## ABSTRACT

Construction robotics has gained significant traction in research and development, yet deploying robots in construction environments presents unique challenges. Construction sites are characterized by dynamic conditions, domain-specific tasks, and complex navigation requirements that make traditional robot pathfinding approaches insufficient. While methods like simultaneous localization and mapping (SLAM) offer viable solutions for robot navigation, they often require considerable computational resources due to their sensor precision demands and data processing needs. This paper presents a novel approach that leverages building information modeling (BIM) for efficient, domain-specific pathfinding by utilizing both spatial and semantic information. We integrate a multi-heuristic A\* (MHA\*) algorithm with artificial potential fields (APF) derived from BIM spatial data, while employing large language models (LLMs) to process BIM's textual information for dynamic obstacle avoidance. Our experimental results demonstrate an 80% improvement in robot-obstacle clearance while maintaining comparable path lengths to traditional methods. This approach provides a computationally efficient solution for safe robot navigation in complex construction environments.

**INDEX TERMS** robotics, A\*, APF, pathfinding, construction, NLP, LLM

## I. INTRODUCTION

Robotic pathfinding has been an active area of research since the 1960s. Pathfinding deals with the problem of how to move a robot from one point to another. Many algorithms have been developed to tackle autonomous agents' pathfinding and guidance for known and unknown environments [34]. In known environments, approaches such as artificial potential fields (APF) generate attractive and repulsive potential forces that guide the agent through the global environment [44]. Other approaches including heuristic search and graph search algorithms (e.g., A\* and Dijkstra) aim to find the shortest path from the start goal to the end goal [28] [29]. However, in some scenarios, the shortest path is not the most optimal path. This is particularly the case in the construction industry domain. Given the dynamic nature of the construction sites, collisions can occur when rapid environmental changes transform a known environment into an unknown one. Therefore, It is extremely important to plan for this dynamism using object avoidance approaches both in real-time and in the mission

planning stage.

Real-time collision avoidance methods have been developed using visual information [1] and LiDAR-based approaches [46]. However, these methods can increase the computational and power costs of the agent. Building information modeling (BIM), which results in a digital 3D representation of a facility's physical and functional characteristics, provides a rich source of spatio-temporal and semantic information that can be leveraged with very low computational cost. BIM has shown significant promise in the field of construction robotics. For example, BIM proved beneficial in simultaneous localization and mapping (SLAM) in construction research where researchers address building progress monitoring using robots and mapping techniques [6]. Additionally, the presence of textual information embedded in BIM 3D models allows leveraging natural language processing (NLP) for explainability, thus improving the pathfinding process. Through the use of large language models (LLMs), natural language has been successfully used as a tool for robotic

guidance as well [13]. Natural language not only helps with enhancing human-robot interaction and semantic understanding of the environment and task objectives, but it also enables explainability, a pivotal feature for the widespread integration of robots in human-centered industrial settings that has been shown to have a significant impact on robot trustworthiness in construction [19] [39]. In this paper, we propose to use the textual BIM family properties to detect the uncertainty of accurate mapping from the semantic information in the BIM models and use it to scale and generate the APFs depending on the objects' risks dynamically. Additionally, we generate explanations on decisions made by the algorithm to enhance trust and communications. The values from the APFs are then formulated into heuristics to be used with an admissible heuristic such as Euclidean distance, which results in a safe and aware pathfinding.

## II. LITERATURE REVIEW

### A. BIM LOCALIZATION

BIM serves as a comprehensive source of data for learning-based methods such as machine learning (ML) algorithms [54]. The robust and diverse semantic information embedded in BIM models can assist in developing new ML models for more efficient, safer, and more sustainable construction processes. That is why BIM has been leveraged in important robotics applications [57], aiding in such tasks as localization and mapping [30] and pathfinding [58]. However, due to the discrepancies between as-designed and as-built models (that is the difference between what is modeled and what is built in the field), relying only on BIM or A\* (without using methods such as APF) can result in collisions in real-time deployments. Recent studies have managed to achieve a localization error of 20cm [53] which is not considered safe around humans and in jobsite environments.

Indoor localization of workers is a well-researched topic [27]. Previous works have been able to calibrate and match objects between objects and virtual environments [38]. Methods such as passive radio frequency identification (RFID) and wireless [9], [11], visual and inertial sensors [52] and monocular cameras [15] have shown advancements in the localization of objects and workers in a BIM world. However, all of these measurements have innate errors which can impose risks in mobile robot path planning. To use BIM models for robot path planning, these discrepancies and errors need to be accounted for to ensure safe human-robot collaboration and risk mitigation.

### B. A\* SEARCH

A\* search algorithm is a graph traversal and pathfinding algorithm that is used in robotics and computer science [35]. Outside of the field of robotics, many other fields also use the A\* algorithm to solve their graph traversal problems. In video games, A\* is an extremely popular algorithm for agent pathfinding [59]. Many game engines such as Unity have their own in-built A\* implementation for developers to use. The algorithm uses weighted graphs to find the shortest

path between the start node and the goal node, and a heuristic function calculates the cost of each node. As long as it is admissible, meaning it never overestimates the cost, the algorithm is guaranteed to generate the shortest path with efficient computational requirements. This is incredibly useful in known environments, and many current studies focus on representing real-world environments in a virtual setting using digital twins for path planning [22] [47] [8]. Recent advancements in digital twins have increased the match between the virtual and the real world, but certain discrepancies are inevitable. Since the original A\* algorithm assumes the environment is fully known, these discrepancies can introduce risks to the system. With the introduction of the A\* algorithm, a multitude of new variations to improve pathfinding and computational efficiency have emerged. However, one of A\*'s biggest drawbacks is the worst-case memory and runtime needs that grow exponentially with respect to the depth of the search [18]. Many alternatives have been developed such as the weighted A\* [18], anytime A\* variants [26], and multi-resolution variants [17].

### C. ARTIFICIAL POTENTIAL FIELDS

APF is a well-established path-finding method used in robotics [45]. The main idea of APFs is to generate a potential field with a combination of attractive and repulsive forces. Obstacles generate repulsive behavior and the goal will be represented as an attractive force that pulls the agent towards itself. APFs have proven very useful in robot path planning. However, some inherent issues such as (1) the absence of a feasible path in dense obstacle spaces; (2) the path trajectory goes beyond the equilibrium position, oscillating, or repeatedly closed-loop in the narrow space; and (3) it is trapped in the local minima before reaching the target, introduce functional drawbacks to real-world applications [49]. Previously, APF has been used with rapid tree search algorithms [48]. Given that BIM and digital twins have detailed 3D representations, APF is a promising candidate to be incorporated with BIM for planning. Hence, we propose to use the APF as a potentially inadmissible heuristic given by the rich but naturally error-prone spatial data of BIM. Previous studies have investigated the use of A\* and APF together for local and global path planning for multiple surface vehicle formations [36]. For example, Zhang et al. have used APFs with A\* improved AGV pathfinding [56]. However, a major limitation of those works is that the potential value of the cost function is incorporated linearly, formulating a new heuristic function. The APF is not necessarily an admissible heuristic and the admissibility of a new heuristic was not addressed in that work either. That is why we propose to use the multi-heuristic A\* (MHA\*) that can use multiple inadmissible heuristics (in this case the potential values from the APF), and a consistent and admissible heuristic (Euclidean distance) to provide optimality and completeness that is necessary for A\*'s success [3].

#### D. TRUST AND REASONING CAPABILITIES IN LLMs

Lack of transparency in construction robotics has been identified as one of the main barriers to the widespread adoption of industrial and collaborative robots [20]. Many previous works have identified that robot communication through natural language can increase trust between the human and the artificial agent [51] [7]. LLMs have shown advanced capabilities in logical deduction and reasoning [12]. Furthermore, LLMs have been able to utilize multi-modal architectures to be able to extend their reasoning capabilities to multiple modalities such as images and videos creating Visual Language Models (VLM) [4]. Additionally, LLMs have been used as agents for hazard analysis for safety-critical systems due to their strong reasoning capabilities [16]. LLMs have also been used effectively in the construction industry for tasks such as reporting and generating construction progress reports [33]. Other construction-related tasks such as compliance [10] and architectural detailing have also effectively benefited from LLMs [24]. Leveraging previously known information to create informed ML models has shown significant promise in creating informed machine learning systems [43]. By introducing prior knowledge explicitly in the model independent from the training data, ML algorithms have been shown to perform more effectively. Previous works have shown that NLP can be integrated in a similar fashion with unrelated learning algorithms to improve their performance [25]. The authors have previously explored semantic informed ML in the context of human activity recognition in the construction industry [5]. Given the above mentioned literature and proven potential, in this work we use LLMs for scaling and weighing the localization errors of the BIM families to strike a balance between object avoidance and path length. This is while the presented framework allows for transparent communication of the reason behind using certain scalings to enhance the pathfinding process, as well as having natural language communication ability to reason about mission planning.

#### III. METHODOLOGY

This section outlines the building blocks of the proposed methodology, where APF and A\* algorithms are fused to determine safe navigation paths. This is enabled by converting higher dimensional BIM models into graph-based, 2D floorplans, as described below.

##### A. GRAPH GENERATION

We propose a multi-heuristic A\* (MHA\*) algorithm to formulate a global path-finding process. Since A\* is a graph traversal algorithm, the first step in the framework would be to generate a 2D grid representing the floor plan and walkable regions of the environment.

We use Python in conjunction with Unity Game Engine, which is a popular tool in the literature for robotics and BIM-based positioning studies due to its intuitive and visual 3D representations and ROS# package [14] [40] [23]. It is important to note that the proposed framework does not require using a game engine as a necessary component, and it is

leveraged here as a simulation and visualization tool only. Unity provides a navigation mesh function called NavMesh that saves the scene's geometry as convex polygons [42], which has been tested previously in construction robotic path-planning studies [22] with successful results. The function can detect walkable and un-walkable areas with high flexibility and uses the edges of the detected polygons to connect the traversable areas. An example of the NavMesh graph can be seen in Figure 1

FIGURE 1. Graph Generation using Unity's Navigation Package

Since the NavMesh function represents the geometry as convex polygons, typical graph traversal algorithms such as A\* will calculate the shortest distance between the destination and the agent. This would result in the agent following along the edges of the polygons since the shortest distance would naturally cost less.

To incorporate APFs for object-safe path planning, we need to be able to project the potential values across the environment. Even though having the NavMesh representation decreases computational costs while maintaining high functionality, we need to deviate from only using the edges of the polygons in our cost functions to incorporate APF into the system. We use the geometry of the floor to generate a "Moore's Neighborhood"-a grid similar to what is shown in Figure 2.

**FIGURE 2.** Moore's Neighborhood Graph

**FIGURE 3.** Generated Grid in Unity with the Moore's Neighborhood Node Connections

A Moore's Neighborhood grid, as depicted in Figure 2, is a 2-dimensional grid that grants 8 degrees of freedom to the agent. We chose this setup to avoid a "lawnmower" movement from the agent by connecting each node to all of its immediate neighbors [55].

Depending on the geometry and node sizes, this setup creates significantly more nodal connections than Unity's NavMesh (see Figure 3). While this setup provides more granular and fine movements, it also increases the computational complexity of the mission. However, this is not a concern here since the frame rates and performance of the Unity client are not of significant importance in the proposed application compared to video-game settings. This situation increases the viability of developing alternative methodologies as opposed to the in-built NavMesh function for functional purposes. The determination of walkable and unwalkable nodes are detected by the intersection of the grid objects with the walkable area of the NavMesh itself.

### B. ATTRACTIVE POTENTIAL

The attractive potential is calculated using the equation:

$$U_{att}(x, y) = \frac{1}{2} k_{att} \cdot D_{goal} \quad (1)$$

where  $D_{goal}$  computes the distance between any grid point  $(x, y)$  and the goal and  $k_{att}$  is the attractive coefficient. The farther we are from the goal, the stronger the potential field which facilitates more aggressive and direct path planning. Different scaling factors can be used to tune the function depending on applications and environments. The distance can be calculated with different measurement approaches. In this paper, we examine the Euclidean distance:

$$D_{Euclidian} = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2} \quad (2)$$

where  $x$  and  $y$  are the coordinates of the start and end nodes.

### C. REPULSIVE POTENTIAL

The repulsive potential around obstacles is given by an exponential decay function:

$$F_{rep}(x, y) = k_{rep} \cdot e^{-D_{obstacle}} \quad (3)$$

where  $D$  measures the distance to the nearest obstacle point,  $k_{rep}$  is the repulsive coefficient. Exponential decay functions have been used in previous works to create more smooth potentials [32]. This will allow to create walkable regions in the floor plan generated from the BIM model.

### D. MHA\* SEARCH

We utilize a MHA\* graph traversal algorithm for our pathfinding problem. MHA\* guarantees completeness and optimality even though the APF heuristic is potentially inadmissible. This is an advance from previous works that do not account for the admissibility of the APF. The proof for completeness and optimality can be further found in the original paper [3]. Our admissible heuristic is given by the Euclidean distance in Equation 2. Our potentially inadmissible heuristic that is used for object avoidance is the summation of all the magnitude of the forces on each node minus the attractive force on the node:

$$F_{total} = \sum_{i=1}^n k_i F_{r_i} - F_a \quad (4)$$

APF and Euclidean distance are now used as our two heuristic functions for object-aware pathfinding. Each one of these heuristics will have its open set that will be chosen for state expansion in the search.

We also use a Gaussian blurring function that is convoluted with the potential field to get a smooth representation of the original potential field, which is a technique commonly used in 2D image processing [21]:

$$G(x, y) = \frac{1}{2\pi\sigma^2} e^{-\frac{x^2+y^2}{2\sigma^2}} \quad (5)$$

Results of applying a convolution process over the Gaussian kernel can be seen in Figures 4 and 5. In these figures, the floorplan depicted in Figure 3 is transformed into a potential field emitted by the objects. A high potential value is represented in the red color with a maximum value of 3500, and the low potential values are represented with the blue color with the minimum of zero. The smoothing gives a more natural

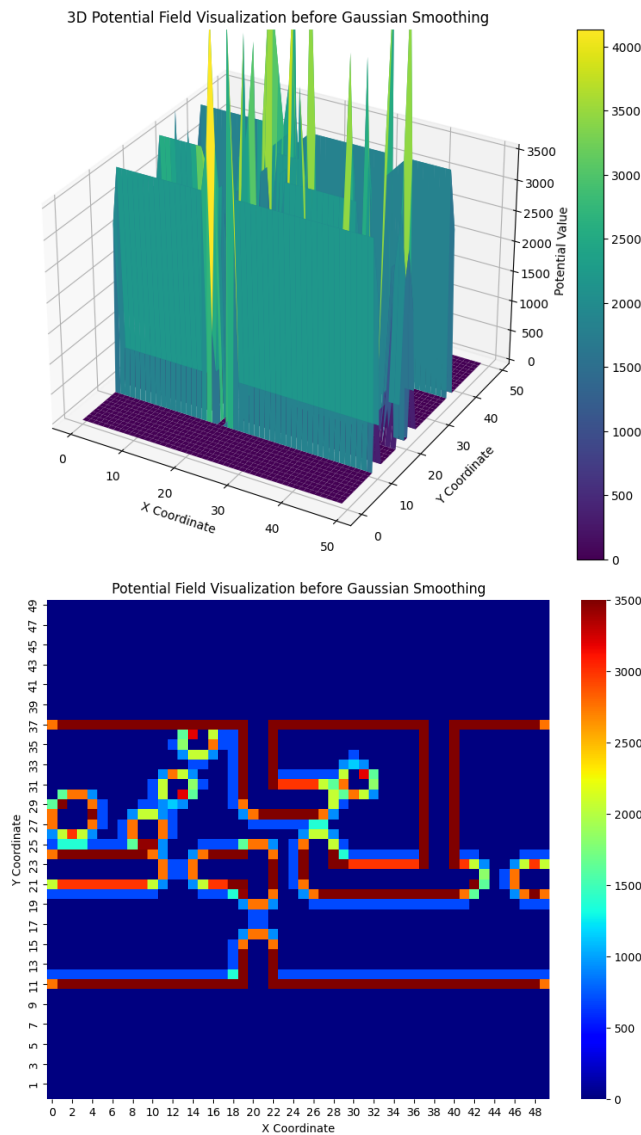

FIGURE 4. Potential field before Gaussian Smoothing

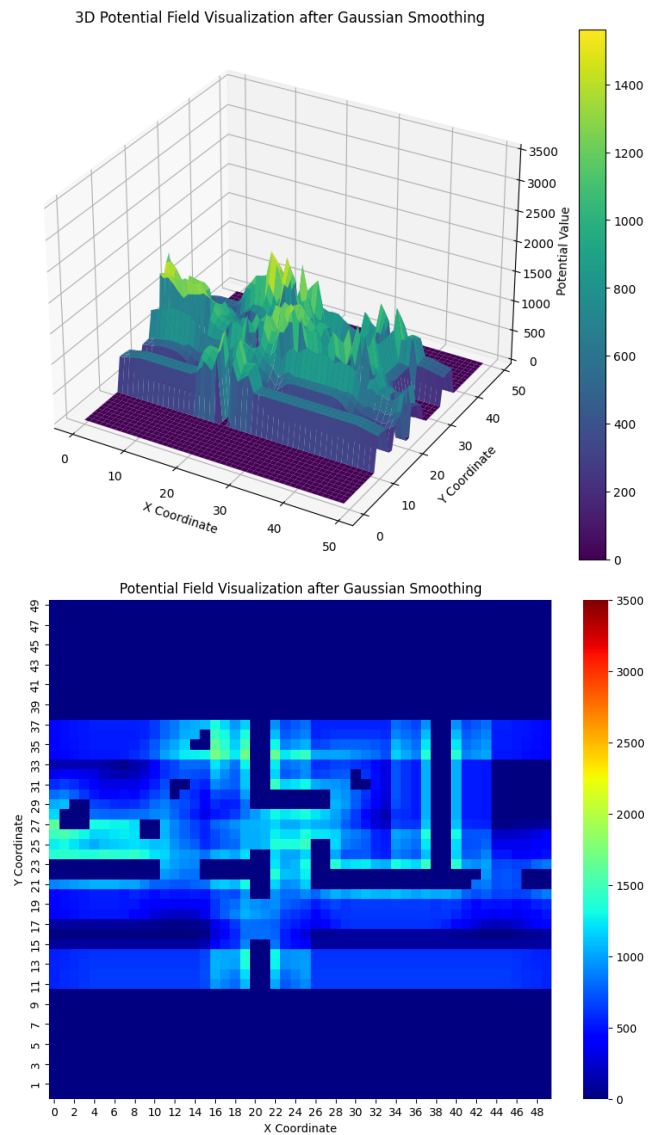

FIGURE 5. Potential Field after Gaussian Smoothing

distribution of the potentials to further assist the algorithm in incorporating the potential better.

Moreover, the Gaussian blur further stretches the effects of the potential field, acting as a second extension of the exponential function formulated in Equation 3 to smooth out the initial function over the domain. The difference between not using and using the smoothing in pathfinding performance can be seen in Figures 8 and 9.

### E. LLM

Construction job processes have nuanced and esoteric nomenclature. Different companies and projects could use different terms for similar activities. This variation can cause errors and malfunctions in traditional NLP approaches. Previously, NLP was limited to regular expressions and keyword searching. With the rise of LLMs, NLP has the opportunity to use reason-

ing and context to better process prompts. In this setting, we introduce the integration of LLMs to be able to analyze BIM families names (i.e., a collection of elements with identical use, common parameters, and similar geometry) and other textual information. Given the dynamic nature of jobsites, certain objects can be moved or misplaced more frequently than others. Furthermore, certain localization errors can be communicated to the framework via the context prompt of the GPT. These flexibilities make an LLM integration an attractive extension to traditional construction robot mission planning.

The framework script prompts the GPT using JSON files to supply the model with information. A list is created with every single family and object instance of the BIM file. The GPT is then prompted with instructions to identify danger levels given the description of each family. Then, these coefficients

FIGURE 6. Framework of integrating LLM's into the A\* Algorithm

FIGURE 7. Naive A\* Pathfinding. (Yellow: Chair, Blue: Robot, Gray: Grinder)

are applied to the A\* algorithm. Different steps of the framework are shown in Figure 6.

#### IV. EXPERIMENTS AND VALIDATION

We used a BIM model of an existing suite of rooms at SDSU (with its 2D plan appeared in the Figures 3-12) to validate the pathfinding algorithm. Initially, an (i.e., a geometry preserving file format used for interoperability) was exported from an RVT (i.e., Revit file) to generate a 3D representation of the space. To use it in Unity, we simply imported the FBX file and use the floor as the geometry for navigation. For the Python implementation, we generated a cross-section of the 3D file to generate a 2D map of the floor. In the following subsections, we delineate the differences between the output of MHA\* (A\* with APF) versus A\* classic, and then expand on the BIM-LLM integration for the algorithm.

##### 1) MHA\* vs classic A\*

The output of any A\* algorithm would be a list of node coordinates which are the immediate neighbors of the prior node. The metric that we used to evaluate the overall object avoidance of each algorithm is the average of the distance of each node from the closest un-walkable node (in this case the nodes are rendered un-walkable if they appear on an object) and the total count of the nodes needed to complete the path. We experimented with 1) a naive A\* which only accounts for distance in its calculations, 2) MHA\* without Gaussian smoothing, and 3) MHA\* approach with Gaussian smoothing. Figure 7 shows the naive A\* path, Figure 8 shows the MHA\* without Gaussian smoothing, and Figure 9 shows the path for the MHA\* algorithm after Gaussian smoothing.

As it is shown in Table 1, with the MHA\* method, the agent can reach the destination with the same path length of the naive algorithm. However, the method results in about 75% increase in Average Distance to Obstacle (ADO) than the

FIGURE 8. MHA\* without Gaussian Smoothing

FIGURE 9. MHA\* with Gaussian Smoothing

naive algorithm. This is a significant improvement in mission planning safety. Also, the effects of smoothing in reducing the path length while generating a smaller average distance to obstacles are noteworthy.

In these scenarios, we gave the potential field a scaling factor of 0.5. The idea behind the scaling factor is to create a mechanism to be able to adjust the potential field generated from each object to affect the behavior of the path. However, this is not optimal since different objects can have similar perceived danger levels without considering their geometry, unpredictable movement, and cost. While the user can manually assign these values in the software, the textual data depending on the size of the BIM can become cumbersome, and near real-time changes to values depending on the environment and scenario can be unfeasible. Furthermore, given different nomenclatures regarding how to name BIM families depending on the organization, a direct scaling method is not effective. To address this, we propose to use LLMs to use the textual information embedded in the BIM model to dynamically weigh and scale the potential force emitted from the BIM families.

##### 2) LLM Integration

To further integrate explainability and adaptability, we propose to use LLM as a reasoning agent to identify and detect danger levels. By using the names and descriptions of the families of the BIM model, the GPT can generate danger coefficients using prompts. The GPT can be used to generate either potential strength coefficients or cost scaling coefficients, or

Algorithm	Path Length	ADO
Naive A*	4.29	0.34
MHA* without Gaussian Smoothing	4.55	0.50
MHA* with Gaussian Smoothing	4.29	0.58

**TABLE 1.** Comparison of Naive A\* and A\*-APF Fusion algorithms with path length and Average Distance to Obstacle (ADO)

both in different implementations. In our framework, we use the GPT to generate scaling values between 0 to 1.

To integrate the LLM with the Unity game engine, we use the OpenAI GPT API. The model used was the GPT 3.5 turbo [50]. GPT 3.5-turbo was chosen due to its speed and efficacy. While other LLMs such as GPT-4 [31] or Gemini [41] could be used as well, they would require more resources and processing times due to their more complex architecture. Most modern GPTs such as GPT 4o and o1 have orders of magnitude more parameters than the GPT 3.5-turbo. This increase in model size will increase cost and computational times, which can be problematic in practical applications. Depending on the number of families used in the BIM model, the scalar addition of the coefficients can exceed 1, which would cause the algorithm to fail. To counteract that, all the APF cost coefficients are scaled and normalized to a maximum of 0.5 for when all are added to each other.

The framework also has an explanation section that communicates why each coefficient has been chosen to be able to better tune the model and have a transparent and safe operation. A formatted version of the GPT output in our test case is as follows:

#### Object Evaluation and Danger Coefficients:

- **Basic Wall Interior Partition (x12):**
  - Danger Level: 0.2
  - Reasoning: Static objects, easily navigated around. Low danger level.
- **Chair:**
  - Danger Level: 0.5
  - Reasoning: Potential obstruction, moderate risk.
- **Other Robot:**
  - Danger Level: 0.8
  - Reasoning: Dynamic object with unpredictable movements. Higher risk.
- **Grinder:**
  - Danger Level: 0.9
  - Reasoning: High-risk due to cutting capabilities and potential for serious harm. Highest danger level.

We can see transparent and valid reasoning for the danger levels of each object. After this text is returned, we use regular expressions (Regex) techniques [2] to parse the specific coefficients. These coefficients are then normalized and applied to the BIM families, preparing the potential fields for path planning. To evaluate this method we use two separate scenario initializations.

### A. SCENARIO 1

We test the BIM layout from the previous experiments to compare LLM integration and the variants without sentiment analysis directly. The results can be seen in Figure 10 and Table 2. As it can be seen, the GPT weighing increases the average distance to approximately 0.63 meters which is about 80% higher than the naive A\* method. Figure 10 and Table 2 show the difference between the paths given the presence of the "chair" and the "walls" near the path and considering their relative danger level.

**FIGURE 10.** GPT-MHA\* using GPT-3.5-turbo for Scaling Values Depending on the Semantic Evaluation of Danger Levels of the BIM Families

Algorithm	Path Length	ADO
GPT-MHA*	4.61	0.63
Naive A*	4.29	0.34

**TABLE 2.** Results for the A\*-APF Algorithm Integrated with GPT-3.5

### B. SCENARIO 2

In this scenario, we place the objects close to the entrance of the nearest entry point to the room of interest. Given this setup, the safer route would be to enter the room above to enter through a side door as opposed to entering through the door with clustered obstacles. Figure 11 gives the closest path given by A\*. The naive A\* will take the shortest path possible. However, the MHA\* approach should avoid the cluster of nearby objects due to the repulsive heuristic.

Figure 12 shows the path given by the proposed MHA\* method. Table 3 contains the statistics regarding the performance of the two different algorithms. We can see that the GPT-MHA\* takes a longer path while maintaining a larger distance to obstacles on average as opposed to the naive A\*.

Algorithm	Path Length	ADO
GPT-MHA*	5.35	0.28
Naive A*	3.4	0.2

**TABLE 3.** Scenario 2 Path Statistics

## V. DISCUSSION

Path planning by leveraging digital twins has great potential for indoor environments. With the assumption that near real-time representation of the work environment is reflected in

FIGURE 11. A\* Path in Scenario 2

FIGURE 12. MHA\* Path in Scenario 2

the BIM world, this is even a more promising mechanism. As discussed earlier and shown in the literature, different environmental sensors such as RFID and camera sensors can prove to be object avoidance and mapping tools for the robot. However, with a better twinning of the locations of obstacles in a building environment, mission planning will be more likely to avoid collisions due to a more representative understanding of the environment. This advantage can further reduce the load from sensors used on the robot for object collision. This expenditure reduction can benefit other process performance, battery life, and implementation costs.

The developed framework grants significant flexibility to users. Sensitive, high-value, or hazardous objects can each have their own specific potential strength and scaling factors. Certain rooms can be assigned with certain potential strengths and scaling factors to balance between the shortest distance and object avoidance even given the schedule and conditions of the environment. The balance between object avoidance and the shortest path needs to be determined by the use case of the robot's mission since higher weights for object avoidance can cause longer paths

If the environment is unchanged, the A\* algorithm executes once and a global path is acquired. This saves computational resources instead of calculating the path once and then using local path planning for better object avoidance. However, if the environment changes, the global path needs to be recalculated at every instance. Regardless, this is not detrimental

to the robot since the computations are offloaded to a host computer. The simulation sends the robot move commands through ROS or any other API the users use. This protocol reduces the edge computing requirements of the robot and improves the latency of other functionalities that the robot needs to conduct.

## VI. CONCLUSION AND FUTURE WORK

In conclusion, this work proposes a new path-planning technique that combines A\* and APF using MHA\* which is then further incorporated with an LLM for explainability and adaptability. We create a pipeline to use BIM spatial and semantic information to aid our path-planning logic with the aim of collision avoidance. While this method does not replace real-time object avoidance techniques, it creates an additional safety consideration in the planning phase for the robot before the mission starts. We can use the semantic and textual information from BIM using LLMs and incorporate them with classical AI algorithms. The GPT semantic analysis presented here can also provide transparency in the robot's decision-making, a crucial facet in the application of robots in the AEC industry.

The proposed work focuses on implementing this navigation strategy in 2D for ground robots. This framework can be extended to 3D by incorporating the height axis into the heuristic calculation and grid generation. The grid will have a voxel representation with a repulsive and distance heuristic for each voxel. To ensure accurate potential calculation, accurate mesh representation of the objects is highly important.

For future work, we plan to create dynamic scalar adjustments depending on both semantic and environmental changes. We plan to incorporate online object avoidance techniques such as SLAM processes to create a more holistic framework. In this research, we did not explore the effects of the efficiency and convergence speed of the algorithm. Multi-resolution approaches have shown to be effective in reducing the computational needs of the A\* algorithm by dynamically adjusting the search resolution of the algorithm. AMRA\* is an anytime, multi-resolution, and multi-heuristic A\* algorithm that can handle multiple heuristics and multiple resolutions which we plan to implement in the future [37].

**MANI AMANI** received the B.S. in Cognitive Science from the University of California, San Diego. He is currently a Ph.D student at San Diego State University and University of California, San Diego.

**REZA AKHAVIAN** received a B.S. (2010) in Civil Engineering from the University of Tehran, and a M.S. (2012) and a Ph.D. (2015) in Civil Engineering from the University of Central Florida. He is currently an Associate Professor at the Department of Civil, Construction, and Environmental Engineering, and the director of the Data-informed Construction Engineering (DiCE) research lab at San Diego State University. Dr. Akhavian has received several honors and awards including the NSF CAREER Award. His research focuses on advancing the theories and adoption of technologies such as robotics, artificial intelligence (AI), internet-of-things (IoT), cyber-physical systems (CPS), and augmented and virtual reality (AR/VR) in engineering and construction domains. He is the elected Secretary of the American Society of Civil Engineers (ASCE) Visualization, Information Modeling and Simulation (VIMS) Committee, and serves on the editorial board of the ASCE Journal of Construction Engineering and Management and Elsevier Advanced Engineering Informatics.
