Abstract-Reconfigurable Intelligent Surfaces (RISs) are envisioned to be employed in next generation wireless networks to enhance the communication and radio localization services. In this paper, we propose novel localization and tracking algorithms exploiting reflections through RISs at multiple receivers. We utilize a single antenna transmitter (Tx) and multiple single antenna receivers (Rxs) to estimate the position and the velocity of users (e.g. vehicles) equipped with RISs. Then, we design the RIS phase shifts to separate the signals from different users. The proposed algorithms exploit the geometry information of the signal at the RISs to localize and track the users. We also conduct a comprehensive analysis of the Cramer-Rao lower bound (CRLB) of the localization system. Compared to the time of arrival (ToA)-based localization approach, the proposed method reduces the localization error by a factor up to three. Also, the simulation results show the accuracy of the proposed tracking approach.

Index Terms—Reconfigurable Intelligent Surface, Tracking, Localization, Cramer-Rao Lower Bound

I. INTRODUCTION

W ITH the progress of technology over the last decades, localization and tracking have become one of the necessities in human life. Applications of localization are in navigation of vehicles and robots, emergency services, location-based services in wireless networks, security, etc. Due to the inherent limitations of Global Positioning System (GPS) in indoor environments and outdoor environments with tall buildings, the attention of the researchers has been turned to the radio localization, motivating a huge interest in the integration of localization, sensing and communication (ISAC) in future wireless systems [1]-[5]. The main challenge of radio localization systems is to simultaneously achieve wide coverage and high accuracy, while using the minimum number of transmitters (Txs)/receivers (Rxs) [6], [7]. A promising technology to help overcome this challenge is Reconfigurable Intelligent Surface (RIS).

An RIS is a planner array composed of passive reflecting elements with dynamically configurable phase shifts. RISs

In many of the localization researches the RISs are considered as anchor nodes with known location. The deployment of RISs to improve the accuracy is one of the initial problems explored in this context. In this regard, enhancing the localization accuracy in a system equipped by a single antenna Tx/Rx and multi-antenna Rx/Tx has been examined in [14]-[17]. Also, in [18]-[20], this problem is investigated in a system equipped with multi-antenna Tx and Rx. Moreover, the authors in [21]-[24] investigated the problem of localizing a single antenna user equipment (UE) employing a single antenna Tx. Another challenge is employing RISs to localize the UEs without any access point [25], [26]. Also, the problem of localizing unknown location Txs and Rxs has been investigated in [27], [28]. The enhancement of the tracking accuracy is another role for the RISs, which is studied in [29], [30].

However, all of these works assume that the location of the RIS is known and use it as anchor. But, what if the RISs are deployed on vehicles and we are uncertain about their precise location? In such situations, we need to estimate the location of the RIS itself. There are a limited number of studies that address the RIS localization problem [31]-[35]. In [31], localization of RIS-equipped UEs using a Tx and multiple Rxs is considered, where, for each RIS the time difference of arrival (TDoA) of the path including the RIS and each Rx and the direct path between the Tx and Rx is measured and the location of the RIS is estimated by minimizing the maximum likelihood (ML) for the TDoAs. Thus, at least three Rxs are required to localize the RISs in this work. In [32], the problem of localizing an RIS in the near field is investigated. In this article, a ML estimation problem is defined to localize the RIS using one Tx and one Rx. In [33]-[35], a multipleinput multiple-output (MIMO) Rx is employed to estimate the location of the RIS and the Tx (user). To do this, in [33] a prior information about the locations is utilized, while in [34], [35] active and hybrid RISs are employed, respectively.

However, these works mostly consider static scenarios which is not suitable for mobile RIS such as vehicles equipped with RIS in smart transportation systems where the mobility features such as Doppler effect can not be ignored. To the best of our knowledge, this paper is the first study of the RIS tracking problem.

In this paper, we study the problem of tracking the trajectory and speed of multiple UEs (e.g., vehicles) each equipped with an RIS, in the presence of the scatters, employing a single

antenna Tx and multiple single antenna Rxs. In this regard, first we propose a novel localization algorithm to estimate the initial location of the RISs. Then, we propose an efficient algorithm for simultaneous tracking of multiple RISs. Table I summarizes the key differences between this work and the literature. The contributions of this paper are summarized as follows.

- We propose an algorithm to simultaneously track the trajectory and speed of multiple RISs based on extended Kalman filtering (EKF). The proposed approach leverages the time of arrival (ToA) of the paths and information about the geometry of the reflected signals at the RIS.
- By estimating the ToAs and sum cosines of the angle of arrival (AoA) and angle of departure (AoD) at each RIS as the measurement parameters, we also propose an RIS localization algorithm to initialize the tracking. To do so, we design the phase shifts to extract the signals reflected by various RISs and discriminate them from those reflected by scatterers at each Rx. Thanks to the exploited geometric information, the proposed localization approach works even with a single Rx.
- We derive the Cramer-Rao lower bound (CRLB) and demonstrate the behaviour of Position Error Bound (PEB) in terms of the distance between the RIS and the line between the Tx and Rx.

The rest of the paper is organized as follows. In Section II, we present the system model. In Section III, the phase shifts design approach, measurement parameters and the proposed localization approach are introduced. Section IV provides the proposed tracking approach. The CRLB of the localization system is derived in Section V. Section VI presents the simulation results, and Section VII concludes the paper.

Notations. The vectors and the matrices are denoted with boldface letters and boldface capital letters, respectively. For matrix **A**, tr{**A**} denotes the trace of the matrix and **A**^T, **A**^H, **A**^{*}, and [**A**]_{i,j} are the transpose, Hermitian, conjugate and element (i, j) of the matrix, respectively. Also, for vector **u**, $[\mathbf{u}]_i$ shows the i^{th} element of this vector, and for vectors **u** and **v**, $\mathbf{u} \odot \mathbf{v}$ represents the element-wise multiplication of the vectors. Moreover, operators |.| and $|| \cdot ||$ return the absolute value of scalars and the norm of vectors, respectively.

II. SYSTEM MODEL

We consider a localization system comprising a single antenna Tx and N_r single antenna Rxs deployed in an environment with L scatterers (as in Fig. 1). We consider Kusers (e.g., vehicles) with unknown locations, each equipped with a linear RIS [37]–[40], whose locations trajectory and speed are to be estimated. We denote the location of the Tx, the n_r^{th} Rx and k^{th} RIS with \mathbf{p}_t , \mathbf{p}_{r,n_r} , and \mathbf{p}_k , respectively, as shown in Fig. 2. Moreover, ϕ_k , θ_{k,n_r} and ψ_{k,n_r} represent the AoA of the path between the Tx and the k^{th} RIS and the AoD of the path between the k^{th} RIS and the n_r^{th} Rx, and the orientation of the k^{th} RIS with respect to the line between the Tx and the n_r^{th} Rx, respectively. Furthermore, the steering vectors of the AoA and AoDs of the k^{th} RIS are denoted as $\mathbf{a}(\phi_k)$ and $\mathbf{a}(\theta_{k,n_r})$ for $n_r \in \mathcal{N}_r \triangleq \{1, \ldots, n_r\}$, where

$$\mathbf{a}(\psi) = [1, e^{j\frac{2\pi}{\lambda}d\cos\psi}, \dots, e^{j\frac{2\pi}{\lambda}(M-1)d\cos\psi}]^T, \qquad (1)$$

in which M is the number of the RIS elements.

The Tx sends an orthogonal frequency-division multiplexing (OFDM) signal with N sub-carriers for \overline{T} times. At the $n_r^{\rm th}$ Rx, after removing the Cyclic Prefix (CP) and applying fast Fourier transform (FFT), the received signal can be written as

$$\begin{aligned} \mathbf{y}_{n_{\mathrm{r}},\bar{t}} = &\sqrt{E_s} \sum_{k=1}^{K} g_{k,n_{\mathrm{r}}} \mathbf{d}(\tau_{k,n_{\mathrm{r}}}) \mathbf{a}(\theta_{k,n_{\mathrm{r}}})^T \boldsymbol{\Phi}_k(\bar{t}) \mathbf{a}(\phi_k) \\ &\times e^{j2\pi f_{\mathrm{d},k,n_{\mathrm{r}}} T_{\mathrm{d}}(\bar{t}-1)} + \sqrt{E_s} \sum_{\ell=0}^{L} g'_{\ell,n_{\mathrm{r}}} \mathbf{d}(\tau'_{\ell,n_{\mathrm{r}}}) + \mathbf{w}_{n_{\mathrm{r}},\bar{t}}, \\ &\forall \bar{t} \in \{1, 2, \cdots, \bar{T}\}, \end{aligned}$$

$$(2)$$

Fig. 2. Representation of locations and AoA and AoD in a scenario including the Tx, the $n^{\rm th}$ Rx, and the $k^{\rm th}$ RIS.

where E_s is the energy of the transmit signal,

$$\mathbf{d}(\tau) = [1, e^{j2\pi\Delta_f \tau}, \dots, e^{j2\pi(N-1)\Delta_f \tau}]^T,$$

 $\Phi_k(\bar{t}) \in \mathbb{C}^{M \times M}$ is the phase profile matrix of the k^{th} RIS at the \bar{t}^{th} transmission, and $\mathbf{w}_{n_r,\bar{t}}$ is the additive white Gaussian noise (AWGN) vector at the n_r^{th} Rx with power spectral density N_0 . Also, g_{k,n_r} and τ_{k,n_r} are the channel amplitude and the delay of the path between the Tx and the n_r^{th} Rx including the k^{th} RIS, respectively, and g'_{ℓ,n_r} and τ'_{ℓ,n_r} are the channel amplitude and the delay of the path between the Tx and the Tx and the n_r^{th} Rx including the ℓ^{th} scatterer, respectively ($\ell = 0$ is corresponding to the direct paths between the Tx and Rxs). Additionally, $f_{d,k,n_r} = v_k(\cos \phi_{k,n_r} + \cos \theta_{k,n_r})f_c/c$ is the Doppler frequency of the signal reflected by the k^{th} RIS and received by the n_r^{th} Rx in which v_k is the velocity of the k^{th} RIS and T_d is the symbol duration of the OFDM signal plus duration of the CP.

III. PROPOSED LOCALIZATION APPROACH

In order to investigate the tracking problem, first we need to consider measurement parameters and also design a localization approach to estimate the initial location of the RISs. In this regard, in this section, we propose a phase shift design approach and estimate the ToA and the Doppler frequency of the paths between the Tx and Rxs including the k^{th} RIS as well as parameter $\alpha_{k,n_r} \triangleq \cos \phi_k + \cos \theta_{k,n_r}$, for $k \in \mathcal{K} \triangleq \{1, \ldots, K\}$ and $n_r \in \mathcal{N}_r$. Then, using these parameters we define a least square (LS) problem to localize the k^{th} RIS. We also will employ the ToAs and α_{k,n_r} s as the measurement parameters to propose the tracking algorithm in the next section.

A. Phase shift and observation vector design

We have three purposes in the design of RIS phase shifts: (i) Be able to eliminate the effect of scatterers. (ii) Be able to separate the signals of different RISs. (iii) Be able to estimate the value of α_{k,n_r} . In this part, we design the phase shifts of the RISs in order to separate the signals reflected by various RISs at the Rxs and discriminate them from the scatterers. This enables simultaneous localization and tracking of multiple RISs from the received signals. To do this, we divide \overline{T} into N_T intervals each including T slots (i.e., $\overline{T} = N_T T$) and for $n_T \in \mathcal{N}_T \triangleq \{1, \ldots, N_T\}$ consider $\mathbf{Y}_{n_r, n_T} \in \mathbb{C}^{N \times T}$ as the matrix form of the signals received by the n_r^{th} Rx at the slots of this interval. Thus,

$$\begin{aligned} \mathbf{Y}_{n_{\rm r},n_{T}} = & \sqrt{E_s} \sum_{k=1}^{K} g_{k,n_{\rm r}} e^{j2\pi f_{{\rm d},k,n_{\rm r}}(n_{T}-1)T_{\rm d}T} \\ & \times \mathbf{d}(\tau_{k,n_{\rm r}}) [\mathbf{u}_{n_{T}}(\theta_{k,n_{\rm r}},\phi_{k}) \odot \mathbf{d}_{\rm d}(f_{{\rm d},k,n_{\rm r}})]^{T} \\ & + \sqrt{E_s} \sum_{\ell=0}^{L} g_{\ell,n_{\rm r}}' \mathbf{d}(\tau_{\ell,n_{\rm r}}') \mathbf{1}_{T}^{T} + \mathbf{W}_{n_{\rm r},n_{T}}, \end{aligned}$$
(3)

in which $[\mathbf{u}_{n_T}(\theta_{k,n_r},\phi_k)]_t = \mathbf{a}(\theta_{k,n_r})^T \mathbf{\Omega}_k(t,n_T) \mathbf{a}(\phi_k),$ where $\mathbf{\Omega}_k(t,n_T) = \mathbf{\Phi}_k((n_T - 1)T + t)$ for $t \in \mathcal{T} \triangleq \{1,\ldots,T\}, \mathbf{d}_d(f_{d,k,n_r}) = [1 \ e^{j2\pi f_{d,k,n_r}T_d} \dots e^{j2\pi f_{d,k,n_r}T_d(T-1)}]^T$, and \mathbf{W}_{n_r,n_T} is the AWGN matrix with variance $\sigma_{\mathbf{W}}^2 = \Delta_f N_0$ in which N_0 is the power spectral density.

We design the phase profile matrix of the k^{th} RIS as $\Omega_k(t, n_T) = \omega_{k,l} \Omega_k^{(n_T)}$ for $t \in \mathcal{T}$ and $n_T \in \mathcal{N}_T$, where matrix $\Omega_k^{(n_T)}$ is constant during each T transmissions. We set vectors $\omega_k = [\omega_{k,1}, \ldots, \omega_{k,T}]^T$, $k \in \mathcal{K}$, such that $\forall t \in \{1, \ldots, T/2\}, \omega_{k,2t} = -\omega_{k,2t-1}$ and vectors $\gamma_k = [\omega_{k,1}, \omega_{k,3}, \ldots, \omega_{k,T-1}]^T$, for $k \in \mathcal{K}$ be orthogonal to each other. To satisfy the orthogonality, vectors γ_k can be chosen from the set of the columns of the FFT matrix with dimensions T/2. In practice, to not to be have to update the dimensions of the FFT matrix when the number of the RISs increases, we consider a maximum number for the RISs and set the dimensions of the FFT matrix by this number.

Now, let us separate matrix \mathbf{Y}_{n_r,n_T} into sub-matrices $\mathbf{Y}_{n_r,n_T,o}$ and $\mathbf{Y}_{n_r,n_T,e}$ that contain the odd and even columns, respectively. Considering that the scatterers are fixed during transmissions and thus the terms of the scatterers are the same in the odd and even columns, while by designing $\omega_{k,2t} = -\omega_{k,2t-1}$ for $t \in \{1, ..., T/2\}$, the terms corresponding to the RISs are opposite, we can remove the contributions of the scatterers by computing

$$\mathbf{Y}'_{n_{\rm r},n_T} = \frac{1}{2} (\mathbf{Y}_{n_{\rm r},n_T,o} - \mathbf{Y}_{n_{\rm r},n_T,e}).$$
(4)

B. Joint Estimation of τ_{k,n_r} and f_{d,k,n_r}

To estimate τ_{k,n_r} and f_{d,k,n_r} , we first extract the signal of the k^{th} RIS. Neglecting the effect of the Doppler shifts, considering the orthogonality of γ_k s, we extract the n_T^{th} signal vector received through the path including the k^{th} RIS, by computing $\mathbf{r}_{k,n_r,n_T} = \frac{2}{T} \mathbf{Y}'_{n_r,n_T} \gamma_k^*$. Thus,

$$\mathbf{r}_{k,n_{\rm r},n_{T}} = \sqrt{E}_{s} \ g_{k,n_{\rm r}} \mathbf{d}(\tau_{k,n_{\rm r}}) \mathbf{a}(\theta_{k,n_{\rm r}})^{T} \mathbf{\Omega}_{k}^{(n_{T})} \mathbf{a}(\phi_{k}) \times e^{j2\pi f_{{\rm d},k,n_{\rm r}}(n_{T}-1)T_{\rm d}T} \sum_{t=1}^{T/2} \left(1 + e^{j2\pi f_{{\rm d},k,n_{\rm r}}T_{\rm d}(t-1)}\right) + \mathbf{z}_{k,n_{\rm r},n_{T}},$$
(5)

in which $\mathbf{z}_{k,n_{r},n_{T}} = \frac{2}{T} \mathbf{W}'_{n_{r},n_{T}} \boldsymbol{\gamma}_{k}^{*} + \mathcal{I}_{k,n_{r},n_{T}}$, where $\mathcal{I}_{k,n_{r},n_{T}}$ is the leakage of the signals corresponding to the other RISs.

Algorithm 1 Proposed Doppler frequency and ToA Estimation Scheme

1: for $n_{\rm r} = 1$ to $N_{\rm r}$ do for k = 1 to K do 2: Set 3: $[n_{1,\tau}^*, n_{1,f_{\mathrm{d}}}^*] = \arg \max \left| \left[\mathbf{F}_{\tau} \mathbf{R}_{k,n_{\mathrm{r}}} \mathbf{F}_{f_{\mathrm{d}}}^T \right]_{n_{1,\tau},n_{1,f_{\mathrm{d}}}} \right|$ Compute $\hat{\tau}_{k,n_{\mathrm{r}}} = (n_{1,\tau}^* - 1)/(N_{F_{\tau}}\Delta_f)$ and 4: $\hat{f}_{\mathrm{d},k,n_{\mathrm{r},1}} = (2n_{1,f_{\mathrm{d}}}^{*} - 1)c/(2TT_{\mathrm{d}}f_{c}).$ Set 5: $[n_{2,\tau}^*, n_{2,f_{\mathrm{d}}}^*] = \arg \max \left| \left[\mathbf{F}_{\tau} \mathbf{R}_{k,n_{\mathrm{r}}} \mathbf{F}_{f_{\mathrm{d}}}^T \right]_{n_{2,\tau}, n_{1,f_{\tau}}} \right|$ Compute $\hat{f}_{{\rm d},k,n_{\rm r},2} = -(2n^*_{2,f_{\rm d}}-1)c/(2TT_{\rm d}f_c).$ 6: if $|f_{d,k,n_r,1}| < |f_{d,k,n_r,2}|$ then 7: $\hat{f}_{\mathrm{d},k,n_{\mathrm{r}}} = \hat{f}_{\mathrm{d},k,n_{\mathrm{r}},1}.$ else 8: 9: $\hat{f}_{\mathrm{d},k,n_{\mathrm{r}}}=\hat{f}_{\mathrm{d},k,n_{\mathrm{r}},2}.$ end if 10:

11:

end for 12:

13: end for

We must note that neglecting the Doppler shifts to be able to exactly extract the signal reflected by each RIS as (5), Tshould satisfy $K \leq T/2$.

Now, considering the design of matrix $\Omega_{k}^{(n_T)}$ in which for $n_T \in \{1, \ldots, N_T/2\}$ and $m \neq 2$, $\Omega_{k,m,m}^{(2n_T-1)} = \Omega_{k,m,m}^{(2n_T)}$ and $\Omega_{k,2,2}^{(2n_T-1)} \neq \Omega_{k,2,2}^{(2n_T)}$ (See Section III-C), we subtract the concepting supervised of Mthe consecutive vectors i.e., $\mathbf{r}_{k,n_r,2n_T-1}$ and $\mathbf{r}_{k,n_r,2n_T}$ for $n_T \in \{1, \ldots, N_T/2\}$ to obtain a set of vectors that their phase shifts compared to each other is just the Doppler shift as blow

$$\mathbf{r}'_{k,n_{\rm r},n_T} = \mathbf{r}_{k,n_{\rm r},2n_T-1} - \mathbf{r}_{k,n_{\rm r},2n_T}, \forall n_T \in \{1,\dots,N_T/2\}.$$
(6)

Then, we construct matrix $\mathbf{R}_{k,n_{\mathrm{r}}} = [\mathbf{r}_{k,n_{\mathrm{r}},1}' \ldots \mathbf{r}_{k,n_{\mathrm{r}},N_{T}/2}'] \in$ $\mathcal{C}^{N imes N_T/2}$ in which the difference of the phase shifts of the consecutive elements on each column is $2\pi\Delta_f \tau_{k,n_r}$ and the difference of the phase shifts the consecutive elements on each row is equal to $4\pi f_{d,k,nr}T_dT$. We aim to employ 2DFFT of signal $\mathbf{r}_{k,n_{r},n_{T}}$ to jointly estimate $\tau k, n_{r}$ and $f_{d,k,n_{r}}$. But, the challenge is that the sign of f_{d,k,n_r} is unknown¹. To solve this problem, assuming that $|4\pi f_{d,k,n_r} T_d T| < 2\pi - |4\pi f_{d,k,n_r} T_d T|$, we propose algorithm 1 to jointly estimate τ_{k,n_r} and f_{d,k,n_r} . In this algorithm, $\mathbf{F}_{\tau} \in C^{N_{f,\tau} \times N}$ and $\mathbf{F}_{f_d,1} \in C^{N_{f,f_d} \times N_T/2}$ are FFT matrices, and $\mathbf{F}_{f_d,2} \in C^{N_{f,f_d} \times N_T/2}$ is an IFFT matrix. In this algorithm, we use this subject that if we one time estimate f_{d,k,n_r} employing the FFT matrix and one time with IFFT matrix, the estimated values satisfy

$$|4\pi f_{d,k,n_{r,1}}T_{d}T| = 2\pi - |4\pi f_{d,k,n_{r,2}}T_{d}T|.$$

¹Because the value of $f_{\mathrm{d},k,n_\mathrm{r}}$ depends on the position of the RIS and depending on it $f_{\mathrm{d},k,n_\mathrm{r}}$ can get a positive or a negative value.

C. Estimation of α_{k,n_r}

In order to estimate α_{k,n_r} , we first remove the effect of f_{d,k,n_r} and τ_{k,n_r} . To eliminate the effect of Doppler shifts, for each $k \in \mathcal{K}$, $n_T \in \mathcal{N}_T$ and $n_r \in \mathcal{N}_r$, we construct semiorthogonal vectors $\gamma_{k,n_{\mathrm{r}},n_{\mathrm{T}}}$, by pointwise multiplication of vectors γ_k s and vectors

$$e^{j2\pi \hat{f}_{\mathrm{d},k,n_{r}}T_{\mathrm{d}}T(n_{T}-1)} \times \left[(1+e^{j2\pi \hat{f}_{\mathrm{d},k,n_{r}}T_{\mathrm{d}}}), \dots, (e^{j2\pi \hat{f}_{\mathrm{d},k,n_{r}}T_{\mathrm{d}}(T/2-1)}+e^{j2\pi \hat{f}_{\mathrm{d},k,n_{r}}T_{\mathrm{d}}T/2}) \right]_{,}^{T}$$

for $k \in \mathcal{K}^2$. Then, we simultaneously extract the signal of the $k^{\rm th}$ RIS and remove the effect of the Doppler shift and $\tau_{k,n_{\rm r}}$ by obtaining

$$\mathbf{r}_{k,n_{\mathrm{r}},n_{T}}^{\prime\prime} = \frac{2}{T} (\mathbf{Y}_{n_{\mathrm{r}},n_{T}}^{\prime} \boldsymbol{\gamma}_{k,n_{\mathrm{r}},n_{T}}) \odot \mathbf{d}(\hat{\tau}_{k,n_{\mathrm{r}}}) \qquad(7)$$
$$\simeq s_{k,n_{\mathrm{r}},n_{T}} \mathbf{1}_{N} + \mathbf{z}_{k,n_{\mathrm{r}},n_{T}}^{\prime},$$

in which $s_{k,n_{\rm r},n_T} \triangleq \sum_{m=1}^M \sqrt{E}_s g_{k,n_{\rm r}} \Omega_{k,m,m}^{(n_T)} e^{j\frac{2\pi}{\lambda}(m-1)d\alpha_{k,n_{\rm r}}}$ and $\mathbf{z}'_{k,n_{\rm r},n_T}$ the AWGN vector.

Regarding invariance property of the ML estimation approach³, we first estimate s_{k,n_r,n_T} , and then use it to obtain the estimated value of α_{k,n_r} . The ML estimation of s_{k,n_r,n_T} for $n_T \in \mathcal{N}_T$ and $n_r \in \mathcal{N}_r$ is

$$\hat{s}_{k,n_{\rm r},n_T} = \frac{1}{N} \sum_{n=1}^{N} [\mathbf{r}_{k,n_{\rm r},n_T}'']_n.$$
 (8)

Now, for $n_{\rm r} \in \mathcal{N}_{\rm r}$ we can obtain $\hat{\alpha}_{k,n_{\rm r}}$, by solving the following system of non-linear equations

$$\sum_{m=1}^{M} \sqrt{E}_{s} g_{k,n_{r}} \Omega_{k,m,m}^{(N_{T})} e^{j\frac{2\pi}{\lambda}(m-1)d\alpha_{k,n_{r}}} = \hat{s}_{k,n_{r},n_{T}}, \forall n_{T} \in \mathcal{N}_{T}.$$
(9)

Regarding the degree of each equation in terms of $e^{j\frac{2\pi}{\lambda}d\alpha_{k,n_{\rm r}}}$, there exist up to M-1 distinct values for $\alpha_{k,n_{\rm r}}$ in each interval of length $\frac{\lambda}{d}$ satisfying this equation system. Consequently, we generally have ambiguity to estimate the correct value of α_{k,n_r} . To address this challenge, we design $\Omega_{k,m,m}^{(n_T)}$ for $n_T \in \mathcal{N}_T$ and $m \in \{2,\ldots,M\}$ and employ the elimination approach such that the correct value of α_{k,n_r} is distinguishable. For simplicity, we perform this task in such a way that only one of the powers of $e^{j\frac{2\pi}{\lambda}d\alpha_{k,n_{r}}}$ remains.

Considering that the RISs can have orientation generally $-2 < \alpha_{k,n_{\rm r}} < 2$. Thus, assuming that $d = \frac{\lambda}{L}$, the value of $\frac{2\pi}{\lambda}(m-1)d\alpha_{k,n_{\rm r}}$ is in the range $[-(m-1)\frac{\pi}{L},(m-1)\frac{\pi}{L}]$. Therefore, the remained exponent of $e^{j\frac{2\pi}{\lambda}d\alpha_{k,n_{r}}}$ (M') should be equal or less than L, where $L \ge 4$ to ensure that $\frac{2\pi}{\lambda}M'd\alpha_{k,n_r}$ is in $(-\pi,\pi)$ and thus the correct value of α_{k,n_r} is distinguishable⁴. To ensure that our system works for all values of L that satisfy this constraint, we design the phase shifts such that for $n_T \in \{1, \ldots, N_T/2\}$ and

²The vectors will be orthogonal when the length of them tends to infinity. ³The invariance property states that if $\hat{\theta}$ is the ML estimation of the θ , then for function f the ML estimation of $f(\theta)$ is $f(\hat{\theta})$ [41].

⁴Actually, under this condition we ensure that in an equation such as $e^{j\frac{2\pi}{M}'\lambda d\alpha_{k,n_{\rm r}}} = c_0$ the value of $\alpha_{k,n_{\rm r}}$, is equal to $\frac{\lambda}{M'd}\arg\{c_0\}$, and do not have ambiguity between values $\frac{\lambda}{M'd}\arg\{c_0\} + 2k\pi/M'$.

Algorithm 2 Proposed RIS Localization Approach

1: The transmitter sends the signal for \overline{T} times. 2: for $n_{\rm r} = 1$ to $N_{\rm r}$ do for $n_T = 1$ to N_T do 3: Construct matrix $\mathbf{Y}_{n_{r},n_{T}}$ and calculate $\mathbf{Y}'_{n_{r},n_{T}}$ 4: $\frac{1}{2}(\mathbf{Y}_{n_{\mathrm{r}},n_{T},o}-\mathbf{Y}_{n_{\mathrm{r}},n_{T},e})$ to remove the effect of the scatters. for k = 1 to K do 5: Extracts the signal reflected by the k^{th} RIS by 6: computing $\mathbf{r}_{k,n_{\mathrm{r}},n_{T}} = \frac{2}{T} \mathbf{Y}'_{n_{\mathrm{r}},n_{T}} \boldsymbol{\gamma}_{k}^{*}$. end for 7: end for 8: for k = 1 to K do 9: for $n_T = 1$ to N_T do 10: Obtain signal \mathbf{r}'_{k,n_r,n_T} using 6. 11: end for 12: Estimate τ_{k,n_r} and f_{d,k,n_r} using algorithm 1. 13: Remove the effect of τ_{k,n_r} using (7). 14: for $n_T = 1$ to N_T do 15: Estimate s_{k,n_r,n_T} using (8). 16: 17: end for 18: Estimate α_{k,n_r} using (12). 19: end for 20: end for 21: **for** k = 1 to K **do** Define problem (15) by substituting $\hat{\tau}_{k,n_r}$ and $\hat{\alpha}_{k,n_r}$ and 22: solve it to estimate the location of the k^{th} RIS. 23: end for

 $m \neq 2$, $\Omega_{k,m,m}^{(2n_T-1)} = \Omega_{k,m,m}^{(2n_T)}$ and $\Omega_{k,2,2}^{(2n_T-1)} \neq \Omega_{k,2,2}^{(2n_T)}$. Thus, subtracting the consecutive equations in (9), we obtain the following system of equations

$$g_{k,n_{r}}e^{j\frac{2\pi d}{\lambda}\alpha_{k,n_{r}}} = \frac{1}{\Omega_{k,2,2}^{(N_{T}-1)} - \Omega_{k,2,2}^{(N_{T})}} (\hat{s}_{k,n_{r},n_{T}-1} - \hat{s}_{k,n_{r},n_{T}}),$$

$$n_{T} \in \{2,\dots,N_{T}\}.$$
 (10)

Then, we formulate the following LS problem to estimate α_{k,n_r}

$$\min_{\alpha_{k,n_{\rm r}}\in\mathbb{R}} \sum_{n_T=1}^{N_T/2} \left| g_{k,n_{\rm r}} e^{j\frac{2\pi d}{\lambda}\alpha_{k,n_{\rm r}}} - \frac{\hat{s}_{k,n_{\rm r},2n_T-1} - \hat{s}_{k,n_{\rm r},2n_T}}{\Omega_{k,2,2}^{(2n_T-1)} - \Omega_{k,2,2}^{(2n_T)}} \right|^2, \tag{11}$$

and thus, the optimal value of α_{k,n_r} can be derived as

$$\hat{\alpha}_{k,n_{\rm r}} = \frac{\lambda}{2\pi d} \arg\left(\frac{1}{N_T} \sum_{n_T=1}^{N_T/2} \frac{\hat{s}_{k,n_{\rm r},2n_T-1} - \hat{s}_{k,n_{\rm r},2n_T}}{\Omega_{k,2,2}^{(2n_T-1)} - \Omega_{k,2,2}^{(2n_T)}}\right).$$
(12)

D. The Localization Approach

Now, we aim to define an LS problem considering the estimated values of τ_{k,n_r} and α_{k,n_r} for $n_r \in \mathcal{N}_r$, to localize the k^{th} RIS. In this regard, we first derive the equation of τ_{k,n_r} and α_{k,n_r} in terms of the location of the RIS.

Algorithm 3 Proposed EKF-based RIS Tracking Approach

- 1: Initialization: For $k \in \mathcal{K}$, estimate $\mathbf{x}_k[0|0]$ employing algorithm 2. Set n = 1.
- 2: while Tracking the RISs do
- 3: for k = 1 to K do
- 4: Predict the location and velocity of the k^{th} RIS as follows:

$$\mathbf{x}_k[n|n-1] = \mathbf{A} \mathbf{x}_k[n-1|n-1] + \mathbf{B} \mathbf{a}_k.$$

5: Obtain the minimum prediction mean square error (MSE) matrix:

$$\mathbf{M}_k[n|n-1] = \mathbf{A}\mathbf{M}_k[n-1|n-1]\mathbf{A}^T + \mathbf{Q}_k[n].$$

6: Construct vector $\mathbf{h}(\mathbf{x}_k[n])$ as

$$\mathbf{h}(\mathbf{x}_{k}[n]) = \begin{bmatrix} \|\mathbf{p}_{k}[n] - \mathbf{p}_{t}\| + \|\mathbf{p}_{k}[n] - \mathbf{p}_{r,1}\| \\ \vdots \\ \|\mathbf{p}_{k}[n] - \mathbf{p}_{t}\| + \|\mathbf{p}_{k}[n] - \mathbf{p}_{r,N_{r}}\| \\ \frac{|p_{k,1}[n] - p_{t,1}|}{\|\mathbf{p}_{k}[n] - \mathbf{p}_{t}\|} - \frac{|p_{k,1}[n] - p_{r,1,1}|}{\|\mathbf{p}_{k}[n] - \mathbf{p}_{r,1}\|} \\ \vdots \\ \frac{|p_{k,1}[n] - p_{t,1}|}{\|\mathbf{p}_{k}[n] - \mathbf{p}_{t}\|} - \frac{|p_{k,1}[n] - p_{r,N_{r},1}|}{\|\mathbf{p}_{k}[n] - \mathbf{p}_{r,N_{r}}\|} \end{bmatrix}.$$

7: Obtain matrix
$$\mathbf{H}_k[n]$$
 as

$$\mathbf{H}_{k}[n|n-1] = \frac{\partial \mathbf{h}(\mathbf{x}_{k}[n])}{\partial \mathbf{x}_{k}[n]} \Big|_{\mathbf{x}_{k}[n] = \mathbf{x}_{k}[n|n-1]}.$$

8: Calculate the Kalman gain matrix as

$$\begin{aligned} \mathbf{K}_{k}[n] &= \mathbf{M}_{k}[n|n-1]\mathbf{H}_{k}^{H}[n] \\ &\times \left(\mathbf{C}_{k}[n] + \mathbf{H}_{k}[n]\mathbf{M}_{k}[n|n-1]\mathbf{H}_{k}^{H}[n]\right)^{-1}. \end{aligned}$$

for $n_{\rm r} = 1$ to $N_{\rm r}$ do

Estimate τ_{k,n_r} using algorithm 1. Estimate α_{k,n_r} as follows:

$$\hat{\alpha}_{k,n_{\rm r}} = \frac{\lambda}{2\pi d} \arg\left(\frac{1}{N_T} \sum_{n_T=1}^{N_T/2} \frac{\hat{s}_{k,n_{\rm r},2n_T-1} - \hat{s}_{k,n_{\rm r},2n_T}}{\Omega_{k,2,2}^{(2n_T-1)} - \Omega_{k,2,2}^{(2n_T)}}\right).$$

end for

9.

10:

11:

12:

13:

14:

Construct the measurement vector $\boldsymbol{\nu}_k[n]$ using $\hat{\tau}_{k,n_r}$ and $\hat{\alpha}_{k,n_r}$, $n_r \in \mathcal{N}_r$.

Correct the estimation of position and velocity of the RIS as

$$\mathbf{x}_{k}[n|n] = \mathbf{x}_{k}[n|n-1] + \mathbf{K}_{k}[n](\boldsymbol{\nu}_{k}[n] - \mathbf{h}(\hat{\mathbf{x}}_{k}[n|n-1]))$$

15: Obtain the minimum MSE matrix

$$\mathbf{M}_k[n|n] = (\mathbf{I} - \mathbf{K}_k[n]\mathbf{H}_k[n])\mathbf{M}_k[n|n-1].$$

16: end for 17: Set n = n + 1. 18: end while Defining c as the speed of light, we have

$$\|\mathbf{p}_{k} - \mathbf{p}_{t}\| + \|\mathbf{p}_{k} - \mathbf{p}_{r,n_{r}}\| = c\tau_{k,n_{r}}.$$
 (13)

Also, defining ϕ'_{k,n_r} and θ'_{k,n_r} as shown in Fig. 2, we have $\phi_{k,n_r} = \phi'_{k,n_r} - \psi_{k,n_r}$ and $\theta_{k,n_r} = \theta'_{k,n_r} - \psi_{k,n_r}$, and using it the value of α_{k,n_r} would be equal to

$$\alpha_{k,n_{\rm r}} = \cos \psi_{k,n_{\rm r}} \left(\frac{|p_{k,1} - p_{{\rm t},1}|}{\|\mathbf{p}_{k} - \mathbf{p}_{{\rm t}}\|} - \frac{|p_{k,1} - p_{{\rm r},n_{\rm r},1}|}{\|\mathbf{p}_{k} - \mathbf{p}_{{\rm r},n_{\rm r}}\|} \right) + \\ \sin \psi_{k,n_{\rm r}} \left(\frac{|p_{k,2} - p_{{\rm t},2}|}{\|\mathbf{p}_{k} - \mathbf{p}_{{\rm t}}\|} + \frac{|p_{k,2} - p_{{\rm r},n_{\rm r},2}|}{\|\mathbf{p}_{k} - \mathbf{p}_{{\rm r},n_{\rm r}}\|} \right), \quad (14)$$

where $p_{k,1} = [\mathbf{p}_k]_1$, $p_{k,2} = [\mathbf{p}_k]_2$, $p_{t,1} = [\mathbf{p}_t]_1$, $p_{t,2} = [\mathbf{p}_t]_2$, $p_{r,n_r,1} = [\mathbf{p}_{r,n_r}]_1$, and $p_{r,n_r,2} = [\mathbf{p}_{r,n_r}]_2$. Now, considering the estimated values of τ_{k,n_r} and α_{k,n_r} and equations (13) and (14), we define the following LS problem to localize the k^{th} RIS

$$\min_{\mathbf{p}_{k}} \sum_{n_{r}=1}^{i} \left(\left\| \mathbf{p}_{k} - \mathbf{p}_{t} \right\| + \left\| \mathbf{p}_{k} - \mathbf{p}_{r,n_{r}} \right\| - c\hat{\tau}_{k,n_{r}} \right|^{2} + \left\| \cos\psi_{k,n_{r}} \left(\frac{|p_{k,1} - p_{t,1}|}{\|\mathbf{p}_{k} - \mathbf{p}_{t}\|} - \frac{|p_{k,1} - p_{r,n_{r},1}|}{\|\mathbf{p}_{k} - \mathbf{p}_{r,n_{r}}\|} \right) + (15) \\ \sin\psi_{k,n_{r}} \left(\frac{|p_{k,2} - p_{t,2}|}{\|\mathbf{p}_{k} - \mathbf{p}_{t}\|} + \frac{|p_{k,2} - p_{r,n_{r},2}|}{\|\mathbf{p}_{k} - \mathbf{p}_{r,n_{r}}\|} \right) - \hat{\alpha}_{k,n_{r}} \right|^{2} \right),$$

which can be solved by quasi-Newton approaches.

Algorithm 2 summarizes the proposed localization approach. Considering the number of multiplications in extracting signal $\mathbf{r}_{k,n_{\mathrm{r}},n_{T}}$, the number of multiplications in algorithm 2, the number of multiplications in obtaining signal $\mathbf{r}_{k,n_{\mathrm{r}},n_{T}}^{\prime\prime}$ and the order of complexity of finding $n_{f,f_{\mathrm{d}}}$ and $n_{f,\tau}$ in algorithm 1, the computational complexity of this localization approach is of the order of $\mathcal{O}\left(KN_{\mathrm{r}}(NN_{T}+N_{T}N_{f,\tau}N_{f,f_{\mathrm{d}}}+N_{f,\tau}N_{f,f_{\mathrm{d}}}\log(N_{f,\tau}N_{f,f_{\mathrm{d}}})\right)$.

IV. PROPOSED TRACKING APPROACH

We propose an EKF-based approach for tracking the RISs. In this regard, let us define \mathbf{a}_k as the acceleration vector of the k^{th} RIS. We consider the fixed acceleration state model for the location and velocity of the RIS as follows

$$\mathbf{x}_{k}[n] = \begin{bmatrix} \mathbf{p}_{k}[n] \\ \mathbf{v}_{k}[n] \end{bmatrix} = \begin{bmatrix} \mathbf{p}_{k}[n-1] + T_{s}\mathbf{v}_{k}[n-1] + \frac{1}{2}T_{s}^{2}\mathbf{a}_{k} \\ \mathbf{v}_{k}[n-1] + T_{s}\mathbf{a}_{k} \end{bmatrix} + \mathbf{u}_{k,1}[n],$$
(16)

in which $\mathbf{v}_k[n]$ is the velocity of the RIS at the n^{th} step, T_s is the tracking step time, and $\mathbf{u}_{k,1}[n]$ is AWGN. We must note that in the fixed acceleration model, actually the variation of the direction of the RISs is assumed to be fixed. But, the tracking system can adapt itself for the cases that the variation of the direction is not fixed, by updating the value of acceleration. Thus, the considered model can support paths with different velocities and directions. Let, define

$$\mathbf{A} = \begin{bmatrix} 1 & 0 & T_s & 0 \\ 0 & 1 & 0 & T_s \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \text{ and } \mathbf{B} = \begin{bmatrix} \frac{T_s^2}{2} & 0 & T_s & 0 \\ 0 & \frac{T_s^2}{2} & 0 & T_s \end{bmatrix}^T, \text{ the }$$

state model can be rewritten as

$$\mathbf{x}_{k}[n] = \mathbf{A} \ \mathbf{x}_{k}[n-1] + \mathbf{B} \ \mathbf{a}_{k} + \mathbf{u}_{k,1}[n].$$
(17)

Fig. 3. The localization error of the proposed approach for different number of Rxs in terms of (a): Subcarrier bandwidth. (b): Number of subcarriers. (c): Total transmit power (NE_s) . The RIS location is [7, 7].

Additionally, defining ξ_{k,n_r} as the length of the path between the transmitter and the n_r^{th} Rx including the k^{th} RIS, we consider the vector $\boldsymbol{\nu}_k[n] = \left[\hat{\xi}_{k,1}[n], \dots, \hat{\xi}_{k,N_r}[n], \hat{\alpha}_{k,1}[n], \dots, \hat{\alpha}_{k,N_r}[n]\right]^T$ as the measurement vector and model it as

$$\boldsymbol{\nu}_{k}[n] = \underbrace{\begin{bmatrix} \|\mathbf{p}_{k}[n] - \mathbf{p}_{t}\| + \|\mathbf{p}_{k}[n] - \mathbf{p}_{r,1}\| \\ \vdots \\ \|\mathbf{p}_{k}[n] - \mathbf{p}_{t}\| + \|\mathbf{p}_{k}[n] - \mathbf{p}_{r,N_{r}}\| \\ \frac{\|p_{k,1}[n] - p_{t,1}\|}{\|\mathbf{p}_{k}[n] - \mathbf{p}_{t}\|} - \frac{\|p_{k,1}[n] - p_{r,1,1}\|}{\|\mathbf{p}_{k}[n] - \mathbf{p}_{r,1}\|} \\ \vdots \\ \frac{\|p_{k,1}[n] - p_{t,1}\|}{\|\mathbf{p}_{k}[n] - \mathbf{p}_{t}\|} - \frac{\|p_{k,1}[n] - p_{r,N_{r},1}\|}{\|\mathbf{p}_{k}[n] - \mathbf{p}_{r,N_{r}}\|} \end{bmatrix}}_{\mathbf{h}(\mathbf{x}_{k}[n])}$$
(18)

in which $\mathbf{u}_{k,2}[n]$ is AWGN.

It is noticeable that the measurement vector is not linear. Hence, we first linearise the equation of the measurement

Fig. 4. The localization error of the proposed approach in terms of (a): N_T (b): T. The RIS location is [7, 7].

vector, by defining

$$\mathbf{H}_{k}[n|n-1] = \frac{\partial \mathbf{h}(\mathbf{x}_{k}[n])}{\partial \mathbf{x}_{k}[n]} \Big|_{\mathbf{x}_{k}[n] = \mathbf{x}_{k}[n|n-1]}, \quad (19)$$

which is obtained in Appendix A.

Subsequently, defining $\mathbf{Q}_k[n] = \mathbb{E}{\{\mathbf{u}_{k,1}[n]\mathbf{u}_{k,1}[n]^H}}$ and $\mathbf{C}_k[n] = \mathbb{E}{\{\mathbf{u}_{k,2}[n]\mathbf{u}_{k,2}[n]^H}}$ and regarding the EKF approach [41], we propose Algorithm 3 to track the location of the RISs. Let, $\mathbf{M}_k[n|n-1]$, $\mathbf{K}_k[n]$, and $\mathbf{M}_k[n|n]$ represent the minimum prediction MSE, the Kalman gain, and the minimum MSE matrices at the n^{th} step of the tracking process, respectively. In this algorithm, at the first step, we estimate $\mathbf{x}_k[0|0]$, the initial location of the kth RIS, using Algorithm 2. Then, at each tracking process, we first predict the location of the RIS conditioned on the previous measurements. Next, we obtain the minimum prediction MSE matrix and use it to calculate the Kalman gain matrix. Then, we correct the location of the RIS employing the Kalman matrix gain and matrix $\mathbf{H}_k[n]$. Finally, we obtain the minimum MSE matrix to be used for the next tracking process.

We can notice that the computational complexity of algorithm 3 considering the number multiplications in estimating the measurement parameters, and the complexity of Kalman filtering, which is of the order of number of the measurement parameters to the power of 2.4 [41], is of the order of $\mathcal{O}(KN_{\rm r}(NN_T+N_TN_{f,\tau}N_{f,f_{\rm d}}+N_{f,\tau}N_{f,f_{\rm d}}\log(N_{f,\tau}N_{f,f_{\rm d}})+2^{2.4}N_{\rm r}^{1.4}).$

V. CRAMER-RAO LOWER BOUNDS

In this section, we obtain the CRLB of the location of the k^{th} RIS. Since our approach relies on the ToA and geometric parameters, we also derive the CRLBs of the ToA between

Fig. 5. The localization error in terms of (a): Subcarrier bandwidth. (b): Number of subcarriers. (c): Total transmit power (NE_s) . The RIS location is [7, 7].

the transmitter and the $n_{\rm r}^{\rm th}$ receiver through the $k^{\rm th}$ RIS, i.e., $\tau_{k,n_{\rm r}}$, along with the geometric parameters $\alpha_{k,n_{\rm r}}$, for $n_{\rm r} \in \mathcal{N}_{\rm r}$. Considering the original received signal as the observation vector, we define vector $\bar{\mathbf{y}} \in \mathcal{C}^{N\bar{T}N_{\rm r}\times 1}$, such that $[\bar{\mathbf{y}}]_{\gamma_1(n,\bar{t},n_{\rm r})} = [\mathbf{y}_{n_{\rm r},\bar{t}}]_n$, where $\mathbf{y}_{n_{\rm r},\bar{t}}$ is defined in (2) and $\gamma_1(n,\bar{t},n_{\rm r}) = n + N(\bar{t}-1) + N\bar{T}(n_{\rm r}-1)$.

A. CRLB of \mathbf{p}_k

To calculate this, we define

$$\boldsymbol{\eta} = [p_{1,1}, p_{1,2}, g_{1,1}, f_{\mathrm{d},1,1}, \dots, g_{k,N_{\mathrm{r}}}, f_{\mathrm{d},1,N_{\mathrm{r}}}, \dots, p_{K,1}, p_{K,2}, g_{K,1}, f_{\mathrm{d},K,1}, \dots, g_{K,N_{\mathrm{r}}}, f_{\mathrm{d},K,N_{\mathrm{r}}}]^{T}.$$

Fig. 6. The localization error as the total bandwidth is fixed in terms of (a): Subcarrier bandwidth. (b): Number of subcarriers. The RIS location is [7, 7].

The vector $\bar{\mathbf{y}}$ can be represented as $\bar{\mathbf{y}} = \mathbf{f} + \mathbf{z}$ where

$$\begin{aligned} [\mathbf{f}]_{\gamma_1(n,\bar{t},n_{\mathrm{r}})} &= \sum_{k=1}^K \sqrt{E_s} \ g_{k,n_{\mathrm{r}}} e^{j2\pi(n-1)\Delta f\tau_{k,n_{\mathrm{r}}}} \\ &\times e^{j2\pi f_{\mathrm{d},k,n_{\mathrm{r}}}T_{\mathrm{d}}(\bar{t}-1)} \sum_{m=1}^M [\mathbf{\Phi}_k(\bar{t})]_{m.m} e^{j\frac{2\pi}{\lambda}(m-1)d\alpha_{k,n_{\mathrm{r}}}}. \end{aligned}$$
(20)

Therefore, the $(i, j)^{\text{th}}$ component of $\mathbf{I}_{\boldsymbol{\eta}}$, the information matrix of $\boldsymbol{\eta}$, is equal to [41]

$$\left[\mathbf{I}\boldsymbol{\eta}\right]_{i,j} = 2\mathcal{R}\left\{\left[\frac{\partial \mathbf{f}}{\partial \eta_i}\right]^H \mathbf{Q}_{\mathbf{z}}^{-1}\left[\frac{\partial \mathbf{f}}{\partial \eta_j}\right]\right\},\,$$

in which $\mathbf{Q}_{\mathbf{z}}$ is the covariance matrix of vector \mathbf{z} . Now, define $\gamma_2(k, n_r) = (k-1)n_r$ and

$$\mu(n,k,n_{\rm r},m) = e^{j2\pi((n-1)\Delta f\tau_{k,n_{\rm r}} + f_{{\rm d},k,n_{\rm r}}T_{\rm d}(\bar{t}-1) + \frac{1}{\lambda}(m-1)d\alpha_{k,n_{\rm r}})}.$$

For $k \in \mathcal{K}$, $n_r \in \mathcal{N}_r$, and $i' \in \{1, 2\}$ the element $\gamma_1(n, \bar{t}, n_r)$ of $\frac{\partial \mathbf{f}}{\partial \eta_i}$ for $i = 2\gamma_2(k, N_r + 1) + 1$ and $i = 2\gamma_2(k, N_r + 1) + 2$ is as (21), in which the partial derivatives of α_{k,n_r} and τ_{k,n_r} , are given as obtained in appendix A. Also, for $i = 2\gamma_2(k, N_r + 1) + 2n_r + 1$ the elements of the vector $\frac{\partial \mathbf{f}}{\partial \eta_i}$ are equal to

$$\left[\frac{\partial \mathbf{f}}{\partial \eta_{2\gamma_2(k,N_{\mathrm{r}}+1)+2n_{\mathrm{r}}+1}}\right]_{\gamma_1(n,\bar{t},n_{\mathrm{r}})} \sum_{m=1}^M [\mathbf{\Phi}_k(\bar{t})]_{m,m} \mu(n,k,n_{\mathrm{r}},m),$$
(22)

and for $i = 2\gamma_2(k, N_r + 1) + 2n_r + 2$ the elements of this vector are as

$$\left[\frac{\partial \mathbf{f}}{\partial \eta_{2\gamma_{2}(k,N_{\mathrm{r}}+1)+2n_{\mathrm{r}}+2}}\right]_{\gamma_{1}(n,\bar{t},n_{\mathrm{r}})} = (23)$$

$$\sqrt{E_{s}}g_{k,n_{\mathrm{r}}}(j2\pi T_{\mathrm{d}}(\bar{t}-1))\sum_{m=1}^{M}\left[\mathbf{\Phi}_{k}(\bar{t})\right]_{m,m}\mu(n,k,n_{\mathrm{r}},m).$$

The CRLB of \mathbf{p}_k is equal to to tr $\{\mathbf{J}_{\boldsymbol{\eta},2\gamma_2(k,N_r+1)+1:2\gamma_2(k,N_r+1)+2}\}$, in which $\mathbf{J}_{\boldsymbol{\eta}} = \mathbf{I}_{\boldsymbol{\eta}}^{-1}$ and we have

 $\mathbf{J}_{\eta,2\gamma_{2}(k,N_{r}+1)+1:2\gamma_{2}(k,N_{r}+1)+2}$

$$= \begin{bmatrix} J_{\eta,2\gamma_{2}(k,N_{r}+1)+1,2\gamma_{2}(k,N_{r}+1)+1} & J_{\eta,2\gamma_{2}(k,N_{r}+1)+1,2\gamma_{2}(k,N_{r}+1)+2} \\ J_{\eta,2\gamma_{2}(k,N_{r}+1)+2,2\gamma_{2}(k,N_{r}+1)+1} & J_{\eta,2\gamma_{2}(k,N_{r}+1)+2,2\gamma_{2}(k,N_{r}+1)+2} \end{bmatrix}.$$

B. CRLB of τ_{k,n_r} and α_{k,n_r}

To calculate this, let us define

$$\boldsymbol{\beta} = [\tau_{1,1}, \alpha_{1,1}, g_{1,1}, f_{d,1,1}, \dots, \tau_{1,N_{r}}, \alpha_{1,N_{r}}, g_{1,N_{r}}, f_{d,1,N_{r}}, \dots, \tau_{K,1}, \alpha_{K,1}, g_{K,1}, f_{d,K,1}, \dots, \tau_{K,N_{r}}, \alpha_{K,N_{r}}, g_{K,N_{r}}, f_{d,K,N_{r}}].$$

The $(i, j)^{\text{th}}$ component of $\mathbf{I}_{\boldsymbol{\beta}}$, the information matrix of vector $\boldsymbol{\beta}$, is equal to $\left[\mathbf{I}_{\boldsymbol{\beta}}\right]_{i,j} = \mathcal{R}\left\{ \begin{bmatrix} \frac{\partial \mathbf{f}}{\partial \beta_i} \end{bmatrix}^H \mathbf{Q}_{\mathbf{z}} \begin{bmatrix} \frac{\partial \mathbf{f}}{\partial \beta_j} \end{bmatrix} \right\}$. For $k \in \mathcal{K}$, and $n_{\mathbf{r}} \in \mathcal{N}_{\mathbf{r}}$, the elements of the derivative of vector \mathbf{f} with respect to β_i for $i = 4\gamma_2(k, N_{\mathbf{r}}) + 4n_{\mathbf{r}} - 3$ are as

$$\begin{bmatrix} \frac{\partial \mathbf{f}}{\partial \beta_{4\gamma_2(k,N_{\mathrm{r}})+4n_{\mathrm{r}}-3}} \end{bmatrix}_{\gamma_1(n,\bar{t},n_{\mathrm{r}})} = (24)$$

$$\sqrt{E_s}g_{k,n_{\mathrm{r}}}(j2\pi(n-1)\Delta f)\sum_{m=1}^M \left[\mathbf{\Phi}_k(\bar{t})\right]_{m,m}\mu(n,k,n_{\mathrm{r}},m).$$

Moreover, the elements of $\frac{\partial \mathbf{f}}{\partial \beta_i}$ for $i = 4\gamma_2(k, N_r) + 4n_r - 2$ are equal to

$$\left[\frac{\partial \mathbf{f}}{\partial \beta_{4\gamma_2(k,N_{\mathrm{r}})+4n_{\mathrm{r}}-2}}\right]_{\gamma_1(n,\bar{t},n_{\mathrm{r}})} = (25)$$

$$j\frac{2\pi}{\lambda}d\sqrt{E_s}g_{k,n_{\mathrm{r}}}\sum_{m=1}^M (m-1)\left[\mathbf{\Phi}_k(\bar{t})\right]_{m,m}\mu(n,k,n_{\mathrm{r}},m),$$

and for $i = 4\gamma_2(k, N_r) + 4n_r - 1$ and $i = 4\gamma_2(k, N_r) + 4n_r$ are given by (26) and (27), respectively.

$$\left[\frac{\partial \mathbf{f}}{\partial \beta_{4\gamma_2(k,N_{\mathrm{r}})+4n_{\mathrm{r}}-1}}\right]_{\gamma_1(n,\bar{t},n_{\mathrm{r}})} \sum_{m=1}^M [\mathbf{\Phi}_k(\bar{t})]_{m,m} \,\mu(n,k,n_{\mathrm{r}},m),\tag{26}$$

$$\left[\frac{\partial \mathbf{f}}{\partial \beta_{4\gamma_2(k,N_{\mathrm{r}})+4n_{\mathrm{r}}}}\right]_{\gamma_1(n,\bar{t},n_{\mathrm{r}})} = (27)$$

$$\sqrt{E_s}g_{k,n_{\mathrm{r}}}(j2\pi T_{\mathrm{d}}(\bar{t}-1))\sum_{m=1}^M \left[\mathbf{\Phi}_k(\bar{t})\right]_{m,m}\mu(n,k,n_{\mathrm{r}},m).$$

The CRLBs of τ_{k,n_r} and α_{k,n_r} are respectively equal to $[\mathbf{J}_{\boldsymbol{\beta}}]_{4\gamma_2(k,N_r)+4n_r-3,4\gamma_2(k,N_r)+4n_r-3}$ and $[\mathbf{J}_{\boldsymbol{\beta}}]_{4\gamma_2(k,N_r)+4n_r-2,4\gamma_2(k,N_r)+4n_r-2}$ in which $\mathbf{J}_{\boldsymbol{\beta}} = \mathbf{I}_{\boldsymbol{\beta}}^{-1}$.

$$\left[\frac{\partial \mathbf{f}}{\partial \eta_{2\gamma_2(k,N_{\mathrm{r}}+1)+i'}}\right]_{\gamma_1(n,\bar{t},n_{\mathrm{r}})} = \sqrt{E_s} g_{k,n_{\mathrm{r}}} \sum_{m=1}^M \left[\mathbf{\Phi}_k(\bar{t})\right]_{m,m} \mu(n,k,n_{\mathrm{r}},m) \left(j2\pi(n-1)\Delta f \frac{\partial \tau_{k,n_{\mathrm{r}}}}{\partial p_{k,i'}} + j\frac{2\pi}{\lambda}(m-1)d\frac{\partial \alpha_{k,n_{\mathrm{r}}}}{\partial p_{k,i'}}\right), \ i' = 1,2.$$

$$(21)$$

VI. SIMULATION RESULTS

In this Section, we provide the simulation results to demonstrate the performance of the proposed localization and tracking approaches. We consider a Tx located at $\mathbf{p}_{t} = [0,0]$ and three Rxs located at $\mathbf{p}_{r,1} = [12,0]$, $\mathbf{p}_{r,2} = [14,0]$ and $\mathbf{p}_{r,3} = [16,0]$, respectively. In each simulation two RISs are considered such that the location of one of them is as explained in the caption of the figures, while the location of the other RIS is random and the results are averaged on this location. The other simulation settings are as shown in Table II. In the following, we present the simulations of the localization and tracking approaches, each in an individual subsection. For the localization performance we use the approach of [31] as a benchmark. To have a fair comparison, our proposed phase shift design approach is used for both the localization approaches and the number of the transmissions are the same.

A. Localization Performance

In this Section, we investigate the performance of the proposed localization approach.

Fig. 8. PEB (dB) of RIS localization using the Tx and Rxs.

TABLE II							
SIMULATION PARAMETERS							
Parameter	Value						
Carrier Frequency (f_c)	6GHz						
RIS element spacing (d)	$\lambda/4$						
Total Transmit power (NE_s)	30dBm						
Number of subcarriers (N)	512						
Subcarrier bandwidth (Δ_f)	120 kHz						
T	32						
NT	2						
FFT dimensions $(N_{f,\tau})$	8192						
FFT dimensions (N_{f,f_d})	1024						
The angle of orientation of the RIS (ψ_{k,n_r})	$\pi/6$						
N ₀	-174 dBm/Hz						

1) Effect of Number of Rxs: We explore the effect of the number of Rxs on the performance of the proposed localization approach as depicted in Fig. 3. In this figure, we compare the localization error of the systems with three, five, and nine Rxs in terms of Δ_f , N and total transmit power. As expected, we observe that increasing the number of Rxs enhances the localization accuracy. Obviously, this improvement is resulted by leveraging a larger set of measurements made available by larger number of Rxs.

2) Effect of Parameters N_T and T: In Fig. 4, we verify the impact of the parameters N_T and T on the localization error of the proposed approach and PEB. In Fig. 4(a), we observe that increasing the number of transmissions by increasing N_T reduces the error of the localization approach as well as the value of PEB. It is noticeable that increasing N_T actually improves the accuracy of the estimation of α_k (see (11)). In Fig. 4(b), we notice that increasing T also improves the accuracy of the localization approach and the PEB, which is

Fig. 9. Investigation of tracking accuracy over path 1 (a): For different values of the transmit power. (b): For different values of T (c): Tracking error over the path. $\|\mathbf{v}[0]\| = 10m/s$, $\|\mathbf{a}\| = 2m/s^2$.

due to the effect of increasing T on the variance of the noise of the observation vector. However, we must note that enhancing the performance of the localization approach by increasing values of N_T and T will be at the cost of increasing the delay and power consumption for localization. Also, it is notable that the discrepancy between the PEB and the localization error stems from the fact that the CRLB does not consider the available resolution and cares more about the accuracy relying the assumption that the problem is resolvable. However, in the proposed localization approach we utilize the FFT method as a practical estimator for the ToA and the Doppler shift, which is constrained by the resolution of the FFT operation, which depends on the bandwidth.

Fig. 10. Average of the CDFs of error over path 1 for different variances of initial localization error. $\|\mathbf{v}[0]\| = 10m/s$, $\|\mathbf{a}\| = 2m/s^2$. The values of the average error over the path for $\sigma_0 = 0$, $\sigma_0 = 0.05$ and $\sigma_0 = 0.2$ are equal to 8.48×10^{-4} , 4.38×10^{-2} and 0.18, respectively.

3) Effect of Parameters Δ_f , N and Total Transmit Power: In Fig. 5, we investigate the effect of subcarrier bandwidth (Δ_f) , number of subcarriers (N) and total transmit power on the performance of the proposed localization approach and compare the results with [31]. In Fig. 5(a), we illustrate the localization error in terms of Δ_f for different values of N. We observe that increasing the subcarrier bandwidth, enhances the accuracy of both the localization approaches. Indeed, by increasing the value of Δ_f the accuracy of ToAs estimation is improved, leading to better localization results. Also, we can note that the proposed approach has significantly enhanced the localization accuracy in comparison with [31]. Specifically, in this case, our approach achieves the same localization accuracy, but at a half number of subcarriers. In Fig. 5(b), we plot the localization error in terms of N. We observe that increasing the number of subcarriers leads to a reduction in the localization error for both the proposed approaches. We can note that in the case of the proposed localization approach, increasing the number of subcarriers actually enhances the estimation of α_{k,n_r} as well as the estimation of τ_{k,n_r} (see (8) and Algorithm 1). In Fig.5(c), we depict the localization error in terms of total transmit power for different subcarrier bandwidths. We observe that as expected, increasing the transmit power reduces the error of both the localization approaches due to the improvement of the signal-to-noise ratio (SNR) of the received signals. Moreover, for a localization accuracy of 0.1m, our proposed localization approach reduces the transmit power roughly by 20%.

In Fig. 6, we investigate the effect of Δ_f and N as the total bandwidth is fixed. We depict the localization error in terms of Δ_f and N, for different bandwidth values BW= 256×120 kHz and BW= 512×120 kHz. We observe that for both the localization approaches, there is a optimal value for Δ_f and N.

4) Effect of the Position of the RIS: To further investigate the performance of the proposed approach, in Fig. 7, we examine its performance in terms of the x-coordinate and ycoordinate of the RIS location. In Fig. 7(a), it is evident that as the distance between the RIS and the line between the Tx and Rx increases, the superiority of the proposed approach

Fig. 11. Investigation of tracking accuracy, (a): Tracked paths. (b): Average CDF of the error of the proposed tracking and localization approach over the paths. For paths 1 and 2 ||v[0]|| = 10m/s, for paths 3 and 4 ||v[0]|| = 20m/s, and for all paths $||\mathbf{a}|| = 2m/s^2$. The values of the average error of the tracking approach over the paths are equal to 0.14, 0.26, 0.16 and 0.43, respectively. Also, the values of the average error of the localization approach over the paths are equal to 0.21, 0.32, 0.42 and 0.66, respectively.

over [31] becomes more pronounced. Also, Fig. 7(b) shows the improvement of the accuracy by the proposed approach for different values of x. The behaviour of the curves in terms of xand y can be attributed to the PEB of the localization in various points of the region. In this regard, we plot the heat map of the PEB in Fig. 8. We observe that as the distance between the RIS and the line between the Tx and Rx increases, the PEB tends to increase. Moreover, the minimum PEB occurs near the Rxs, while near the Tx the error is higher.

B. Tracking Performance

Now, we investigate the performance of the proposed tracking approach. In this regard, we examine the tracking of path 1 in Fig. 9. In Fig. 9(a) and Fig. 9(b), we plot the tracked path using different values of T and transmit power, and also using the proposed localization approach. We observe that both increasing T and the transmit power could improve the accuracy of the tracking approach. Also, comparing the tracking and localization approach we can observe that in most points the accuracy of the tracking approach is higher. Moreover, the benefit of the tracking approach compared to the localization is that in tracking the error at each point is less compared to the previous points. In Fig. 9(c), we illustrate the error of the tracking approach over path 1. We observe that as expected, for different values of T and transmit power the tracking approach reduces the error of the localization over the time.

In Fig. 10, we investigate the effect of the initial localization error on the error of tracking over the path. In this Fig., we illustrate the average CDF of the error over the path for different values of standard deviation of the initial localization error and also obtain the average error over the path. We observe that as expected the accuracy of the tracking error is affected by the variance of the initial error, but for each variance the tracking error reduces the average error compared to the error of the initial point.

To further investigate the performance of the tracking approach, in Fig. 11, we examine the tracking approach for two different initial velocities, and also compare the accuracy of the tracking over each path with accuracy of the localization approach. The initial velocity of the RIS on paths 1 and 2 is 10m/s, while its initial velocity on paths 3 and 4 is 20m/s. In Fig. 11(a), we observe that in all the cases the tracking approach compensates the initial error along the path. In Fig. 11(b), we compare the average CDFs of the error of the tracking and the localization approaches over the paths. We observe that on average over each path the tracking approach could increase the probability of having less error, for different values of *e*, compared to the localization approach.

VII. CONCLUSION

In this paper, we investigated the problem of tracking RISs employing a single antenna transmitter and multiple single antenna receivers. In this regard, we proposed a phase shift design approach to eliminate the effects of scatters and extract the signal passed through each RIS. Then, we proposed a localization approach to estimate the initial location of the RISs. The simulation results demonstrate that this approach outperforms the previously proposed ToA-based approach. Finally, based on the EKF approach we proposed a tracking algorithm. The simulation results confirm the accuracy of the proposed tracking approach.

APPENDIX A

In this appendix, we derive the partial derivatives of τ_{k,n_r} and α_{k,n_r} , and using them obtain the elements of matrix $\mathbf{H}_k[n|n-1]$. The partial derivative of τ_{k,n_r} with respect to $p_{k,i}$ for i = 1, 2 is equal to

$$\frac{\partial \tau_{k,n_{\mathrm{r}}}}{\partial p_{k,i}} = \frac{p_{k,i} - p_{\mathrm{t},i}}{c \left\|\mathbf{p}_{k} - \mathbf{p}_{\mathrm{t}}\right\|} + \frac{p_{k,i} - p_{\mathrm{r},n_{\mathrm{r}},i}}{c \left\|\mathbf{p}_{k} - \mathbf{p}_{\mathrm{r},n_{\mathrm{r}}}\right\|}, \ i = 1, 2, \quad (28)$$

$$\begin{aligned} \left[\mathbf{H}_{k}[n|n-1]\right]_{N_{r}+n_{r},1} &= \cos\psi_{k,n_{r}} \Big(\frac{(p_{k,1}[n|n-1]-p_{t,1}] \|\mathbf{p}_{k}[n|n-1]-\mathbf{p}_{t,1}]}{|p_{k}[n|n-1]-\mathbf{p}_{t,1}| \|\mathbf{p}_{k}[n|n-1]-\mathbf{p}_{t,1}|} - \frac{(p_{k,1}[n|n-1]-p_{t,1}] |p_{k,1}[n|n-1]-\mathbf{p}_{t,1}|}{||\mathbf{p}_{k}[n|n-1]-\mathbf{p}_{r,n_{r},1}|} + \frac{(p_{k,1}[n|n-1]-p_{r,n_{r},1}) |p_{k,1}[n|n-1]-p_{r,n_{r},1}|}{||\mathbf{p}_{k}[n|n-1]-\mathbf{p}_{r,n_{r},1}|} \Big) + \\ &= \frac{(p_{k,1}[n|n-1]-p_{r,n_{r},1}] \|\mathbf{p}_{k}[n|n-1]-\mathbf{p}_{r,n_{r},1}|}{||\mathbf{p}_{k}[n|n-1]-\mathbf{p}_{t,1}|} + \frac{(p_{k,1}[n|n-1]-p_{r,n_{r},1}) |p_{k,1}[n|n-1]-p_{r,n_{r},1}|}{||\mathbf{p}_{k}[n|n-1]-\mathbf{p}_{r,n_{r},1}|} \Big) + \\ &= \sin\psi_{k,n_{r}} \Big(-\frac{|p_{k,2}[n|n-1]-p_{t,2}| (p_{k,1}[n|n-1]-p_{t,1})}{||\mathbf{p}_{k}[n|n-1]-\mathbf{p}_{t,1}|} - \frac{(p_{k,2}[n|n-1]-p_{r,n_{r},2}] (p_{k,1}[n|n-1]-p_{r,n_{r},1})}{||\mathbf{p}_{k}[n|n-1]-\mathbf{p}_{t,1}|} \Big) \Big) \\ &= \frac{|p_{k,1}[n|n-1]-p_{r,n_{r},1}| (p_{k,2}[n|n-1]-p_{r,n_{r},2})}{||\mathbf{p}_{k}[n|n-1]-\mathbf{p}_{r,n_{r},2}|} \Big) + \sin\psi_{k,n_{r}} \Big(\frac{(p_{k,2}[n|n-1]-p_{t,2})}{||p_{k,2}[n|n-1]-p_{t,2}| ||p_{k}[n|n-1]-\mathbf{p}_{t,n_{r},2}|} \\ &= \frac{(p_{k,2}[n|n-1]-p_{t,2}] |p_{k,2}[n|n-1]-p_{t,2}|}{||\mathbf{p}_{k}[n|n-1]-\mathbf{p}_{t,n_{r},2}|} \Big) + \frac{(p_{k,2}[n|n-1]-p_{r,n_{r},2}] ||p_{k}[n|n-1]-\mathbf{p}_{t,n_{r},n_{r}}||^{3}}{|p_{k,2}[n|n-1]-p_{r,n_{r},2}| ||p_{k,2}[n|n-1]-p_{r,n_{r},2}|} \Big) \Big). \end{aligned}$$
(35)

and the partial derivatives of α_{k,n_r} with respect to $p_{k,1}$ and $p_{k,2}$ are respectively given as

$$\frac{\partial \alpha_{k,n_{r}}}{\partial p_{k,1}} = \cos \psi_{k,n_{r}} \left(\frac{(p_{k,1} - p_{t,1})}{|p_{k,1} - p_{t,1}| ||\mathbf{p}_{k} - \mathbf{p}_{t}||} - \frac{(p_{k,1} - p_{t,1}) |p_{k,1} - p_{t,1}|}{||\mathbf{p}_{k} - \mathbf{p}_{t}||^{3}} - \frac{(p_{k,1} - p_{r,n_{r},1})}{|p_{k,1} - p_{r,n_{r},1}| ||\mathbf{p}_{k} - \mathbf{p}_{r,n_{r}}||} + \frac{(p_{k,1} - p_{r,n_{r},1}) |p_{k,1} - p_{r,n_{r},1}|}{||\mathbf{p}_{k} - \mathbf{p}_{r,n_{r}}||^{3}} \right) + \sin \psi_{k,n_{r}} \left(\frac{(p_{k,2} - p_{t,2})}{|p_{k,2} - p_{t,2}| ||\mathbf{p}_{k} - \mathbf{p}_{t}||} - \frac{(p_{k,2} - p_{r,n_{r},2}) |p_{k,2} - p_{r,n_{r},2}|}{||\mathbf{p}_{k} - \mathbf{p}_{r,n_{r}}||} - \frac{(p_{k,2} - p_{r,n_{r},2}) |p_{k,2} - p_{r,n_{r},2}|}{||\mathbf{p}_{k} - \mathbf{p}_{r,n_{r}}||} \right),$$
(29)

and

$$\frac{\partial \alpha_{k,n_{\rm r}}}{\partial p_{k,2}} = -\frac{|p_{k,2} - p_{\rm t,2}| (p_{k,1} - p_{\rm t,1})}{\|\mathbf{p}_{k} - \mathbf{p}_{\rm t}\|^{3}} - \frac{|p_{k,2} - p_{\rm r,n_{r},2}| (p_{k,1} - p_{\rm r,n_{r},1})}{\|\mathbf{p}_{k} - \mathbf{p}_{\rm r,n_{r}}\|^{3}}.$$
(30)

Thus, considering (19), the elements (n_r, i) of $\mathbf{H}_k[n|n-1]$ for $n_{\mathrm{r}} \in \mathcal{N}_{\mathrm{r}}$ and $i = 1, \ldots, 4$ would be as follows

$$[\mathbf{H}_{k}[n|n-1]]_{n_{\mathrm{r}},1} = \frac{p_{k,1}[n|n-1] - p_{\mathrm{t},1}}{\|\mathbf{p}_{k}[n|n-1] - \mathbf{p}_{\mathrm{t}}\|}$$
(31)

$$+ \frac{p_{k,1}[n|n-1] - p_{\mathbf{r},n_r,1}}{\left\|\mathbf{p}_{k}[n|n-1] - \mathbf{p}_{\mathbf{r},n_r}\right\|},$$

$$[\mathbf{H}_{k}[n|n-1]]_{n_{r},2} = \frac{p_{k,2}[n|n-1] - p_{t,2}}{\|\mathbf{p}_{k}[n|n-1] - \mathbf{p}_{t}\|}$$
(32)
+
$$\frac{p_{k,2}[n|n-1] - p_{r,n_{r},2}}{\|\mathbf{p}_{k}[n|n-1] - \mathbf{p}_{r,n_{r}}\|},$$

$$\begin{aligned} [\mathbf{H}_{k}[n|n-1]]_{n_{r},3} &= T_{s} \frac{p_{k,1}[n|n-1] - p_{t,1}}{\|\mathbf{p}_{k}[n|n-1] - \mathbf{p}_{t}\|} \quad (33) \\ &+ T_{s} \frac{p_{k,1}[n|n-1] - p_{r,n_{r},1}}{\|\mathbf{p}_{k}[n|n-1] - \mathbf{p}_{r,n_{r}}\|}, \\ [\mathbf{H}_{k}[n|n-1]]_{n_{r},4} &= T_{s} \frac{p_{k,2}[n|n-1] - p_{t,2}}{\|\mathbf{p}_{k}[n|n-1] - \mathbf{p}_{t}\|} \quad (34) \\ &+ T_{s} \frac{p_{k,2}[n|n-1] - p_{r,n_{r},2}}{\|\mathbf{p}_{k}[n|n-1] - \mathbf{p}_{r,n_{r}}\|}. \end{aligned}$$

11

Additionally, the elements $(n_{\rm r}+N_{\rm r},i)$ of $\mathbf{H}_k[n|n-1]$ for $n_{\rm r} \in \mathcal{N}_{\rm r}$ and $i = 1, \ldots, 4$ are as (35), (36), (37) and (38).

$$[\mathbf{H}_{k}[n|n-1]]_{N_{r}+n_{r},3} = T_{s}[\mathbf{H}_{k}[n|n-1]]_{N_{r}+n_{r},1}.$$
(37)
$$[\mathbf{H}_{k}[n|n-1]]_{N_{r}+n_{r},4} = T_{s}[\mathbf{H}_{k}[n|n-1]]_{N_{r}+n_{r},2}.$$
(38)

$$\mathbf{H}_{k}[n|n-1]]_{N_{r}+n_{r},4} = \mathbf{I}_{s}[\mathbf{H}_{k}[n|n-1]]_{N_{r}+n_{r},2}.$$

Somayeh Aghashahi (S'16) received the B.Sc. degree in pure mathematics from Shahid Bahonar University of Kerman, Kerman, Iran, in 2013, and received the M.Sc. degree in communication systems engineering from Yazd Unversity, Yazd, Iran, in 2018, where she is currently pursuing the Ph.D degree in communication systems engineering. Her research interests include wireless communication and statistical signal processing with a particular emphasis on MIMO communications, RIS and reconfigurable antennas assisted communication and

localization.

Zolfa Zeinalpour-Yazdi received the B.S., M.S., and Ph.D. degrees in electrical engineering from the Sharif University of Technology, Tehran, Iran, in 2002, 2004, and 2010, respectively. She was a Visiting Researcher with ftw. Telecommunication Research Center, Vienna, Austria, in 2006. She joined Yazd University in 2010, where she is currently an Associate Professor with the Department of Electrical Engineering. Her research interest includes the broad area of wireless communications and currently, she is working towards next gener-

ation of wireless networks and mathematical treatment of the problems in these areas with a particular emphasis on stochastic analysis of heterogeneous networks, vehicular communications, RIS-empowered transmissions and also interference management and caching strategy in these networks.

Ahmed Elzanaty (S'13-M'18-SM'22) received his PhD degree (cum laude) in electronics, telecommunications, and information technology from the University of Bologna, Italy, in 2018. Currently, he is a Lecturer (Assistant Professor) with the Institute for Communication Systems, University of Surrey, U.K. Before that, he was a Postdoctoral Fellow at the King Abdullah University of Science and Technology (KAUST), Saudi Arabia. He has participated in several national and European projects, such as TUDOR, CHEDDAR, and EuroCPS. His

research interests include the design and performance analysis of wireless communications and localization systems.

Aliakbar Tadaion (S' 05-M' 07-SM' 13) was born in Iran in 1976. He received the B.Sc. degree in electronics, the M.Sc. and Ph.D. degrees in communication systems all from Sharif University of Technology, Tehran, Iran, in 1998, 2000 and 2006, respectively. From August 2004 to June 2005, he was with the Department of Electrical and Computer Engineering, Queen's University, Kingston, ON, Canada, as the visiting researcher. He joined the department of electrical Engineering, Yazd University, Yazd, Iran in Sep. 2005, where he is now a

Professor. He is also the founder and director of Cell Lab. Now he is a senior member of the Institute of Electrical and Electronics Engineers (IEEE) and also since Jan. 2013, he has been a member of the excom committee of IEEE Iran Section and the newsletter editor of the Iran Section. He has been the technical program committee member of some conferences, such as WOSSPA 2011, IWCIT 2013-2024 and has served as an organizing committee member of some conferences such as ISCC 2012.

Mahdi Boloursaz Mashhadi (S'15-M'19-SM'23) is a Lecturer at the 5G/6G Innovation Centre (5G/6GIC) at the Institute for Communication Systems (ICS), University of Surrey (UoS), and a Surrey AI fellow. His research is focused at the intersection of AI/ML with wireless communication, learning and communication co-design, generative AI for telecommunications, and collaborative machine learning. He received B.S., M.S., and Ph.D. degrees in mobile telecommunications from the Sharif University of Technology (SUT), Tehran, Iran. He has

more than 40 peer reviewed publications and patents in the areas of wireless communications, machine learning, and signal processing. He is a PI/Co-PI for various government and industry funded projects including the UKTIN/DSIT 12M£ national project TUDOR. He received the Best Paper Award from the IEEE EWDTS conference, and the Exemplary Reviewer Award from the IEEE ComSoc in 2021 and 2022. He served as a panel judge for the International Telecommunication Union (ITU) on the "AI/ML in 5G" challenge 2021-2022. He is an associate editor for the Springer Nature Wireless Personal Communications Journal.
