ABSTRACT

The paper considers the controller synthesis problem for general MIMO systems with unknown dynamics, aiming to fulfill the temporal reach-avoid-stay task, where the unsafe regions are time-dependent, and the target must be reached within a specified time frame. The primary aim of the paper is to construct the spatiotemporal tube (STT) using a sampling-based approach and thereby devise a closed-form approximation-free control strategy to ensure that system trajectory reaches the target set while avoiding time-dependent unsafe sets. The proposed scheme utilizes a novel method involving STTs to provide controllers that guarantee both system safety and reachability. In our sampling-based framework, we translate the requirements of STTs into a Robust optimization program (ROP). To address the infeasibility of ROP caused by infinite constraints, we utilize the sampling-based Scenario optimization program (SOP). Subsequently, we solve the SOP to generate the tube and closed-form controller for an unknown system, ensuring the temporal reach-avoid-stay specification. Finally, the effectiveness of the proposed approach is demonstrated through three case studies: an omnidirectional robot, a SCARA manipulator, and a magnetic levitation system.

1 Introduction

Autonomous systems have been a focal point in control theory, owing to their broad range of applications, including safety-critical situations such as self-driving cars and unmanned aerial vehicles. A principal challenge in deploying these systems is reaching specific targets while avoiding unsafe regions and respecting state constraints. The study of these reach-avoid-stay (RAS) specifications [1] becomes even more crucial as they often form the foundation for more complex specifications [2, 3]. This underlines the importance of developing and implementing safe and reliable control strategies.

The adoption of formal languages [4] to define tasks has led to the increasing popularity of symbolic control. This method abstracts the continuous state space into a finite symbolic model, simplifying the design of controllers with formal guarantees [4]. Enhancements such as the fixed-point algorithm for RAS controller synthesis [5], the integration of barrier certificates [6] and incrementally building a directed tree to approximate the product automaton's state space [7] have improved upon the traditional abstraction-based method. However, as the system becomes more

[†]Authors contributed equally.

complex or the granularity of the abstraction increases, the symbolic model expands exponentially, leading to greater computational complexity.

Alternatively, control barrier functions (CBFs) [8,9] offer a discretization-free approach to controller synthesis and have been extensively used for safety-critical systems [10, 11], particularly to meet obstacle avoidance [12], a class of signal temporal logic (STL) and linear temporal logic (LTL) specifications (excluding avoid specification) [9, 13], and RAS specifications [14]. While CBFs mitigate some of the scalability issues associated with symbolic control, they still rely on an optimization step, making them computationally demanding for high-dimensional systems. Additionally, CBFs require precise knowledge of system dynamics, which is a serious constraint for real-world systems.

Some other methods for achieving RAS objectives under disturbances include Hamilton-Jacobi (HJ) reachability [15], which ensures safety but is computationally infeasible for high-dimensional systems [16, 17] and requires precise system dynamics [18]. Gaussian processes (GP) [19] offer robustness by learning unknown dynamics but become computationally intensive as datasets grow [20]. Neural networks (NN) [21] can approximate complex dynamics but often lack formal safety guarantees [22].

Funnel-based control [23, 24] addresses these challenges by providing approximation-free closed-form control law that constrains tracking error within exponentially decaying funnel-shaped boundaries. This allows for rapid response to disturbances and changes in system dynamics without the overhead of real-time optimization. This approach has been used in tracking control problems in unknown nonlinear systems [24, 25] and multi-agent systems with intricate tasks [26]. Despite its success in meeting reachability specifications [3, 27], handling nonconvex requirements like avoiding unsafe areas remains significantly challenging [28, 29].

Some studies [30] combine path-planning algorithms with funnel-based tracking control to achieve RAS. However, separating the trajectory planning from funnel formulation can compromise avoid-constraints under disturbances. To address this [31, 32] enlarge the obstacles and construct paths in an extended free space. But, it reduces the available navigable area, potentially blocking paths that exist within the original free space. This added conservatism limits the controller's effectiveness in tight environments. Additionally, these works are restricted to static star-shaped and spherical obstacles, limiting their applicability to more general or dynamic obstacle configurations.

To solve this, the idea is to eliminate the trajectory generation step and directly design time-varying guidance functions in the state space, which ensures that the target set is reached within the prescribed time while avoiding time-dependent unsafe sets and adhering to state constraints. However, the main challenge lies in devising these time-varying guidance functions through the free state space. The spatiotemporal tube (STT) approach in [33], uses the circumvent function [34] to define smooth time-varying tube functions. The tubes adapt around the unsafe regions, providing a safe channel for the trajectory to enforce RAS and prescribed-time RAS tasks. However, it assumes unsafe sets are unions of convex sets and handle only control-affine dynamics. Moreover, the abrupt STT adjustments, due to the circumvent function, significantly increase the control effort.

In this paper, we propose a sampling-based technique, inspired from [35–37], to design STTs to address temporal-reach avoid stay specifications (T-RAS), i.e., given an initial set, the system trajectory should reach a target set within desired time interval while avoiding any time-varying unsafe sets. Given a T-RAS specification, we first frame the conditions of STTs as a robust optimization problem (ROP). We proceed by sampling points in time and the unsafe set to establish a scenario optimization program (SOP) associated with the ROP. By solving the SOP, we construct the STTs that adhere to the T-RAS specification with a formal correctness guarantee. Subsequently, we develop a closed-form approximation-free control law that ensures the output of a general higher-order unknown MIMO system remains within these tubes, thereby achieving T-RAS objectives. The efficacy of the proposed approach is demonstrated through the various case studies.

2 Preliminaries and Problem Formulation

2.1 Notation

The symbols \mathbb{N} , \mathbb{R} , \mathbb{R}^+ , and \mathbb{R}^+_0 denote the set of natural, real, positive real, and nonnegative real numbers, respectively. A vector space of real matrices with n rows and m columns is denoted by $\mathbb{R}^{n \times m}$. A column vector with n rows is represented by \mathbb{R}^n . The Euclidean norm is represented using $\|\cdot\|$. For $a, b \in \mathbb{N}$ with $a \leq b$, the closed interval in \mathbb{N} is denoted as [a; b]. A vector $x \in \mathbb{R}^n$ with entries x_1, \ldots, x_n is represented as $[x_1, \ldots, x_n]^\top$, where $x_i \in \mathbb{R}$ denotes the *i*-th element of vector $x \in \mathbb{R}^n$ and $i \in [1; n]$. A diagonal matrix in $\mathbb{R}^{n \times n}$ with diagonal entries d_1, \ldots, d_n is denoted by $\operatorname{diag}(d_1, \ldots, d_n)$. Given a matrix $M \in \mathbb{R}^{n \times m}$, M^\top represents transpose of matrix M. The power set of a set \mathbf{A} is defined as $\mathcal{P}(\mathbf{A})$. Given $N \in \mathbb{N}$ sets \mathbf{A}_i , $i \in [1; N]$, we denote the Cartesian product of the sets by $\mathbf{A} = \prod_{i \in [1;N]} \mathbf{A}_i := \{(x_1, \ldots, x_N) | x_i \in \mathbf{A}_i, i \in [1; N]\}$. The projection of a set $\mathbf{A} \subset \mathbb{R}^n$ onto the *i*-th dimension, where $i \in [1; n]$, is represented by an interval $[\mathbf{A}_{i,L}, \mathbf{A}_{i,U}] \subset \mathbb{R}$, where: $\mathbf{A}_{i,L} := \min\{x_i \in \mathbb{R} \mid [x_1, \dots, x_n] \in \mathbf{A}\}$, $\mathbf{A}_{i,U} := \max\{x_i \in \mathbb{R} \mid [x_1, \dots, x_n] \in \mathbf{A}\}$.

2.2 System Definition

Consider a class of control-affine MIMO nonlinear pure-feedback systems characterized by the following dynamics:

$$\dot{x}_{i}(t) = f_{i}(\overline{x}_{i}(t)) + g_{i}(\overline{x}_{i}(t))x_{i+1}(t) + w_{i}(t), i \in [1; N-1],
\dot{x}_{N}(t) = f_{N}(\overline{x}_{N}(t)) + g_{N}(\overline{x}_{N}(t))u(t) + w_{N}(t),
y(t) = x_{1}(t),$$
(1)

where for $t \in \mathbb{R}_0^+$ and $i \in [1; N]$,

- $x_i(t) = [x_{i,1}(t), \dots, x_{i,n}(t)]^\top \in \mathbf{X}_i \subset \mathbb{R}^n$ is the state vector,
- $\overline{x}_i(t) := [x_1^\top(t), x_2^\top(t), ..., x_i^\top(t)]^\top \in \overline{\mathbf{X}}_i = \prod_{j=1}^i \mathbf{X}_j \subset \mathbb{R}^{ni},$
- $u(t) \in \mathbb{R}^n$ is control input vector,
- $w_i(t) \in \mathbf{W} \subset \mathbb{R}^n$ is unknown bounded external disturbance, and
- $y(t) = [x_{1,1}(t), \dots, x_{1,n}(t)] \in \mathbf{Y} = \mathbf{X}_1$ denotes the output vector.

The functions $f_i: \overline{\mathbf{X}}_i \to \mathbb{R}^n$, $g_i: \overline{\mathbf{X}}_i \to \mathbb{R}^{n \times n}, i \in [1; N]$, follows the Assumptions 1 and 2.

Assumption 1 For all $i \in [1; N]$, functions f_i and g_i are unknown and locally Lipschitz.

Assumption 2 ([23,38]) The matrix $g_{i,s}(\overline{x}_i) := \frac{g_i(\overline{x}_i) + g_i(\overline{x}_i)^\top}{2}$ is uniformly sign definite with known signs for all $\overline{x}_i \in \overline{X}_i$. Without loss of generality, we assume $g_{i,s}(\overline{x}_i)$ is positive definite, i.e., there exists a constant $\underline{g}_i \in \mathbb{R}^+, \forall i \in [1; N]$ such that

$$0 < g_i \leq \lambda_{\min}(g_{i,s}(\overline{x}_i)), \forall \ \overline{x}_i \in \overline{\mathbf{X}}_i,$$

where $\lambda_{\min}(\cdot)$ represents the smallest eigenvalue of the matrix.

This assumption ensures that in (1) global controllability is guaranteed, i.e., $g_{i,s}(\overline{x}_i) \neq 0$, for all $\overline{x}_i \in \overline{\mathbf{X}}_i$.

Remark 2.1 While this paper considers a control-affine structure for the system in (1), the results can be extended to nonaffine systems. By leveraging techniques from the literature, such as affine transformations [39, 40] through coordinate changes or Taylor series expansions, we can include the additional terms that represent the discrepancy between the actual nonaffine dynamics and the affine approximation as an unknown disturbance within the model. This extension would enable a broader application of the proposed approach beyond control-affine dynamics.

2.3 **Problem Formulation**

Let the output of (1), *i.e.* y(t), be subject to a *temporal reach-avoid-stay specifications* defined next.

Definition 2.2 (Temporal reach-avoid-stay (T-RAS) task) Given an output-space $\mathbf{Y} = \mathbf{X}_1$, prescribed time $t_c \in \mathbb{R}^+$, a time-varying unsafe set $\mathbf{U} : \mathbb{R}_0^+ \to \mathcal{P}(\mathbf{Y})$, an initial set $\mathbf{S} \subset \mathbf{Y} \setminus \mathbf{U}(0)$, and a target set $\mathbf{T} \subset \mathbf{Y} \setminus \mathbf{U}(t_c)$, we say that the output of the system satisfies temporal reach-avoid-stay specifications if $y(0) \in \mathbf{S}$, $y(t_c) \in \mathbf{T}$ and for all $s \in [0, t_c], y(s) \in \mathbf{Y} \setminus \mathbf{U}(s)$.

Remark 2.3 $\mathbf{U}(t) = \bigcup_{j=1}^{p} \mathcal{U}^{(j)}(t)$, where $\mathcal{U}^{(j)}(t)$ represents time-dependent connected unsafe set. Hence, $\mathbf{U}(t)$ can be disconnected, representing multiple time-varying obstacles. Also, if \mathbf{Y} has an arbitrary shape, we redefine the output space as $\hat{\mathbf{Y}} = \prod_{i=1}^{n} [\mathbf{Y}_{i,L}, \mathbf{Y}_{i,U}]$ and expand the unsafe set to $\hat{\mathbf{U}}(t) = \mathbf{U}(t) \cup (\hat{\mathbf{Y}} \setminus \mathbf{Y})$.

Problem 2.4 Given the system in (1), we aim to design an approximation-free, closed-form control law u(t) ensuring the output y(t) adheres to the T-RAS specification defined in Definition 2.2.

To solve the aforementioned problem, we leverage the STTs defined next.

Definition 2.5 (Spatiotemporal Tubes for T-RAS task) Given a T-RAS task in Definition 2.2, time-varying intervals $[\gamma_{i,L}(t), \gamma_{i,U}(t)]$, where $\gamma_{i,L} : \mathbb{R}_0^+ \to \mathbb{R}$ and $\gamma_{i,U} : \mathbb{R}_0^+ \to \mathbb{R}$ are continuously differentiable functions with $\gamma_{i,L}(t) < \gamma_{i,U}(t)$, are called STTs for T-RAS, if for all $i \in [1; n]$, the following holds:

$$\prod_{i=1}^{n} [\gamma_{i,L}(t), \gamma_{i,U}(t)] \subseteq \mathbf{Y}, \forall t \in [0, t_c],$$
(2a)

$$\prod_{i=1}^{n} [\gamma_{i,L}(0), \gamma_{i,U}(0)] \subseteq \mathbf{S},\tag{2b}$$

$$\prod_{i=1}^{n} [\gamma_{i,L}(t_c), \gamma_{i,U}(t_c)] \subseteq \mathbf{T},$$
(2c)

$$\prod_{i=1}^{n} [\gamma_{i,L}(t), \gamma_{i,U}(t)] \cap \mathbf{U}(t) = \emptyset, \forall t \in [0, t_c].$$
(2d)

Remark 2.6 If one designs a control law that constrains the output trajectory within the STTs defined in Definition 2.5, *i.e.*,

$$\gamma_{i,L}(t) < y_i(t) < \gamma_{i,U}(t), \forall i \in [1;n], \implies \gamma_L(t) < x_1(t) < \gamma_U(t), \tag{3}$$

then one can ensure the satisfaction of T-RAS specification.

The STTs approach [33] increases the conservatism of the specifications by restricting the unsafe set to only a union of convex sets and requiring that the projection of the unsafe set does not overlap with the initial and target set in at least one dimension. Additionally, the circumvent function—a time-varying function used to capture the unsafe set—introduces sharp changes in the tube shape (as shown in Figure 1 of [33]), which increases control effort. To address these limitations and extend the concept of STTs of Definition 2.5 to more general T-RAS specifications mentioned in Definition 2.2, we propose a sampling-based approach in this paper.

3 Sampling-based Spatiotemporal Tubes Construction

In this section, the main goal is to construct the STTs that start from the initial set and reach the target set, avoiding the obstacles denoted by the unsafe sets.

In our sampling-based setting, we fix the structure of the curves that form the STTs for the *i*-th dimension as,

$$\gamma_{i,l}(c_{i,l},t) = \sum_{k=1}^{z_{i,l}} c_{i,l}^k p_{i,l}^k(t), \ l \in L, U, \ i \in [1;n],$$

where L and U denote the lower and upper constraints, respectively. $p_{i,l}(t)$ are user-defined nonlinear continuously differentiable basis functions and $c_{i,l} = [c_{i,l}^1; c_{i,l}^2; ...; c_{i,l}^{z_{i,l}}] \in \mathbb{R}^{z_{i,l}}$ denote the unknown coefficients.

To satisfy the conditions in Definition 2.5, we formulate the following Robust optimization program (ROP):

$$\begin{array}{l} \min_{[d_1,d_2,\ldots,d_n,\eta]} & \eta \\ \text{s.t.} \\ \forall i = [1;n], \gamma_{i,l}(c_{i,l},0) = \hat{\mathbf{S}}_{i,l}, \ \gamma_{i,l}(c_{i,l},t_c) = \hat{\mathbf{T}}_{i,l}; \end{array}$$
(4a)

$$\mathbf{Y}_{i,L} - \gamma_{i,L}(c_{i,L},t) \le \eta_i, \gamma_{i,U}(c_{i,U},t) - \mathbf{Y}_{i,U} \le \eta_i,$$

$$\tag{4b}$$

$$\gamma_{i,L}(c_{i,L},t) - \gamma_{i,U}(c_{i,U},t) + \gamma_{i,d} \le \eta_i, \tag{4c}$$

$$\dot{\gamma}_{i,l}(c_{i,l},t) - \hat{\mathcal{L}}_l \le \eta_i; \tag{4d}$$
$$\forall (t, u) \in [0, t] \times \mathbf{U}(t) \ \exists i \in [1 \cdot n] \cdot$$

$$\min\{y_i - \gamma_{i,L}(c_{i,L}, t), \gamma_{i,U}(c_{i,U}, t) - y_i\} \le \eta_i;$$
(4e)

$$\forall i = [1; n], \eta_i \le \eta, \tag{4f}$$

$$d_i = [c_{i,L}, c_{i,U}, \eta_i]$$

 $\forall (t, i) \in [0, t_c] \times [1; n]:$

Here, $\ell \in \{L, U\}$, $y(0) \in \prod_{i=1}^{n} [\hat{\mathbf{S}}_{i,L}, \hat{\mathbf{S}}_{i,U}] \subseteq \mathbf{S}$ and $y(t_c) \in \prod_{i=1}^{n} [\hat{\mathbf{T}}_{i,L}, \hat{\mathbf{T}}_{i,U}] \subseteq \mathbf{T}$. Also, $\gamma_{i,d} \in \mathbb{R}^+$ defines a minimum separation between the tubes and $\hat{\mathcal{L}}_{\ell} \in \mathbb{R}^+$ defines the maximum slope of the STTs with respect to time t.

One can readily observe that if the solution to the ROP $\eta^* \leq 0$, then it ensures the conditions in Definition 2.5 will be satisfied.

Remark 3.1 Note that the constraint (4d) on the derivative of tube functions is used to limit abrupt changes in the shape of tubes.

One faces two major challenges to solve the proposed ROP in (4). First, the ROP in (4) has infinitely many constraints since the output space and time are continuous. In addition, though knowledge of the unsafe set is priorly known, constructing the tube avoiding all points in the unsafe set leads to an infinite number of equations. To tackle these challenges, we aim to develop a sampling-based scheme for the construction of the curves that form the tube.

To do so, we consider the augmented unsafe set $\mathbf{W} = [0, t_c] \times \mathbf{U}(t)$. Collect N_t samples $w_r = (t_r, y_r)$ from \mathbf{W} , where $r = [1; N_t]$. Consider a ball \mathbf{W}_r around each sample w_r with radius ϵ , such that, $[0, t_c] \times \mathbf{U}(t) \subseteq \bigcup_{r=1}^{N_t} \mathbf{W}_r$ with: $\|(t, y) - w_r\| \le \epsilon, \forall (t, y) \in \mathbf{W}_r.$ (5)

Now, we construct the Scenario optimization program (SOP) associated with the ROP:

$$\begin{array}{l} \min_{\substack{[d_1,d_2,...,d_n,\eta]}} & \eta \\ \text{s.t.} \\ \forall i \in [1;n] : \gamma_{i,l}(c_{i,l},0) = \hat{\mathbf{S}}_{i,l}, \ \gamma_{i,l}(c_{i,l},t_c) = \hat{\mathbf{T}}_{i,l}; \\ \forall r \in [1;N_t], (t_r,i) \in [0,t_c] \times [1;n] : \end{array}$$
(6a)

$$r \in [1; N_t], (t_r, i) \in [0, t_c] \times [1; n] :$$

$$\mathbf{Y}_{i,L} - \gamma_{i,L} (c_{i,L}, t_r) \le n_i, \gamma_{i,L} (c_{i,L}, t_r) - \mathbf{Y}_{i,L} \le n_i,$$
(6b)

$$\gamma_{i,L}(c_{i,L},t_r) - \gamma_{i,U}(c_{i,U},t_r) + \gamma_{i,d} \le \eta_i,$$
(6c)

$$\dot{\gamma}_{i,j}(c_{i,j}, t_r) - \hat{\mathcal{L}}_j < \eta_j; \tag{6d}$$

$$\forall r \in [1; N_t], (t_r, y_r) \in \mathbf{W}, \exists i \in [1; n]:$$

$$\min\{y_{i,r} - \gamma_{i,L}(c_{i,L}, t_r), \gamma_{i,U}(c_{i,U}, t_r) - y_{i,r}\} \le \eta_i;$$
(6e)

$$\forall i = [1; n], \eta_i \le \eta, \tag{6f}$$

$$a_i = [c_{i,L}, c_{i,U}, \eta_i].$$

Here $y_r = [y_{1,r}, \dots, y_{n,r}]^{\top}$. One can readily observe that SOP in (6) has a finite number of constraints of the same form as (4).

Now, to guarantee that the tubes formed by solving the SOP in (6), fulfill the constraints of ROP in (4), we assume the following:

Assumption 3 $\gamma_{i,L}(c_{i,L},t)$ and $\gamma_{i,U}(c_{i,U},t)$ are Lipschitz continuous with respect to t with Lipschitz constants \mathcal{L}_L and \mathcal{L}_U for all $i \in [1; n]$.

Under Assumption 3, Theorem 3.2 outlines a sampling-based methodology for constructing STTs with a certified confidence of 1.

Theorem 3.2 Under Assumption 3, suppose the SOP in (6) is solved with N_t sampled data as in (5). Let the optimal value of SOP be η_S^* with solution $d_i^* = [c_{i,L}^*, c_{i,U}^*, \eta_i^*] \forall i \in [1; n]$. If

$$\eta_S^* + \mathcal{L}\epsilon \le 0,\tag{7}$$

where $\mathcal{L} = \max{\{\mathcal{L}_L, \mathcal{L}_U, \mathcal{L}_L + \mathcal{L}_U, \mathcal{L}_L + 1, \mathcal{L}_U + 1\}}$, then the STTs functions $\gamma_{i,L}$ and $\gamma_{i,U}$, $\forall i \in [1; n]$, obtained from the SOP in (6) ensures the satisfaction of conditions of Definition 2.5.

Proof 3.3 First, we demonstrate that under condition (7), the $\gamma_{i,L}(t)$ and $\gamma_{i,U}(t)$ constructed through solving the SOP in (6) satisfy Equation (2a). The optimal η_S^* , obtained through solving the (6), guarantees for any $r \in [1; N_t]$, $(t_r, i) \in [0, t_c] \times [1; n]$, we have:

$$\begin{aligned} \mathbf{Y}_{i,L} &- \gamma_{i,L}(c_{i,L}, t_r) \leq \eta_S^*, \\ \gamma_{i,U}(c_{i,L}, t_r) &- \mathbf{Y}_{i,U} \leq \eta_S^*, \\ \gamma_{i,L}(c_{i,L}, t_r) &- \gamma_{i,U}(c_{i,U}, t_r) + \gamma_{i,d} \leq \eta_S^*, \end{aligned}$$

Now from (5), we infer that $\forall t \in [0, t_c], \exists t_r \text{ s.t. } |t - t_r| \leq \epsilon$. Thus, $\forall i \in [1; n], \forall r \in [1; N_t], \forall t \in [0, t_c]$:

(a)
$$\mathbf{Y}_{i,L} - \gamma_{i,L}(c_{i,L},t) = \mathbf{Y}_{i,L} - \gamma_{i,L}(c_{i,L},t_r) + \gamma_{i,L}(c_{i,L},t_r) - \gamma_{i,L}(c_{i,L},t) \le \eta_S^* + \mathcal{L}_L |t - t_r| \le \mathcal{L}\epsilon + \eta_S^* \le 0,$$

$$(b) \ \gamma_{i,U}(c_{i,U},t) - \mathbf{Y}_{i,U} = \gamma_{i,U}(c_{i,U},t) - \gamma_{i,U}(c_{i,U},t_r) + \gamma_{i,U}(c_{i,U},t_r) - \mathbf{Y}_{i,U} \le \mathcal{L}_U |t - t_r| + \eta_S^* \le \mathcal{L}\epsilon + \eta_S^* \le 0,$$

 $\begin{aligned} \text{(c)} \ \ \gamma_{i,L}(c_{i,L},t) &- \gamma_{i,U}(c_{i,U},t) + \gamma_{i,d} \\ &= (\gamma_{i,L}(c_{i,L},t) - \gamma_{i,L}(c_{i,L},t_r)) + (\gamma_{i,L}(c_{i,L},t_r) - \gamma_{i,U}(c_{i,U},t_r) + \gamma_{i,d}) + (\gamma_{i,U}(c_{i,U},t_r) - \gamma_{i,U}(c_{i,U},t)) \\ &\leq \mathcal{L}_L |t - t_r| + \eta_S^* + \mathcal{L}_U |t - t_r| \leq (\mathcal{L}_L + \mathcal{L}_U)\epsilon + \eta_S^* \\ &\leq \mathcal{L}\epsilon + \eta_S^* \leq 0. \end{aligned}$

Next, we show that when the condition in (7) is satisfied, the $\gamma_{i,L}(c_{i,L},t)$ and $\gamma_{i,U}(c_{i,U},t)$ formulated by solving the SOP in (6) satisfy argument (2d). The optimal η_i^* , obtained from solving the SOP in (6), also ensures that for any $r \in [1; N_t], (t_r, y_r) \in \mathbf{W}$, $\min \{y_{i,r} - \gamma_{i,L}(c_{i,L},t_r), \gamma_{i,U}(c_{i,U},t_r) - y_{i,r}\} \leq \eta_i^*$. Now, $\forall i \in [1; n], \forall r \in [1; N_t], \forall t \in [0, t_c], \forall y_i \in \mathbf{U}(t)$:

$$\begin{aligned} y_{i} - \gamma_{i,L}(c_{i,L},t) \\ &= (y_{i} - y_{i,r}) + (y_{i,r} - \gamma_{i,L}(c_{i,L},t_{r})) + \left(\gamma_{i,L}(c_{i,L},t_{r}) - \gamma_{i,L}(c_{i,L},t)\right) \leq \epsilon + \eta_{i}^{*} + \mathcal{L}_{L}|t - t_{r}| \\ &\leq (\mathcal{L}_{L} + 1)\epsilon + \eta_{S}^{*} \leq \mathcal{L}\epsilon + \eta_{S}^{*} \leq 0 \\ Or \\ &\gamma_{i,U}(c_{i,U},t) - y_{i} \\ &= (y_{i,r} - y_{i}) + (\gamma_{i,U}(c_{i,U},t_{r}) - y_{i,r}) + \left(\gamma_{i,U}(c_{i,U},t) - \gamma_{i,U}(c_{i,U},t_{r})\right) \leq \epsilon + \eta_{i}^{*} + \mathcal{L}_{U}|t - t_{r}| \end{aligned}$$

Therefore, if the condition in (7) is met, the STT constructed with boundaries defined by $\gamma_{i,L}(c_{i,L},t)$ and $\gamma_{i,U}(c_{i,U},t)$, for all $i \in [1; n]$ as determined by solving the SOP in (6) satisfies Definition 2.5, thereby completing the proof.

Remark 3.4 Note that the Lipschitz constants \mathcal{L}_L and \mathcal{L}_U are required to check condition (7) in Theorem 3.2. We introduce Algorithm 1 to estimate these Lipschitz constants in Appendix A, which follows the similar procedure as [36, Algorithm 1] and [37, Algorithm 2].

Remark 3.5 The basis functions $p_{i,l}^k$ that shape the STTs are highly flexible and can be chosen in various forms, such as monomials in t for a polynomial-type STT. Unlike CBFs, which depend on the multi-dimensional state variable x [36], STTs rely solely on t, significantly reducing computational complexity. Additionally, data-driven CBF synthesis requires sampling from the system's dynamics, whereas the sampling-based STT approach only requires data samples from time and the unsafe set, simplifying the data collection process.

The computational complexity of the SOP depends on factors like the choice of basis functions and the sampling density. Notably, in complex environments, with a greater number of unsafe sets, higher-degree polynomials provide greater flexibility but also increase the number of decision variables, leading to a polynomial growth in computation time. Similarly, finer sampling in time and unsafe regions adds more constraints to the SOP, further contributing to a polynomial increase in computational demand. The change in computational complexity with the number of decision variables and constraints is illustrated in Figure 1. However, it is important to note that the tube computation is performed offline and does not affect the real-time implementation of the STT, which relies on a closed-form control law, discussed in the next section.

4 Controller Design

 $\leq (\mathcal{L}_U + 1)\epsilon + \eta_S^* \leq \mathcal{L}\epsilon + \eta_S^* \leq 0.$

In this section, we use the STTs developed through the sampling-based approach outlined in (6) to derive an approximation-free, closed-form control law to constrain the output of system (1) within the tubes. The lower triangular structure of (1) allows us to use a backstepping-like design approach similar to that described in [41]. First, we design an intermediate control input r_2 for the x_1 dynamics to ensure the fulfillment of (3). We then iteratively design the intermediate control laws r_{k+1} for the x_k dynamics, ensuring x_k tracks r_k , for all $k \in [2; N]$. It is important to note that r_{N+1} effectively becomes the actual control input u for the system. The steps of the controller design are outlined below.

Figure 1: Time complexity

Stage 1: Given $\gamma_{1,i,L}(c_{i,L},t)$ and $\gamma_{1,i,U}(c_{i,U},t)$, $i \in [1; n]$, define the normalized error $e_1(x_1, t)$, the transformed error $\varepsilon_1(x_1, t)$ and the diagonal matrix $\xi_1(x_1, t)$ as

$$e_1(x_1,t) = [e_{1,1}(x_{1,1},t),\dots,e_{1,n}(x_{1,n},t)]^\top = (\gamma_{1,d}(t))^{-1} (2x_1 - \gamma_{1,s}(t)),$$
(8a)

$$\varepsilon_1(x_1,t) = \left[\ln\left(\frac{1+e_{1,1}(x_{1,1},t)}{1-e_{1,1}(x_{1,1},t)}\right), \dots, \ln\left(\frac{1+e_{1,n}(x_{1,n},t)}{1-e_{1,n}(x_{1,n},t)}\right)\right]^{\top},\tag{8b}$$

$$\xi_1(x_1,t) = \frac{4(\eta_1,d(t))}{1 - e_1^{\mathsf{T}}(x_1,t)e_1(x_1,t)},\tag{8c}$$

where, $\gamma_{1,s} := [\gamma_{1,1,U} + \gamma_{1,1,L}, \dots, \gamma_{1,n,U} + \gamma_{1,n,L}]^{\top}$ and $\gamma_{1,d} := \text{diag}(\gamma_{1,1,d}, \dots, \gamma_{1,n,d})$, with $\gamma_{1,i,d} = \gamma_{1,i,U} - \gamma_{1,i,L}$. The intermediate control input $r_2(x_1, t)$ is given by:

$$r_2(x_1,t) = -\kappa_1 \varepsilon_1(x_1,t) \xi_1(x_1,t), \kappa_1 \in \mathbb{R}^+.$$

Stage k ($k \in [2; N]$): Given the reference vector $r_k(z_k, t)$, we aim to design the subsequent intermediate control $r_{k+1}(z_{k+1}, t)$ for the dynamics of x_{k+1} , ensuring that x_{k+1} tracks the trajectory determined by $r_k(z_k, t)$. Here, $z_k = [x_1, x_2, \ldots, x_{k-1}]^{\top}$.

This is done by enforcing exponentially narrowing constraint $\gamma_{k,i}(t) = (p_{k,i} - q_{k,i})e^{-\mu_{k,i}t} + q_{k,i}$, such that

$$-\gamma_{k,i}(t) \le (x_{k,i} - r_{k,i}) \le \gamma_{k,i}(t) \ \forall (t,i) \in \mathbb{R}^+_0 \times [1;n].$$

Here, $\mu_{k,i} \in \mathbb{R}_0^+$, and $p_{k,i}, q_{k,i} \in \mathbb{R}^+$ with $p_{k,i} > q_{k,i}$ and $|x_{k,i}(t=0) - r_{k,i}(t=0)| \le p_{k,i}$. Now define the normalized error $e_k(x_k, t)$, the transformed error $\varepsilon_k(x_k, t)$ and the diagonal matrix $\xi_k(x_k, t)$ as

$$e_k(x_k,t) = [e_{k,1}(x_{k,1},t),\dots,e_{k,n}(x_{k,n},t)]^{\top} = (\gamma_{k,d}(t))^{-1} (x_k - r_k),$$
(9a)

$$\varepsilon_k(x_k, t) = \left[\ln \left(\frac{1 + e_{k,1}(x_{k,1}, t)}{1 - e_{k,1}(x_{k,1}, t)} \right), \dots, \ln \left(\frac{1 + e_{k,n}(x_{k,n}, t)}{1 - e_{k,n}(x_{k,n}, t)} \right) \right]^\top,$$
(9b)

$$\xi_k(x_k, t) = \frac{4(\gamma_{k,d}(t))^{-1}}{1 - e_k^\top(x_k, t)e_k(x_k, t)},$$
(9c)

where $\gamma_{k,d} := \operatorname{diag}(\gamma_{k,1,d}, \ldots, \gamma_{k,n,d})$, with $\gamma_{k,i,d} = \frac{1}{2}(\gamma_{k,i,U} - \gamma_{k,i,L}) = \gamma_{k,i}, \forall i \in [1;n]$.

So, the intermediate control inputs $r_{k+1}(z_{k+1},t)$ to enforce the desired temporal reach-avoid-stay task is given by

$$r_{k+1}(z_{k+1},t) = -\kappa_k \varepsilon_k(x_k,t) \xi_k(x_k,t), \kappa_k \in \mathbb{R}^+$$

Note that, at the N-th stage, $r_{N+1}(z_{N+1}, t)$ essentially serves as the actual control input u, which is given by,

$$u(z_{N+1},t) = -\kappa_N \varepsilon_N(x_N,t) \xi_N(x_N,t), \kappa_N \in \mathbb{R}^+.$$

Thus, we can design the control input to perform the T-RAS specification for the system described in (1).

Theorem 4.1 Given a nonlinear MIMO system in (1) satisfying assumptions 1 and 2, a temporal reach-avoid-stay (*T*-RAS) task as defined in Definition 2.2, and a spatio-temporal tube as discussed in Section 3, if the initial state $x_k(0)$ is within the STTs at time t = 0, i.e., $\gamma_{k,i,L}(0) < x_{k,i}(0) < \gamma_{k,i,U}(0), \forall i \in [1; n], \forall k \in [1; N]$, then the closed-form control strategies,

$$r_{k+1}(z_{k+1},t) = -\kappa_k \varepsilon_k(x_k,t) \xi_k(x_k,t), k \in [1; N-1],$$
(10a)

$$u(z_{N+1},t) = -\kappa_N \varepsilon_N(x_N,t) \xi_N(x_N,t), \tag{10b}$$

will ensure the satisfaction of given temporal reach-avoid-stay task where $z_{k+1} = [x_1, x_2, \dots, x_k]^\top$ and ε_k , ξ_k are shown in (8) and (9).

Proof 4.2 The proof is done for the stages mentioned above. First, we prove the control law for the STT, and then we sequentially prove it for the other stages.

In each stage, the proof proceeds in three steps. First, we show that there exists a maximal solution for the normalized error $e_k : [0, \tau_{\max}] \to \mathbb{D}$, which implies that $e_k(x_k, t)$ remains within \mathbb{D} in the maximal time solution interval $[0, \tau_{\max})$. Next, we show that the proposed control law in (10) constraints $e_k(x_k, t)$ to a compact subset of \mathbb{D} . Finally, we prove that τ_{\max} can be extended to ∞ .

Stage 1: Differentiating the normalized error $e_1(x_1, t)$ w.r.t time and substituting the first equation of the system dynamics (1) we get,

$$\dot{e}_1 = 2(\gamma_{1,d}(t))^{-1} \left(f_1(x_1) + g_1(x_1)x_2 + w_1 - \frac{1}{2}(\dot{\gamma}_{1,s}(t) + \dot{\gamma}_{1,d}(t)e_1) \right) := h_1(t,e_1),$$

where $x_1 = \frac{\gamma_{1,d}(t)e_1 + \gamma_{1,s}(t)}{2}$. We also define the constraints for e_1 through the open and bounded set $\mathbb{D} := (-1, 1)^n$.

<u>Step (i)</u>: Since the initial state $x_1(0)$ satisfies $\gamma_{1,i,L}(0) < x_{1,i}(0) < \gamma_{1,i,U}(0), \forall i \in [1; n]$, the initial normalized error $\overline{e_1(0)}$ is also within the constrained region \mathbb{D} . Further, the STTs are bounded and continuously differentiable functions of time, the functions $f_1(x_1)$ and $g_1(x_1)$ are locally Lipschitz and the control law $r_2(x_1, t)$ is smooth over \mathbb{D} . As a consequence, $h_1(t, e_1)$ is bounded and continuously differentiable on t and locally Lipschitz on e_1 over \mathbb{D} .

Therefore, according to [42, Theorem 54], there exists a maximal solution to the initial value problem $\dot{e}_1 = h_1(t, e_1), e_1(0) \in \mathbb{D}$ on the time interval $[0, \tau_{\max})$ such that $e_1(t) \in \mathbb{D}, \forall t \in [0, \tau_{\max})$.

<u>Step (ii)</u>: Consider the following positive definite and radially unbounded Lyapunov function candidate: $V_1 = \frac{1}{2} \varepsilon_1^\top \varepsilon_1$. Differentiating V_1 with respect to t and substituting $\dot{\varepsilon_1}$, $\dot{e_1}$, system dynamics (1), and the control strategy (10), we have:

$$\dot{V}_{1} = \varepsilon_{1}^{T} \dot{\varepsilon}_{1} = \varepsilon_{1}^{T} \frac{2}{1 - e_{1}^{T} e_{1}} \dot{e}_{1} = \varepsilon_{1}^{T} \xi_{1} \left(\dot{x}_{1} - \frac{1}{2} (\dot{\gamma}_{1,s} + \dot{\gamma}_{1,d} e_{1}) \right)$$
$$= \varepsilon_{1}^{T} \xi_{1} \left(f_{1}(x_{1}) + g_{1}(x_{1}) x_{2} + w_{1} - \frac{1}{2} (\dot{\gamma}_{1,s} + \dot{\gamma}_{1,d} e_{1}) \right),$$
$$= \varepsilon_{1}^{T} \xi_{1} \left(f_{1}(x_{1}) - \kappa_{1} g_{1}(x_{1}) \xi_{1} \varepsilon_{1} + w_{1} - \frac{1}{2} (\dot{\gamma}_{1,s} + \dot{\gamma}_{1,d} e_{1}) \right)$$

Using Rayleigh-Ritz inequality and Assumption 2,

$$\underline{g_1} \|\varepsilon_1\|^2 \|\xi_1\|^2 \le \lambda_{\min}(g_1(x_1)) \|\varepsilon_1\|^2 \|\xi_1\|^2 \le \varepsilon_1^\top \xi_1 g_1(x_1) \xi_1 \varepsilon_1, -\kappa_1 \varepsilon_1^\top \xi_1 g_1(x_1) \xi_1 \varepsilon_1 \le -\kappa_1 g_1 \|\varepsilon_1\|^2 \|\xi_1\|^2 = -\kappa_q^1 \|\varepsilon_1\|^2 \|\xi_1\|^2.$$

Therefore, $\dot{V}_1 \leq -\kappa_g^1 \|\varepsilon_1\|^2 \|\xi_1\|^2 + \|\varepsilon_1\| \|\xi_1\| \|\Phi_1\|,$

where $\Phi_1 := f_1(x_1) + w_1 - \frac{1}{2}\dot{\gamma}_{1,s} - \frac{1}{2}\dot{\gamma}_{1,d}e_1$. From the construction of $\gamma_{1,s}, \gamma_{1,d}$ we know that $\dot{\gamma}_{1,s}$ and $\dot{\gamma}_{1,d}$ are bounded by construction. From step 1, we have $e_1(t) \in \mathbb{D}$ and consequently $\forall i \in [1; n], x_{1,i}(t) \in (\gamma_{1,i,L}(t), \gamma_{1,i,U}(t))$. Thus, owing to the continuity of $f_1(x_1)$ and employing the extreme value theorem, we can infer $||f_1(x_1)|| < \infty$. Hence, $||\Phi_1|| < \infty, \forall t \in [0, \tau_{max})$.

Now add and substract $\kappa_a^1 \theta \|\varepsilon_1\|^2 \|\xi_1\|^2$, where $\theta \in (0, 1)$.

$$\begin{split} \dot{V}_{1} &\leq -\kappa_{g}^{1}(1-\theta) \left\|\varepsilon_{1}\right\|^{2} \left\|\xi_{1}\right\|^{2} - \left\|\varepsilon_{1}\right\| \left\|\xi_{1}\right\| \left(\kappa_{g}^{1}\theta \left\|\varepsilon_{1}\right\| \left\|\xi_{1}\right\| - \left\|\Phi_{1}\right\|\right) \\ &\leq -\kappa_{g}^{1}(1-\theta) \left\|\varepsilon_{1}\right\|^{2} \left\|\xi_{1}\right\|^{2}, \forall \kappa_{g}^{1}\theta \left\|\varepsilon_{1}\right\| \left\|\xi_{1}\right\| - \left\|\Phi_{1}\right\| \geq 0 \\ &\leq -\kappa_{g}^{1}(1-\theta) \left\|\varepsilon_{1}\right\|^{2} \left\|\xi_{1}\right\|^{2}, \forall \left\|\varepsilon_{1}\right\| \geq \frac{\left\|\Phi_{1}\right\|}{\kappa_{g}^{1}\theta \left\|\xi_{1}\right\|}, \forall t \in [0, \tau_{\max}). \end{split}$$

Therefore, we can conclude that there exists a time-independent upper bound $\varepsilon_1^* \in \mathbb{R}_0^+$ to the transformed error ε_1 , i.e., $\|\varepsilon_1\| \leq \varepsilon_1^*, \forall t \in [0, \tau_{\max}).$

Consequently, taking inverse logarithmic function,

$$-1 < \frac{e_{1,i}^{-\varepsilon_{1,i}^*} - 1}{e_{1,i}^{-\varepsilon_{1,i}^*} + 1} =: e_{1,i,L} \le e_{1,i} \le e_{1,i,U} := \frac{e_{1,i}^{\varepsilon_{1,i}^*} - 1}{e_{1,i}^{\varepsilon_{1,i}^*} + 1} < 1, \forall t \in [0, \tau_{\max}), \text{ for } i \in [1; n].$$

Therefore, by employing the control law (10), we can constrain e_1 to a compact subset of \mathbb{D} as:

$$e_1(t) \in [e_{1,L}, e_{1,U}] =: \mathbb{D}' \subset \mathbb{D}, \forall t \in [0, \tau_{\max}),$$

where $e_{1,L} = [e_{1,1,L}, \dots, e_{1,n,L}]^\top$ and $e_{1,U} = [e_{1,1,U}, \dots, e_{1,n,U}]^\top.$

<u>Step (iii)</u>: Finally, we prove τ_{\max} can be extended to ∞ . We know that $e_1(t) \in \mathbb{D}', \forall t \in [0, \tau_{\max})$, where \mathbb{D}' is a non-empty compact subset of \mathbb{D} . However, if $\tau_{\max} < \infty$ then according to [42, Proposition C.3.6], $\exists t' \in [0, \tau_{\max})$ such that $e_1(t) \notin \mathbb{D}$. This leads to a contradiction! Hence, we conclude that τ_{\max} can be extended to ∞ .

Stage k ($k \in [2; N]$):

Differentiating the normalized error $e_k(x_k, t)$ with respect to time and substituting the corresponding equations of the system dynamics (1), we get

$$\dot{e_k} = (\gamma_{k,d}(t))^{-1} (f_k(x_k) + g_k(x_k)x_{k+1} + w_k - (\dot{r}_k(z_k,t) + \dot{\gamma}_{k,d}(t)e_k)) := h_k(t,e_k)$$

We also define the constraints for e_k through the open and bounded set $\mathbb{D} := (-1, 1)^n$.

<u>Step (i)</u>: Since the initial state $x_k(0)$ satisfies $-\gamma_{k,i}(0) < x_{k,i}(0) < \gamma_{k,i}(0), \forall i \in [1; n]$, the initial normalized error $\overline{e_k(0)}$ is also within the constrained region \mathbb{D} . Further, the STTs are bounded and continuously differentiable functions of time, the functions $f_k(x_k)$ and $g_k(x_k)$ are locally Lipschitz and the control law $r_{k+1}(z_{k+1}, t)$ is smooth over \mathbb{D} . As a consequence, $h_k(t, e_k)$ is bounded and continuously differentiable on t and locally Lipschitz on e_k over \mathbb{D} .

Therefore, according to [42, Theorem 54], there exists a maximal solution to the initial value problem $\dot{e_k} = h_k(t, e_k), e_k(0) \in \mathbb{D}$ on the time interval $[0, \tau_{\max})$ such that $e_k(t) \in \mathbb{D}, \forall t \in [0, \tau_{\max})$.

<u>Step (ii)</u>: Consider the following positive definite and radially unbounded Lyapunov function candidate: $V_k = \frac{1}{2} \varepsilon_k^\top \varepsilon_k$. Differentiating V_k with respect to t and substituting $\dot{\varepsilon}_k$, $\dot{\varepsilon}_k$, system dynamics (1), and the control strategy (10), we obtain:

$$\begin{split} \dot{V}_k &= \varepsilon_k^T \dot{\varepsilon}_k = \varepsilon_k^T \frac{2}{1 - e_k^T e_k} \dot{e}_k \\ &= \frac{1}{2} \varepsilon_k^T \xi_k \left(\dot{x}_k - \dot{r}_k(z_k, t) - \dot{\gamma}_{k,d} e_k \right) \\ &= \frac{1}{2} \varepsilon_k^T \xi_k \left(f_k(x_k) + g_k(x_k) x_{k+1} + w_k - \dot{r}_k(z_k, t) - \dot{\gamma}_{k,d} e_k \right) \\ &= \frac{1}{2} \varepsilon_k^T \xi_k \left(f_k(x_k) - \kappa_k g_k(x_k) \xi_k \varepsilon_k + w_k - \dot{r}_k(z_k, t) - \dot{\gamma}_{k,d} e_k \right). \end{split}$$

Using Rayleigh-Ritz inequality and Assumption 2,

$$\frac{g_k}{\|\varepsilon_k\|^2} \|\xi_k\|^2 \leq \lambda_{\min}(g_k(x_k)) \|\varepsilon_k\|^2 \|\xi_k\|^2 \leq \varepsilon_k^\top \xi_k g_k(x_k) \xi_k \varepsilon_k, \\
\implies -\frac{1}{2} \kappa_k \varepsilon_k^\top \xi_k g_k(x_k) \xi_k \varepsilon_k \leq -\frac{1}{2} \kappa_k \underline{g_k} \|\varepsilon_k\|^2 \|\xi_k\|^2 = -\kappa_g^k \|\varepsilon_k\|^2 \|\xi_k\|^2.$$

Therefore, $\dot{V}_k \leq -\kappa_g^k \|\varepsilon_k\|^2 \|\xi_k\|^2 + \|\varepsilon_k\| \|\xi_k\| \|\Phi_k\|$, where $\Phi_k := \frac{1}{2} (f_k(x_k) + w_k - \dot{r}_k(z_k, t) - \dot{\gamma}_{k,d}e_k)$. From the construction of $\gamma_{k,d}$ we know that $\dot{\gamma}_{k,d}$ is bounded. From step k-a, we have $e_k(t) \in \mathbb{D}$ and consequently $\forall i \in [1; n]$, $x_{k,i}(t) \in (-\gamma_{k,i}(t), \gamma_{k,i}(t))$. Thus, owing to the continuity of $f_k(x_k)$ and employing the extreme value theorem, we can infer $\|f_k(x_k)\| < \infty$. Also, since r_k is bounded, we can say that \dot{r}_k is bounded. Hence, $\|\Phi_k\| < \infty, \forall t \in [0, \tau_{max})$.

Now add and substract $\kappa_a^k \theta \|\varepsilon_k\|^2 \|\xi_k\|^2$, where $\theta \in (0, 1)$.

$$\begin{split} \dot{V}_{k} &\leq -\kappa_{g}^{k}(1-\theta) \|\varepsilon_{k}\|^{2} \|\xi_{k}\|^{2} - \|\varepsilon_{k}\| \|\xi_{k}\| \left(\kappa_{g}^{k}\theta \|\varepsilon_{k}\| \|\xi_{k}\| - \|\Phi_{k}\|\right) \\ &\leq -\kappa_{g}^{k}(1-\theta) \|\varepsilon_{k}\|^{2} \|\xi_{k}\|^{2}, \forall \kappa_{g}^{k}\theta \|\varepsilon_{k}\| \|\xi_{k}\| - \|\Phi_{k}\| \geq 0 \\ &\leq -\kappa_{g}^{k}(1-\theta) \|\varepsilon_{k}\|^{2} \|\xi_{k}\|^{2}, \forall \|\varepsilon_{k}\| \geq \frac{\|\Phi_{k}\|}{\kappa_{g}^{k}\theta \|\xi_{k}\|}, \ \forall t \in [0, \tau_{\max}). \end{split}$$

Therefore, we can conclude that there exists a time-independent upper bound $\varepsilon_k^* \in \mathbb{R}_0^+$ to the transformed error ε_k , i.e., $\|\varepsilon_k\| \leq \varepsilon_k^*, \forall t \in [0, \tau_{\max}).$

Consequently, taking inverse logarithmic function,

$$-1 < \frac{e_{k,i}^{-\varepsilon_{k,i}^*} - 1}{e_{k,i}^{-\varepsilon_{k,i}^*} + 1} =: e_{k,i,L} \le e_{k,i} \le e_{k,i,U} := \frac{e_{k,i}^{\varepsilon_{k,i}^*} - 1}{e_{k,i}^{\varepsilon_{k,i}^*} + 1} < 1, \ \forall t \in [0, \tau_{\max}), \ \text{for } i \in [1; n].$$

Therefore, by employing the control law (10), we can constrain e_k to a compact subset of \mathbb{D} as:

 $e_k(t) \in [e_{k,L}, e_{k,U}] =: \mathbb{D}' \subset \mathbb{D}, \forall t \in [0, \tau_{\max}),$

where, $e_{k,L} = [e_{k,1,L}, \dots, e_{k,n,L}]^{\top}$ and $e_{k,U} = [e_{k,1,U}, \dots, e_{k,n,U}]^{\top}$.

<u>Step (iii)</u>: Finally, we prove τ_{\max} can be extended to ∞ . We know that $e_k(t) \in \mathbb{D}', \forall t \in [0, \tau_{\max})$, where \mathbb{D}' is a non-empty compact subset of \mathbb{D} . However, if $\tau_{\max} < \infty$ then according to [42, Proposition C.3.6], $\exists t' \in [0, \tau_{\max})$ such that $e_k(t) \notin \mathbb{D}$. This leads to a contradiction! Hence, we conclude that τ_{\max} can be extended to ∞ .

Thus, the control strategy in (10) solves the T-RAS task as mentioned in Definition 2.2, hence completing the proof.

Remark 4.3 Note that the closed-form time-dependent control law (10) is approximation-free and guarantees the satisfaction of T-RAS specifications for control affine MIMO pure-feedback systems with unknown dynamics.

5 Case Study

To show the effectiveness of our approach to constructing the STT-based controllers for the temporal reach-avoid-stay tasks, we consider three different case studies: (i) an omnidirectional robot, (ii) a 2-link manipulator, and (iii) a magnetic levitator system.

5.1 Omnidirectional Robot

Consider the omnidirectional robot adopted from [3] and defined as

$$\begin{bmatrix} \dot{x}_1\\ \dot{x}_2\\ \dot{x}_3 \end{bmatrix} = \begin{bmatrix} \cos x_3 & -\sin x_3 & 0\\ \sin x_3 & \cos x_3 & 0\\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} v_1\\ v_2\\ \omega \end{bmatrix} + w(t),$$
(11)

where the state vector $[x_1, x_2, x_3]^{\top}$ captures the robot's pose, $[v_1, v_2, \omega]^{\top}$ is the input velocity vector in the robot's frame, and w is an external disturbance, with output of the system being $y = [x_1, x_2]^{\top}$.

The robot is operating in a 2D environment with obstacles in the presence of unknown bounded external disturbance. The unsafe set covers the start zone (*i.e.*, initial state) and goal (*i.e.*, target state) in such a way that the adaptive tube proposed in [33] can not be framed from the initial state to the target set, avoiding the unsafe region.

The starting zone of the robot is $\mathbf{S} = [1, 1.5] \times [2, 2.5]$ while the target region is $\mathbf{T} = [4.5, 5] \times [4.5, 5]$. The time bound for reaching the target is considered as $t_c = 5$. The unsafe set (red colored), as shown in Figure 2(a), is assumed to present at the same location for the complete time-horizon $[0, t_c]$. As discussed in Section 3, we consider the template

Figure 2: (a) (b) Trajectory of omnidirectional robot navigating 2D environments (top) and respective STTs (bottom) (c) Trajectory of 2R manipulator (top) and respective STTs (bottom).

for the STTs as second-order polynomials in time t: $p_{i,l}(t) = \{1, t, t^2\}$, for $l = \{L, U\}$. The STT obtained to solve the T-RAS task for this case is given by the following curves:

 $\gamma_{1,L}(c_{1,L},t) = 1 + 0.2377t + 0.0925t^2,$ $\gamma_{1,U}(c_{1,U},t) = 1.5 - 0.0023t + 0.1405t^2,$ $\gamma_{2,L}(c_{2,L},t) = 2 - 1.9782t + 0.4956t^2,$ $\gamma_{2,U}(c_{2,U},t) = 2.5 - 2.2183t + 0.5437t^2.$

The Lipschitz constants \mathcal{L}_L and \mathcal{L}_U are estimated to be 2.93 and 3.17, respectively, so $\mathcal{L} = 6.1$ and ϵ is considered as 0.0005. We have used the Z3 SMT solver [43] to solve the scenario optimization problem (6). The η_S^* upon solving the SOP is -0.1, which essentially means $\eta_S^* + \mathcal{L}\epsilon = -0.1 + 6.1 \times 0.0005 = -0.09695 < 0$, that follows Theorem 3.2. The computation time to compute the STTs via solving SOP in (6) is 6.58 seconds with 2000 sample points.

The trajectory of the robot under the influence of the proposed control law in (10) as well as the obtained STTs in each dimension are shown in Figure 2(a).

We consider another case where the starting zone of the robot is $\mathbf{S} = [0, 0.5] \times [0, 0.5]$ while the target is located at the zone $\mathbf{T} = [4.5, 5] \times [4.5, 5]$. The time required to reach the target $t_c = 10$. The unsafe set, as shown in Figure 2(b), is present in the same location for the complete time horizon $[0, t_c]$. Here, we consider the template for the STTs as third-order polynomials in time t: $p_{i,l}(t) = \{1, t, t^2, t^3\}$, for $l = \{L, U\}$. The STTs obtained to solve the T-RAS task for this case are given by the following curves:

$$\begin{split} \gamma_{1,L}(c_{1,L},t) &= 3.9463t - 0.9857t^2 + 0.0636t^3, \\ \gamma_{1,U}(c_{1,U},t) &= 0.5 + 3.8711t - 0.9928t^2 + 0.0651t^3, \\ \gamma_{2,L}(c_{2,L},t) &= 0.4283t - 0.0009t^2 + 0.0001t^3, \\ \gamma_{2,U}(c_{2,U},t) &= 0.5 + 0.1945t + 0.0422t^2 - 0.0017t^3. \end{split}$$

The trajectory of the robot under the influence of the proposed control law in (10) as well as the obtained STTs in each dimension are shown in Figure 2(b).

5.2 Euler-Lagrange System

For a second example, we consider a two-link 2R SCARA manipulator adapted from [48]. The system operates via two rotating joints, with the joint angles represented by θ_1 and θ_2 . We define the system's output at any time as $y(t) = [\theta_1(t), \theta_2(t)]^\top$. Using the STT approach, we ensure that the system trajectory starting from the initial output

Figure 3: Temporal evolution of magnetic levitation system using the control law in (10) (left) and respective STTs for T-RAS tasks (right).

Table 1: Comparing STTs with classical algorithms						
Algorithm	Closed-form	Formal	Prescribed-time	Unknown	Bounded	Time dependent
	Control	Guarantee	Reachability	Dynamics	Disturbance	Obstacle
RRT* [44]	_1	X	_1	1	_1	1
MPC [45] [46]	1	1	X	X	X	1
CBF-based methods [12] [14]	×	1	×	×	×	1
HJ-based reachability [17]	×	1	×	×	1	1
NN control [21]	×	X	1	1	X	X
Symbolic Control [47]	×	1	×	×	×	×
STT	1	1	1	1	1	1

¹ Additional mechanisms, are required to ensure control, satisfy reachability within the prescribed time, and handle bounded disturbances.

 $\mathbf{S} = [\frac{\pi}{6}, 0]^{\top}$, reaches the target output $\mathbf{T} = [\frac{5\pi}{6}, 0]^{\top}$, bypassing the unsafe sets shown in Figure 2(c). The unsafe set is present for the complete time-horizon $[0, t_c]$ with $t_c = 5$. Note that to design the STTs, the obstacle in the workspace has to be mapped to an equivalent unsafe set in the state space. The following describes the model used:

$$ml^{2} \begin{bmatrix} \frac{5}{3} + c_{2} & \frac{1}{3} + \frac{1}{2}c_{2} \\ \frac{1}{3} + \frac{1}{2}c_{2} & \frac{1}{3} \end{bmatrix} \begin{bmatrix} \ddot{\theta}_{1} \\ \ddot{\theta}_{2} \end{bmatrix} + ml^{2}s_{2} \begin{bmatrix} -\frac{1}{2}\dot{\theta}_{2}^{2} - \dot{\theta}_{1}\dot{\theta}_{2} \\ \frac{1}{2}\dot{\theta}_{2}^{2} \end{bmatrix} + mgl \begin{bmatrix} \frac{3}{2}c_{1} + \frac{1}{2}c_{12} \\ \frac{1}{2}c_{12} \end{bmatrix} = \begin{bmatrix} \tau_{1}(t) \\ \tau_{2}(t) \end{bmatrix} + d(t)$$

where m = 1kg and l = 1m are the mass and length of each link, $g = 9.8m/s^2$ is the acceleration due to gravity, $\tau_1(t), \tau_2(t)$ are the torque inputs at the joints, d(t) is an unknown bounded disturbance, $c_1 = \cos \theta_1$, $c_2 = \cos \theta_2$, $s_2 = \sin \theta_2$, and $c_{12} = \cos (\theta_1 + \theta_2)$.

Here, we consider the template for the STTs as second-order polynomials in time t: $p_{i,l}(t) = \{1, t, t^2\}$, for $l = \{L, U\}$. The STTs obtained to solve the T-RAS task for this case are given by the following curves:

$$\gamma_{1,L}(c_{1,L},t) = 0.3236 - 0.0893t + 0.1016t^2,$$

$$\gamma_{1,U}(c_{1,U},t) = 0.7236 - 0.3293t + 0.1496t^2,$$

$$\gamma_{2,L}(c_{2,L},t) = -0.2002 + 1.4496t - 0.2899t^2,$$

$$\gamma_{2,U}(c_{2,U},t) = 0.2000 + 1.2097t - 0.2419t^2.$$

The Lipschitz constants \mathcal{L}_L and \mathcal{L}_U are estimated to be 1.408 and 1.215, respectively, so $\mathcal{L} = 2.623$ and for $\epsilon = 0.00002$, the η_S^* upon solving the SOP is -0.0001, which essentially means $\eta_S^* + \mathcal{L}\epsilon = -0.0001 + 2.623 \times 0.00002 = -0.0000475 < 0$, that follows Theorem 3.2. The computation time to compute the STTs is 206 seconds with 40500 sample points.

The simulation results with the proposed control law in (10), as well as the obtained STTs in each dimension, are depicted in Figure 2(c).

5.3 Magnetic Levitator System

Consider the magnetic levitator system adopted from [49] and defined as:

$$\dot{x}_1 = \frac{x_2}{M}, \dot{x}_2 = \frac{x_3}{2\alpha} - Mg, \dot{x}_3 = -\frac{2R}{\alpha}(1-x_1)x_3 + 2\sqrt{x_3}u_3$$

where the states x_1, x_2, x_3 denote the ball's position, the momentum of the ball and the square of the flux linkage associated with the electromagnet, respectively with output $y = x_1$. Also, M = 1 represents the mass of the ball, q = 9.8 stands for acceleration due to gravity, R = 10 denotes coil resistance around the electromagnet, $\alpha = 0.5$ is a positive constant that depends on the number of coil turns, and u represents the voltage applied to the electromagnet. The system is expected to avoid timed obstacles, keeping initial and target regions the same. The start and target region are considered to be the same and are $\mathbf{S} = \mathbf{T} = [0.75, 1.25]$. To simulate the time-dependent obstacle, we assume that the obstacle moves from right to left and it will have a possible collision during the time interval [1.5,3.5]. The time-dependent unsafe set is defined by

$$\mathbf{U}(t) = \begin{cases} [0,3], & \text{if } t \in [1.5,3.5], \\ \phi, & \text{elsewhere,} \end{cases}$$

where ϕ represents empty set.

Here, we consider the template for the STTs as second-order polynomials in time t: $p_{i,l}(t) = \{1, t, t^2\}$, for $l = \{L, U\}$. The STT obtained to solve the T-RAS task for this case is given by the following curves:

$$\gamma_{1,L}(c_{1,L},t) = 0.75 + 2.7167t - 0.5433t^2,$$

$$\gamma_{1,U}(c_{1,U},t) = 1.25 + 2.6447t - 0.5289t^2.$$

The simulation result with the proposed control law in (10), as well as the obtained STT, are shown in Figure 3.

5.4 Drones

We consider the state of the drone, adapted from [50], is given by the following equation:

$$\begin{split} & [\dot{x}_1, \dot{x}_2, \dot{x}_3]^\top = [v_x, v_y, v_z]^\top + w_1(t), \\ & [\dot{v}_x, \dot{v}_y, \dot{v}_z]^\top = [u_x, u_y, u_z]^\top + w_2(t), \end{split}$$

where $[x_1, x_2, x_3]^{\top}$ captures the position of the drone, $[v_x, v_y, v_z]^{\top}$ is the velocity of the drone and $[u_x, u_y, u_z]^{\top}$ is the control input of the drone.

We consider the drone to be diagonally moving in an arena given by $[0,3] \times [0,3] \times [0,15]$, starting from S = $[2.75,3] \times [2.75,3] \times [0,0.25]$ reaching towards the target $\mathbf{T} = [0,0.25] \times [0,0.25] \times [0,0.25]$, avoiding the static unsafe set given by $\mathbf{U} = [1, 2] \times [0, 3] \times [0, 3]$ which is assumed to be present there for the complete time-horizon. The time bound for reaching the target is considered as $t_c = 20$. We consider another dynamic cubic obstacle with a uniform width of 0.25m along each dimension. This obstacle moves along the opposite diagonal of the arena, with the trajectory of its center specified by the following parametric equations:

$$x_{1o}(t) = 2.875 - 0.1375t, \ x_{2o}(t) = 0.125 + 0.1375t, \ x_{3o}(t) = -0.1t^2 + 2t + 0.125.$$

Here, we consider the template for the STTs as second-order polynomials in time t: $p_{i,l}(t) = \{1, t, t^2\}$, for $l = \{L, U\}$. The STT obtained to solve the T-RAS task for this case is given by the following curves:

$$\begin{split} \gamma_{1,L}(c_{1,L},t) &= 2.75 - 0.0296t - 0.0054t^2, \\ \gamma_{1,U}(c_{1,U},t) &= 3 - 0.0396t - 0.0049t^2, \\ \gamma_{2,L}(c_{2,L},t) &= 2.75 - 0.1336t - 0.0002t^2, \\ \gamma_{2,U}(c_{2,U},t) &= 3 - 0.1436t + 0.0003t^2, \\ \gamma_{3,L}(c_{3,L},t) &= 0 + 1.9175t - 0.0959t^2, \\ \gamma_{3,U}(c_{3,U},t) &= 0.25 + 1.9075t - 0.0954t^2. \end{split}$$

The trajectory of the drones under the influence of the proposed control law in (10), as well as the obtained samplingbased STTs for the drone in each dimension is shown in Figure 4.

All the computations were performed on a machine with a Linux Ubuntu operating system with Intel i7-7700 CPU and 32GB RAM.

Discussion and Comparison: The efficacy of our approach is demonstrated across various systems and settings. While the omnidirectional robot and manipulator case studies show safe navigation in a two-dimensional environment with multiple complex-shaped unsafe sets, the magnetic levitator system demonstrates the approach's success in managing timed unsafe sets. Finally, drone navigation illustrates its scalability for systems in the presence of time-varying unsafe sets. Furthermore, real-world testing Videos validates the real-time practical applicability of the STT approach.

Figure 4: Trajectory of drone with static and dynamic obstacles in a 3D environment (left) and respective STTs (right)

It is also important to note that, the generation of STTs occurs offline, with only the closed-form control law, which is highly computationally efficient, applied in real-time. This design choice significantly enhances scalability, making it suitable for high-dimensional systems and environments with complex safety constraints.

<u>Comparison</u>: Path planning algorithms [51] offer a potential solution to the case studies, albeit with moderate to high computational complexity and lacking formal guarantees of solution. Conversely, symbolic control techniques [4,47] promise formal guarantees but come at the expense of increased computational complexity and demanding the knowledge of exact mathematical models. Although it takes moderate time to generate a STT, the sampling-based approach gives a formal guarantee under unknown dynamics to satisfy the T-RAS task. The comparison of different aspects of the proposed STTs with state-of-the-art algorithms is shown in Table 1. Note that it is difficult to handle time-dependent obstacles using state-of-art algorithms. In contrast, STTs can handle them, as shown in the case of the magnetic levitator system.

6 Conclusion and Future Work

The paper focuses on constructing the STTs using a sampling-based approach from the available data of temporal unsafe sets, aiming to ensure the temporal reach-avoid-stay (T-RAS) task. We formulate an SOP to assemble obstacle data and model the tube so that it ensures the T-RAS task is completed with a certified confidence of 1. Consequently, we can design a closed-form, approximation-free control law to retain the unknown MIMO pure-feedback system's trajectory within the tube. We showcase the success of our approach through three different case studies.

Although the case studies significantly support the proposed approach, the time complexity of constructing the tube for any general case is subject to further investigation as it depends on the length of time horizon, the volume of unsafe region, and the degree of the tube polynomial, hence being tedious to calculate. The proposed approach cannot consider arbitrary input constraints; in future work, we also aim to develop solutions accommodating input constraints. Finally in this work, we focused on fully actuated systems, and in future work, we plan to extend our approach to general underactuated nonlinear systems.

Appendix A. Computation of Lipschitz constants \mathcal{L}_L and \mathcal{L}_U

Employing the results of [52], we propose the Algorithm 1 to estimate the Lipschitz constants of the STTs using a finite number of data collected from the tube boundary. Though we introduce the algorithm for the computation of \mathcal{L}_L , one can leverage a similar algorithm to estimate \mathcal{L}_U , following the same procedure.

Algorithm 1 Estimation of \mathcal{L}_L using data

- 1: Select two time instances randomly t_j, t_k such that $||t_j t_k|| \le \alpha, \forall j, k \in [1; \overline{N}], \alpha \in \mathbb{R}_{>0}$
- 2: Calculate $\theta_j^i = \gamma_{i,L}(c_{i,L}, t_j)$ and $\theta_k^i = \gamma_{i,L}(c_{i,L}, t_k)$ where θ_j^i and θ_k^i denotes the lower bound of the tube in *i*-th dimension at *j*-th and *k*-th time instances
- 3: Compute slope $S_{jk}^i = \frac{\|\theta_j^i \theta_k^i\|}{t_j t_k}, \quad \forall j \neq k$
- 4: Compute maximum slope as $\Psi_i = \max\{S_{ik}^i | j, k \in [1; \overline{N}], j \neq k\}$
- 5: Repeat steps 1-4 M times and obtain $\Psi_{i,1}, \ldots, \Psi_{i,M}$
- 6: Apply Reverse Weibull Distribution [52] to $\Psi_{i,1}, \ldots, \Psi_{i,M}$, which gives us so-called location, scale and shape parameters
- 7: The obtained *location parameter* is denoted by \mathcal{L}_i
- 8: Repeat steps 1-7 to get $\mathcal{L}_1, \ldots, \mathcal{L}_n$
- 9: $\mathcal{L}_L = \max\{\mathcal{L}_1, \ldots, \mathcal{L}_n\}$

The following Lemma 6.1, borrowed from [52], under the proposed algorithm ensures the convergence of the estimated Lipschitz constants to their actual values.

Lemma 6.1 ([37]) In the verge of Algorithm 1, the estimated Lipschitz constants \mathcal{L}_L and \mathcal{L}_U tends to their actual values if and only if α goes to zero with \overline{N} , M tends to infinity.

Note that, picking minimal value of α and very high value of \overline{N} , M will give a precise approximation of the Lipschitz constants.
