \triangleright **Theorem 15.** We can compute the set of extended net occurrences of string T of length n *given in an online manner in a total of* $O(n \log \sigma)$ *time using* $O(e(T))$ *working space.*

Proof. The correctness and the time complexity follows from the above discussions.

It is shown in [\[9\]](#page-12-11) that the function $e'(T[1..i])$ is monotonically non-decreasing for any online string $T[1..i]$ with increasing $i = 1, ..., n$ $i = 1, ..., n$ $i = 1, ..., n$. Together with Lemma 1, we have $e'(T[1..i]) \le$ $e'(T) \leq e(T)$ for any $1 \leq i \leq n$, which leads to an $O(e(T))$ -space bound.

5 Relating extended net occurrences and MUSs

In this section, we give a full characterization of the extended net occurrences of repeats in *T* in terms of minimal unique substrings (MUSs) in *T*. See also Figure [5](#page-10-0) for illustration.

Figure 5 Illustration for Lemma [16](#page-9-0) and Lemma [17.](#page-10-1)

▶ **Lemma 16.** *Let* [*i* − 1*..h*]*,* [*k..j* + 1] ∈ MUS(*T*) *be the intervals that represent consecutive MUSs in T*, namely, there is no element [s..t] *in* $MUS(T)$ *such that* $i \leq s \leq k$ *and* $h \leq t \leq j$. *Then,* $[i..j]$ *is a net occurrence for repeat* $u = T[i..j]$ *.*

Proof. Observe that any unique substring of *T* must contain a MUS in *T*. Since $T[i..j]$ does not contain a MUS, $u = T[i..j]$ is a repeat in *T*. Let $a = T[i-1]$ and $b = T[j+1]$. Then, $\# occ_T(\text{aub }) = \# occ_T(\text{ au }) = \# occ_T(\text{ ub }) = 1$ since any of $\text{aub } = T[i-1..j-1], \text{ au } = T[i-1..j],$ and $ub = T[i..j + 1]$ contains a MUS.

A consequence of Lemma [16](#page-9-0) is that a net occurrence [*i..j*] cannot be contained in another net occurrence $[i'..j']$. This is because a MUS cannot be contained in another MUS. Another consequence is that two consecutive extended net occurrences in ENO(*T*) are overlapping.

Below we show the reversed version of Lemma [16:](#page-9-0)

▶ **Lemma 17.** *Let* $L = \text{ENO}(T) \cup \{ [1..p] \mid p = |lrPref(T)| + 1 \} \cup \{ [q..n] \mid q = n - |lrSuf(T)| \}$. *Let* $[h..j]$ *,* $[i..k] \in L$ *be consecutive elements in* L*, namely, there is no element* [*s..t*] *in* L *such that* $h < s < i$ *and* $j < t < k$ *. Then,* $[i..j] \in MUS(T)$ *.*

Proof. By the definition of the extended net occurrences, there is a MUS [*x..j*] with $x \geq h+1$ that ends at *j* since $T[h+1..j]$ is unique and $T[h+1..j-1]$ is repeating in *T*. Similarly, there is a MUS $[i..y]$ with $y \leq k-1$ that starts at *i*. Here, for the sake of contradiction, we assume $i \neq x$. If $i < x$, there are at least two MUSs within range $[i, j] \subset [h, k]$. If $i > x$, there are at least two MUSs within range $[x, y] \subset [h, k]$. In both cases, there exists some net occurrence within range $[h, k]$ by Lemma [16,](#page-9-0) which contradicts that $[h..j]$ and $[i..k]$ are consecutive elements in L. Thus $i = x$ holds. Similarly, we can prove $j = y$, hence $[i..j] \in MUS(T)$.

Consider the case where $h = 1$ and $j = p$, namely $T[1..p]$ is the *shortest unique prefix* $(suPref)$ of *T*, and *T*[*i..k*] is the leftmost extended net occurrence in *T*. Again by the definition of the extended net occurrences, there is a MUS that begins at position *i*. Let $T[1..p] = ub$ where $u \in \Sigma^*$ and $b \in \Sigma$. Then, $u = l r P r e f(T)$. Since *ub* is unique and since $u = l r P r e f(T)$, there must exist a MUS that ends at position p (see Figure [5.](#page-10-0)) Using a similar argument as above, it can be proven that these two MUSs are the same. Thus $[i..p] \in MUS(T)$. The case where $i = q$ and $k = n$ is symmetric.

Consequently, the next theorem follows from Lemma [16](#page-9-0) and Lemma [17.](#page-10-1)

- \blacktriangleright **Theorem 18.** For any string T,
- (1) #ENO(*T*) = #MUS(*T*) 1*.*
- (2) $\text{ENO}(T)$ *can be obtained from the sorted* $\text{MUS}(T)$ *in optimal* $O(\#\text{ENO}(T))$ *time.*
- (3) MUS(*T*) can be obtained from the sorted $\text{ENO}(T)$, $|l r \text{Pref}(T)|$, and $|l r \text{Suf}(T)|$ in optimal $O(\# \text{ENO}(T))$ *time.*

We also have the following corollary for space-efficient computation of MUSs:

▶ **Corollary 19.** *We can maintain the set of all MUSs of a string T of length n given in an online manner in a total of* $O(n \log \sigma)$ *time using* $O(\epsilon(T))$ *working space, where* $\epsilon(T)$ *denotes the size of* CDAWG(*T*)*.*

Proof. By combining Theorem [15](#page-9-1) and Lemmas [16](#page-9-0) and [17,](#page-10-1) we obtain the corollary except for computation of $|l r Pref(T)|$. This can easily be maintained in the implicit CDAWG as follows. Let z be the node of $CDAWG'(T)$ from which the primary edge to the sink stems out. We identify *z* with the maximal repeat that the node represents. If the active point does not exist on this primary edge, then $|z| = |lrPref(T)|$. If the active point lies on this primary edge leading to the sink, then $|z| + k = |l r P r f(T)|$, where k is the offset of the active point on the primary edge from the node z .

For any string *T*, $\#MUS(T) \leq e(T)$ holds [\[10\]](#page-12-16). Together with Theorem [18,](#page-10-2) we obtain:

 \blacktriangleright **Corollary 20.** For any string T , $\#$ **ENO** $(T) < e(T)$ *holds.*

6 Conclusions and open questions

In this paper we presented how Ukkonen's left-to-right online suffix tree construction can be used for online computation of string net frequency. Our main contributions are space-efficient algorithms for computing string net occurrences, one works in $O(d)$ space in the sliding model for window-length *d*, and the other works in $O(\mathsf{e}(T))$ space where $\mathsf{e}(T)$ denotes the size of the CDAWG of the input string *T*. Both of our methods run in $O(n \log \sigma)$ time and can report all (extended) net occurrences of repeats in the current string in output-optimal time. We also showed that computing the sorted list of extended net occurrences of repeats in a string *T* is equivalent to computing the sorted list of minimal unique substrings (MUSs) in *T*.

An intriguing open question is whether one can efficiently compute the extended net occurrences of repeats within $O(r)$ space, where r denotes the number of equal-character runs in the BWT of the input string. It is known that $r \le e$ holds for any string [\[1\]](#page-11-4). The *R-enum* algorithm of Nishimoto and Tabei [\[17\]](#page-12-17) is able to compute the set of MUSs in $O(n \log \log_n(n/r))$ time with $O(r)$ space, where ω denotes the machine word size of the word RAM model. However, it is unclear whether their algorithm can output a list of MUSs arranged in the sorted order of the beginning positions within $O(r)$ space.
