Abstract

Organizations worldwide that rely on data-driven approaches regularly employ forecasting methods to enhance their planning and decision-making processes. While extensive research has examined the harms associated with traditional machine learning applications, relatively little attention has been given to the ethical implications of time series forecasting. However, forecasting presents distinct ethical challenges due to its diverse organizational applications, varied objectives, and unique data processing, model development, and evaluation workflows. These distinctions complicate the direct application of existing machine learning harm taxonomies to common forecasting scenarios. To address this gap, we conduct multiple interviews with industry experts and academic researchers, systematically identifying and analyzing under-explored domains, use cases, and potential risks associated with forecasting. Our objective is to develop a novel taxonomy of forecasting-specific harms. Drawing inspiration from Microsoft Azure's taxonomy for responsible innovation, we integrate a human-led inductive coding approach with AI-driven analysis to extract key categories of harm in forecasting. This taxonomy aims to support researchers and practitioners by fostering ethical reflection on their decision-making throughout the forecasting process. Additionally, we seek to establish a research agenda focused on identifying measures to mitigate potential harms in forecasting. By highlighting unique risks within forecasting, our work contributes to the broader discourse on machine learning ethics.

Keywords: forecasting, harm, models, algorithms, ethics, data science

1 Introduction

Time series forecasting is, broadly, the process of using historical data points collected sequentially over time to predict future values. Modern forecasting techniques enable organizations to more effectively plan, manage risk and deal with uncertainty by estimating likely future outcomes. Forecasting models allow organizations to avoid problems that may arise by simply repeating previously successful actions from the recent past, imitating the actions of successful peers, or else following their leaders' often-questionable "gut instincts".

Despite the pervasive use and benefits of forecasting in business and society, we know surprisingly little about the harms specific to forecasting. Even popular textbooks on forecasting (Montgomery et al. 2015, Hyndman &

Athanasopoulos 2021) do not substantively engage with the issue of harm¹ or discuss responsible forecasting practices. Very little work exists on these topics, yet in our experience most forecasters see value in being more transparent about its potential harms on individuals and society. This apparent tension piqued our curiosity.

Indeed, our interest in the topic of forecasting harm gradually emerged from candid discussions with forecasting experts in both industry and academia. Forecasters frequently lamented the lack of awareness and the need for a structured analysis of forecasting's potential harm. For instance, the Editor-in-Chief of Foresight at the International Institute of Forecasters described the topic of forecasting harm as an "unexplored area," stating, "I hadn't heard this question posed like this before, but just bringing awareness makes a difference." He emphasized that identifying common ways forecasting introduces harm could itself help mitigate negative effects. Further insights emerged from a panel on ethical considerations in forecasting organised by the lead author, featuring experts from the International Organization for Migration, UNHCR Innovation, the Neukom Institute for Computational Science, and Yale University. Panellists discussed forecasting's unintended harms in migration, refugee crises, and public health, emphasizing the need for research and guidelines to mitigate negative consequences. They underscored how forecasting errors can have real-world impacts, affecting vulnerable populations and leading to resource misallocation. Industry case studies further reinforced these concerns around the social impact of forecasting-a Google data scientist highlighted how flawed forecasts contributed to Target Canada's collapse, resulting in a \$2.1 billion loss and the closure of 133 stores. Similar concerns were echoed in our interviews of 21 experts from academia and industry. One respondent noted, "I've seen people so fascinated by producing forecasts that they don't necessarily think about where it will be used, either well or poorly, for good or for harm" (P21). Another participant emphasized the importance of creating awareness: "Rather than accepting a set of signals, we should pause and think about how we consume this information" (P18). Overall, our discussions with forecasting experts in industry and academic shaped our research agenda by highlighting a few key gaps: the lack of a systematic treatment of forecasting harms, the tangible consequences of using forecasts across domains, and the need for ethical guidelines to mitigate the risks of harm.

What might explain these gaps in our understanding of forecasting harms? We offer several tentative hypotheses. First, forecasting often takes place behind closed doors, making it difficult for researchers external to an organization to study. Second, forecasting—in contrast to traditional supervised learning with cross-sectional data—generally focuses on predicting the behavior of aggregates rather than individual units, making it hard to identify harms to specific individuals or organizations. When harms to individuals are thinly spread out over society, no one single person is motivated enough to speak out. Also, the focus on aggregates also means that personal data generally plays a smaller role in forecasting, which may contribute to less legal and regulatory scrutiny. Third, unlike some applications of AI and machine learning that have provoked major media and journalism reporting (e.g., social credit scoring, facial recognition, and criminal risk predictions), applications of forecasting have tended to receive much less popular coverage. This last reason is perhaps again because much information about forecasting stays within organizations, making it difficult for an external individual or group to contest the quality or accuracy of a forecast.

Three objectives therefore motivate this study. 1) *What are the harms specific to forecasting*?; 2) *How might such harms be mitigated*? and 3) *What should a research agenda for responsible forecasting entail*? Answers to these questions lead to a taxonomy of forecasting-specific harms, and a practical toolbox of harm mitigation strategies. Ultimately, we hope our research can contribute to understanding and awareness about where and how forecasts can be used for good, and promote ethical reflection and critical discussion on the role of forecasters in society.

¹The single mention of "harm" we found comes from the 600-plus-page textbook Montgomery et al. (2015, pg. 21), who asks the reader to discuss "the harm or penalty associated with a bad forecast" as a homework exercise.

Note that for the purpose of this study we distinguish forecasting from other similar terms, such as "predictive AI" or "predictive analytics,"² using the following heuristic criteria: 1) forecasting is forward-looking, providing estimations of the variable of interest's value at one or more future time periods; 2) forecasting is based on historical observations of the variable of interest (i.e., time series); and 3) the forecasting models can include past and future values of other exogenous variables (Hewamalage et al. 2021, Makridakis et al. 2020).

This paper is structured as follows. Section 2 briefly surveys relevant legal and philosophical literature to examine the concept of harm with the goal of relating these considerations to issues in forecasting. Section 3 explains our methodology based on a combination of inductive coding and AI-assisted categorization. Our results and typology are in Section 4. Section 5 discusses our results, and Section 6 proposes future research directions for the ethics of responsible forecasting. We conclude with a summary of our findings and some final comments in Section 7.

2 Harms in forecasting

2.1 The concept of harm

Recognizing a forecasting harm requires a theory of harm to guide questions of moral and legal responsibility for harms. Yet, as with many concepts that have ethical and political implications, the concept of harm is interrelated with contested notions of *wrongs, justice, duties, rights, responsibility, interests, intentions, causality, care, liability,* and *consent,* to name just a few (Feinberg 1984). This makes it hard to define harm without begging the question. Our goal is not to articulate a novel theory of harm specific to forecasting, but to leverage the pre-existing harm-related concepts and frameworks developed and refined by legal scholars, philosophers, and (increasingly) AI ethics researchers.

Nearly all human cultures have subscribed to some version of the idea that we should, where reasonable, avoid doing harm to others (Bradley 2012). The prohibition on harm is so important that it is presumed to also apply to intelligent machines created by humans. For instance, the first of Isaac Asimov's influential "three laws of intelligent machines" begins with the command: "A robot may not injure a human being, or, through inaction, allow a human being to come to harm" (Asimov 1978). So while there is nearly universal consensus that intelligent machines should avoid inflicting harm on humans, a more difficult question is what constitutes a harm. Here we turn to fields that specialize in examining definitional questions: philosophy and law.

Philosophical and legal accounts generally focus on three senses of harm: 1) something being damaged or broken; 2) unjust or wrongful treatment; and 3) the "defeating of an interest" (Feinberg 1984, pg. 33). In this initial study, we treat the concept of harm as a cluster concept, and provisionally define harm as *unjustly or wrongly setting back an interest of an individual or collective of individuals* (e.g., an organization).³ Future research might explore how to best define the normative terms "unjust" or "wrong" in the context of forecasting.

²In practice many of the same statistical forecasting methods are used atemporally to, for instance, classify objects, estimate past numeric values, or retrieve information (Barocas et al. 2023).

³It is worth noting—especially since the AI ethics literature often invokes human rights (Aizenberg & Van Den Hoven 2020)—that rights function as legal devices to protect an entity's interests and imply (sometimes burdensome) correlative duties on others (O'Neill 2002). Legal documents that draw on fundamental rights, such as the EU's GDPR, commonly rely on "balancing tests" to consider how the exercise of a data subject's right justifies imposing a correlative duty on another entity (i.e., an organization wishing to process such data for business reasons) (Greene et al. 2019).

2.2 Typologies of AI harms

Diverse communities of researchers with interests in "AI for social good" (Floridi et al. 2021) and Fairness, Accountability, Transparency, and Ethics (FATE) in machine learning (Wieringa 2020), have singled out a number of harms stemming from the use of supervised, unsupervised and reinforcement learning algorithms. These harms include the maintenance of historically unjust power relations, the generation of toxic language, the promotion of addictive behaviors, and the fostering of various informational harms related to, for instance, the spread of polarizing news or conspiratorial beliefs in society (Chan et al. 2023). AI ethics researchers have also begun to study the dynamics and harms of self-fulfilling prophecies when AI/ML models are applied in social contexts (King & Mertens 2023).

Technological harms can arise at multiple levels of society. Shelby et al. (2023) constructed a taxonomy of sociotechnical harms at micro-, meso- and macro-levels stemming from the use of algorithms. They thematically list the harms as representational harms, allocative harms, quality of service harms, interpersonal harms, and social system harms. Broadly, these harms relate to how social groups are represented in inputs and outputs, how these representations influence resource distribution decisions, how optimization choices relate to model performance for various users, how the model outputs affect social relations and properties of social systems, such as their level of stability or equality. Due to forecasting's traditional focus on aggregate behavior, allocative and social systems harms appear the most relevant to forecasting, while representational harms (i.e., the reinforcement of undesirable social and cultural stereotypes and beliefs) seem less relevant (see e.g., Barocas et al. (2017), Suresh & Guttag (2021)).

As with many new technologies that are rapidly introduced into society, newly identified harms can ignite streams of research. For instance, the rise of deep neural networks and large labeled image datasets such as ImageNet, stimulated a wave of research into how various morally-charged labels were associated with certain demographic groups (Denton et al. 2021). The rise of large language models (LLMs) has also led to a growing body of research focused on harms specific to LLMs. There are documented discrimination, exclusion and toxicity, and human-computer interaction harms, as well as automation, access, and environmental harms (Weidinger et al. 2022).

Industry researchers are the often the first to study the harms from new AI technologies. A white paper from Microsoft, which we refer to as the Microsoft Azure framework (Microsoft 2023), specifically addresses responsible innovation and technology harm mitigation strategies. The framework classifies technology harms into four types: risk of injury, denial of consequential services, infringement on human rights, and the erosion of social and democratic structures. *Risk of injury* refers to physical injury due to, for example, over-reliance on safety features, inadequate fail-safes, and exposure to unhealthy agents during technology manufacturing or disposal. It also covers emotional or psychological injury due to emotional distress, distortion of reality, reduced self-esteem, addiction, identity theft, and misattribution. *Denial of consequential services* reflects opportunity loss such as employment, housing, insurance, and educational discrimination, as well as digital divide and loss of choice. Technologies that automate decisions can lead to credit discrimination, differential pricing, economic exploitation, and devaluation of individual expertise. *Infringement of human rights* involves privacy, liberty, and dignity harms via dehumanization and changes in how people perceive and engage with each other in society. The *erosion of social and democratic structures* includes harms related to amplification of power inequality, behavioral manipulation and deception, and stereotype reinforcement.

2.3 From harms in AI to harms in forecasting

While research on responsible AI and machine learning is growing (Dignum 2019, Barocas et al. 2023), translating and applying these ideas and methods to forecasting pipelines is not straightforward. There is a pressing need for such work given the scale of forecasting's influence on human behavior and social systems. One notable exception

is Hobday et al. (2019), who examines ethical issues stemming from forecasting in the context of marine ecology, and proposes ten guiding principles for ethical forecasting. He recommends transparency, accurate uncertainty representation, stakeholder education, and performance reviews. These principles, although drawn from the specific domain of marine ecology, broadly align with the harm mitigation strategies we describe in Section 5.3.

The lack of more general work on forecasting harms is surprising for several reasons. First, many forecasting applications involve aspects of automated decision-making. For example, in retail and e-commerce, items are automatically ordered based on forecasted demand of "replenishables". AI and data protection regulations aimed at reducing the harms of "high risk" automated systems, usually subject automated systems to greater regulatory scrutiny than systems where humans are "in the loop" (Binns 2022). Second, forecasting can involve system-wide scales with catastrophic stakes, as when forecasting events such as financial crises, terrorist attacks, earthquakes, and floods (Sornette 2002). Third, societies around the world are witnessing rapid growth in the number of sensors and devices that capture and analyse individual-level time series data. Thus, forecasting has the potential to impact individuals, societies, and ecosystems as forecasts feed into increasingly complex automated decision-making systems.

These factors suggest the need for systematic study of the harms of forecasting and possible mitigation strategies aimed at promoting responsible forecasting practices. A better understanding of the harms of forecasting can lead to more socially aligned applications of forecasting (Thompson 2022). As one recent popular work on the ethics and politics of AI notes, "[the] separation of ethical questions away from the technical reflects a wider problem in the field, where the responsibility for harm is either not recognized or seen as beyond the scope of the research" (Crawford 2021). Related work in psychology and AI ethics also highlights how AI tools can inflate our "moral distance" to the needs and interests of others remote in time and space (Villegas-Galaviz & Martin 2023), contributing to an undesirable form of "moral disengagement" (Bandura 2002), and potentially blinding us to how our forecasting activities impact the interests and well-being of others. Our work attempts to address these gaps surrounding the ethics of forecasting by focusing on identifying various types of harm that may occur in the context of forecasting. The identification of harms can promote more reflexive and responsible forms of forecasting.

Lastly, a simplifying assumption guides our analysis of the forecasting process. We suppose that, regardless of sector or decision, the forecasting workflow is relatively stable across forecast types and applications. Thus, the typologies of harm and the mechanisms by which they may occur can be generalized, identified, and potentially mitigated when the workflow is described in a standardized way.

2.4 Harms of forecasting: preliminary ethical and legal considerations

The study of forecasting harm is still in its infancy. As a result, in many real-world cases where forecasts seem to cause harm, considerable disagreement pervades about who or what was harmed (and how), as well as who is responsible. To make progress on such important and practical issues, we suggest that an adequate theory of forecasting harm should provide reasonably clear answers to a basic set of questions. We therefore offer some preliminary theoretical desiderata, drawn from the fields of ethics and law. While not exhaustive, these initial desiderata can serve as normative benchmarks for the analysis and discussion of forecasting harms as understood by practising forecasters (Section 4). An overview of these theoretical considerations and relevant questions are given in Table 1.

Individual vs collective harms We presume that collectives such as human societies, and non-human collectives such as ecosystems, have interests that can be thwarted (see e.g., Taylor (1986)). We treat social and collective harms as synonyms, while noting some legal scholars argue that *societal harm* is conceptually distinct from individual and collective harm (Smuha 2021).

| Theory of harm desiderata | Description | Relevance to forecasting |
|---|--|--|
| Individual vs. Collective Harm | What kinds of entities have interests? | Do social and ecological systems have interests that can be unjustly defeated by forecasting? |
| Comparative vs. Absolute Harm | Must an account of harm consider how things could have gone? | What are the likely differences in potential harmful outcomes when publishing and not publishing a forecast? |
| Harm vs. Imposition of Risk | Must a harmful act result in observable consequences? | How should we think about poorly designed forecasting procedures that impose unjustifiable risk on society and individuals despite not realizing harmful consequences? |
| Intentions and Unforeseen Consequences | Does moral blame for harm depend on whether such harms were indirect or directly foreseen or intended? | To what extent can forecasters foresee an individual or collective reaction to the forecast? |
| Standards of Care and Negligence | To what extent is an activity inherently dangerous and risky, thereby imposing on participants a duty of care and liability for harm? | In what domains does forecasting constitute a dangerous or high-risk activity? What is the professional relation of forecasters to individuals and society? |

Table 1: Considerations for a theory of harm from law and philosophy, and their relevance to the harms of forecasts.

- *Comparative vs absolute harms* Comparative theories of harm draw on comparisons of actual well-being to counterfactual well-being had the event not occurred (Klocksiem 2012, Bradley 2012). In contrast, absolute harms do not take into account how things could have happened (but did not); they often involve causing an entity to enter an intrinsically bad state, such as pain, mental or physical discomfort, disease, deformity, disability, or even death (Harman 2009). Related to the idea of absolute harm is the view that the mere violation of a right (i.e., a protected interest) constitutes a harm (Feinberg 1984). Clarifying whether a claim of forecasting harm implicitly draws on a comparative or absolute theory of harm can help in determining whether, for instance, a group of individuals was truly harmed from the decision to publish a forecast.⁴
- *Harm vs imposition of risk* A further distinction relevant to forecasting is how and whether to separate harm from the imposition of risk. Distinguishing the two is not always simple, making an ethical analysis of forecasting complicated. This is because not all harms materialize (Finkelstein 2003), as when a drunk driver manages to safely drive home at night. Legal scholars and philosophers debate whether the imposition of risk is itself a harm (see e.g., Hayenhjelm & Wolff (2012)). To simplify our analysis, we treat them as interchangeable for now.

A related legal and philosophical concept is that of *moral luck* (Nagel 1979), which can arise when we blame an agent for some harm whose realization is stochastic in nature. Moral luck captures the intuition that moral judgments of agents can depend on factors outside of their control. For instance, although eventually most of the convictions were overturned on appeal, the scientists punished in the L'Aquila earthquake incident arguably

⁴The issue of euthanasia helps illustrate key differences between comparative and absolute theories of harm. In absolute accounts of harm, death is usually presumed to be a bad state, and so euthanasia constitutes a harm. But in the comparative account of harm, whether euthanasia is harmful depends on whether death is preferable to (otherwise) prolonged suffering. Under the comparative account of harm, depending on one's prognosis, euthanasia can receive a positive moral evaluation.

experienced moral (bad) luck, at least initially. The phenomenon of moral luck suggests a satisfactory theory of harm and punishment should not only consider actual outcomes, but also an agent's intent (Cane 2002).

Intentions and (un)foreseen consequences Ethical theories, particularly those drawing on Kantian or virtue-based conceptions of ethics, emphasize the motives and intentions of agents as relevant when evaluating responsibility for harm. Related to the issue of intent to harm is the foreseeability of harm. Consider a forecaster's ability to foresee how others may react to the disclosure of forecasts. Reactions to forecasts can themselves cause harm, sometimes systemic harms, as in bank runs whose effects can spell ruin for entire banking systems (Rochet 2009). Presumably, however, the forecaster does not intend to cause a bank run.

This example indicates an ethical analysis of harms related to forecasting may therefore distinguish between harms that are "actively" intended, from those merely "allowed" to happen indirectly as a byproduct of the disclosure. Here the *doctrine of double effect* (Foot 1967, Quinn 1989) seems relevant. The doctrine implies that forecasters are less morally responsible for the effects of their actions (i.e., disclosure) done knowingly but unintentionally.

Standards of care and negligence Civil or "tort" law concerns wrongs done by individuals to other individuals in society, often out of neglect (Cane 2002). Tort law concepts can clarify the nature of the relationship between forecasters and society, and help decide whether societal stakeholders are owed a duty of care. If this duty of care can be shown to have been breached, then forecasting organizations may be found liable for any resulting harm. But as the L'Aquila incident makes clear, causal responsibility for harm does not always imply legal or moral responsibility (Smiley 1992). Depending on the level of risk inherent to the activity, legal responsibility arises when persons and organizations fail to exercise due care while performing the activity. Setting standards of reasonable or "due" care encourages people and organizations to take appropriate precautions to avoid harming others, often at a cost. Legal systems seek to discern the appropriate—or just—balance between the reduction in harm and costs of precaution. Altogether, the issues of due care and negligence raise questions of the stakes of forecasting and what constitutes reasonable precaution when performing the activity of forecasting. Professionalization of forecasting, along the lines of medicine or law, could provide the institutional means of providing concrete answers to these harm-related questions, but likely at the cost of a reduction in forecasters' freedom.

3 Methods

3.1 Data collection and analysis techniques

In this paper, we used a combined inductive-deductive research approach. We began our investigation with a deductive analysis, focusing on the categories of harms defined in the previously-mentioned Microsoft Azure framework, along with the general theory of harm desiderata in Section 2, to identify, typify, and mitigate harms stemming from new technologies. We next expanded the research to identify the types of harm relevant to forecasting within the established categories. This hybrid approach enabled us to explore the details of forecasting-related harms, eventually leading to an inductive thematic analysis. One benefit of using Microsoft Azure framework is its capability to facilitate discussions on harm across various levels, ranging from individual and community to organizational, societal, and environmental dimensions.

We used a semi-structured interview method; the detailed interview protocol can be found in Appendix A. We used purposive sampling to ensure that we chose participants who could provide a wealth of information about the topic, prioritizing depth above mere numbers of interviews. We recruited people from academia and diverse

organizations who have extensive expertise and experience in forecasting. These "knowledgeable agents" came from a variety of disciplines, including supply chain, business, public health, healthcare operations, humanitarian and development operations, government bodies, and software development (see Appendix B). This diverse representation enabled a thorough investigation of forecasting interests across organizational types and sectors.

We conducted 21 interviews, each lasting 40 to 65 minutes, all of which were completed online for convenience and accessibility. This produced about 1121 minutes of interviews, resulting in a rich dataset for analysis. Due to space constraints, only a sample quote from the interviews is provided in the Appendix C. However, the full interview transcripts will be made accessible via a GitHub repository.

Ethical approval for this study was obtained from the Cardiff Business School Research Ethics Committee (Approval ID: 1727) on 19 June 2023. The study adhered to Cardiff University's ethical principles as outlined in the Policy on the Ethical Conduct of Research Involving Human Participants, Human Material, or Human Data. Informed consent was obtained from all participants, data were anonymized after data collection, and measures were implemented to ensure confidentiality and data security.

3.2 AI-assisted inductive coding method

Inspired by the Microsoft Azure framework's taxonomy for responsible innovation, we combined a human-led inductive coding scheme with an AI-driven analysis centered on the extraction of key themes of harms in forecasting. The AI-driven analysis utilized a LLM (Claude 2.1) to help identify categories of harm from the 21 interviews' transcripts. Before supplying Claude the transcripts, we provided it with the Microsoft Azure framework as an example of a harm typology. We then requested Claude to categorize the harms mentioned in the interviews into the Microsoft Azure framework categories, providing relevant quotes from the interviews. Finally, we requested Claude to create a new framework of forecasting harms, along with relevant quotes. In all cases, we carefully inspected each suggested harm category, and validated each quote from the interview transcript provided by the LLM. See Figure 1 for a schematic of the process of the steps in the AI-driven analysis. Table 2 shows the prompts used.

3.3 Human-led thematic analysis

In parallel, and independent from the AI-driven analysis of the interviews, the first author conducted a thematic analysis based on the topics and harm categories outlined in the Microsoft Azure framework and led the coding of the interview data, beginning with an analysis of the interview transcripts using NVivo 12, which is a commonly used software package for analyzing semi-structured interview data. Relevant quotes were assigned to each harm category, with existing themes being confirmed and potential new categories explored. The findings from the AI-driven analysis were then compared and consolidated with those from the human-led thematic analysis. This synthesis was used to inform both the findings and the discussion. For categories identified by both analyses, relevant quotes were collected, while new themes identified by the human analysis were highlighted. A table summarizing these findings can be accessed in the supplementary materials.

4 Findings: typology of harm in forecasting

This section captures the types of harm identified in the interviews. The analysis identified four main types of harm as illustrated in Figure 2: risk of injury, denial of consequential services, infringement on human rights, and erosion of social and democratic structures. In the following sections, we will highlight quotes from the interviews that illustrate

| Table 2: | Prompts | given to | Claude LLM |
|----------|---------|----------|------------|
|----------|---------|----------|------------|

| Action/Purpose | Prompt |
|--|---|
| Uploaded Microsoft Azure ta- ble (ManualTable.docx) | This is how different types of harm are assessed under the Microsoft Azure framework |
| Uploaded the document with 21 transcripts | This is a merged transcript file of 21 interviews. Each interview talks about the potential harms involved in forecasting. Without using the table, what examples do you consider harmful in this transcript for each interviewee? Please show me the quote and the definition of the harm you identified for all interviewees. |
| Match model response to Mi- crosoft Azure table | If you were to categorize this into the table I just uploaded, which "Topic" column would you put your response in? How confident are you towards each classification? Which of the harms do you identify that does not fit into the table? I would like you to include the definition and quote in each of your explanations as well. |
| Create forecast harm frame- work using the model | If we were to create a new framework for forecasting harms like Manu- alTable.docx, what are the themes, descriptions, and definition of the types of harms you would consider from all the interviewees' responses. I would also like you to specify the examples across all the interviewees that makes the type of harm presented relevant to this new framework. You do not need to use ManualTable.docx but it is provided to give you some ideas about the concept of harms. Remember to consider ALL the interviewees given in the transcript. |

each type of harm within these categories, stemming from inaccurate forecasts, poorly communicated forecasts, or simply publishing forecasts.

Figure 2: Types of harm in forecasting based on our interviews.

4.1 Risk of injury

This section explores how forecasting can potentially harm people, create hazardous environments, or contribute to significant emotional and psychological distress.

4.1.1 Physical injury

- *Inadequate fail-safes* Forecasts of natural disasters can have dire consequences. In the case of hurricane forecasts: "There have been instances in the last few years where they just simply got the number wrong. The hurricane took a turn they weren't projecting" (P2). Similarly, earthquake forecasting has proven challenging: "Earthquakes are almost impossible to forecast, but if a forecast says we're safe and an earthquake occurs, it can cost thousands of lives" (P14). In some cases, the issue is not the failure to forecast the event, but a failure to forecast its impact, and plan accordingly: "You produce a forecast of a potential fire without any plans in place to mitigate the effects, and that can effectively amplify the damage" (P19). Similarly, during the COVID-19 pandemic, poor forecasting led to delayed governmental responses: "If the government made a decision based on a poor forecast, you could measure the extra hospitalizations in hindsight" (P21).
- *Exposure to unhealthy agents* When forecasts fail to forecast public health crises or environmental hazards, people may be left unprepared for the consequences, leading to substantial physical harm. One healthcare expert described the potential harm posed by inaccurate forecasts in family planning: "Women who rely on short-term contraceptive methods face unplanned pregnancies if forecasts fail to deliver their needed protection on time" (P8). Another participant recalled the L'Aquila incident: "In Italy, some forecasters were jailed for failing to forecast an earthquake that led to loss of life" (P6).

4.1.2 Emotional or psychological injury

Over-reliance on automation and ML Automated forecasting tools can foster blind trust in automated systems, leading to errors that are difficult to detect and correct, particularly when uncertainty is ignored or human judgment

is replaced entirely. One major issue is that "people tend to only look at the deterministic forecast⁵ and discard the uncertainty bounds that are around it", (P1) which can result in decision-makers overlooking the potential range of outcomes and the associated risks. Furthermore, automation can foster overconfidence, especially with point forecasts that present a single figure, giving the impression that "there's a lot less uncertainty or risk associated with a forecast than there really is" (P6). Another concern is that full automation driven by machine learning could eliminate the need for human forecasters altogether, which alarms some stakeholders. The idea of "an enterprise that's completely driven by cognitive automation and then we don't need forecasters anymore" (P17) raises fears of losing critical human insight, potentially leading to harmful decisions without proper oversight.

- *Distortion of reality or gaslighting* Forecasts can mislead stakeholders, causing them to act on inaccurate information, leading to mistrust and harmful decisions. One participant noted, "If you are forecasting processes with public effects, like healthcare or migration, the harms could range from panic to damaging public reactions" (P14).
- *Reduced self-esteem/reputation damage* Reputational damage can result from both incorrect and correct forecasts. One participant shared: "If you put a forecast out there and it's wrong, you can suffer a reputational risk" (P5). Even correct forecasts may cause harm if misinterpreted: "You can lose credibility not through poor science, but through an inability to effectively communicate it to decision-makers" (P21). This highlights the importance of both accuracy and communication in maintaining trust in forecasting.
- *Addiction/attention hijacking* This harm may be caused by excessive dependence on frequent short-term forecasts. One expert noted that planners often end up "firefighting", constantly reacting to the latest forecast without stepping back for long-term planning, which leads to stress and reactive decision-making (P11).
- *Anxiety, stress, and emotional distress* Forecasting uncertain or negative outcomes can cause significant emotional distress. A notable example is the COVID-19 pandemic, where inaccurate forecasts had widespread mental health impacts. As one participant explained: "We went through all of the economic harm, mental health harm, and the impact on medical services due to incorrect forecasts about lifting lockdowns too early" (P4). Similarly, healthcare forecasts can have a profound emotional impact: "An accurate forecast of an unavoidable illness can ruin your last few years of life" (P6). Another participant illustrated the potential emotional harm in everyday situations: "When I go shopping in the evening and I can't find strawberries anymore, there is emotional distress" (P2). Thus forecasting, even in less critical domains, can evoke anxiety and frustration when expectations are not met.

4.2 Denial of consequential services

This section discusses how forecasting can limit access to essential resources, services, and opportunities, or result in economic losses.

4.2.1 Opportunity loss

Insurance and benefit discrimination Inaccurate forecasts can lead to unintended consequences in identifying and assisting vulnerable populations: "Mapping poverty or any type of aid allocation can cause harm because imperfect models fail to perfectly identify the most vulnerable people, resulting in inefficient use of aid" (P3). Another participant pointed out that this harm could extend to denying access to life-saving products: "If a forecast shows there isn't sufficient market, it may disallow access to a product that could improve health or save lives" (P9).

⁵A point forecast that is represented as a single value summarizing a distribution. Alternatives are an interval estimate that gives a range of likely values, or a full probability distribution.

- *Digital divide/technological discrimination* Marginalized communities can be further disadvantaged by being excluded from forecasting data. One interviewee stressed, "Marginalized communities might be excluded from the data because they're harder to reach, leading to decisions that overlook these populations" (P21). This can exacerbate existing inequalities, leaving certain groups without access to critical services or benefits.
- *Loss of potential investment* Inaccurate forecasts may lead businesses to overestimate or underestimate market demand. One expert explained: "If a manufacturer overproduces based on inaccurate forecasts, they risk losing confidence in the market and may not invest in promising public health products in the future" (P9). In other cases, overly complex forecasting models that yield little business improvement may waste valuable resources: "The harm lies in the opportunity costs of resources invested in a forecasting method that didn't significantly improve outcomes" (P2).

4.2.2 Economic loss

- *Economic exploitation* Detrimental decisions may be based on flawed forecasts, such as over-committing resources or accepting poor employment conditions: "For long-term investments, inaccuracies in forecasts can hurt the business, especially when big investments are made in infrastructure like data centers" (P18).
- *Misdirection of resources* Inaccurate forecasts also lead to wasted time, money, and effort. This issue was particularly evident in the construction and supply chain industries, where inaccurate forecasts resulted in the misallocation of materials and resources: "The easiest harm to identify is the misdirection of resources due to forecast inaccuracies, especially when cognitive biases like optimism bias affect judgmental forecasting" (P6). This misdirection extends to scenarios where pre-positioned resources for emergency response end up being in the wrong place, causing delays and increased costs (P5).
- *Financial loss* Several experts emphasized the financial damage caused by overproduction or underproduction, leading to excess inventory or lost sales. "If forecasts are too optimistic, companies may overbuy inventory, leading to markdowns or waste" (P17). This financial burden extends across industries, from manufacturing to tech, with one participant describing a situation where billions of dollars in unused servers were wasted due to inaccurate demand forecasting (P18). The economic harm also extended to job losses and reduced competitiveness: "If a company can't sell what it produced, it harms their competitiveness and could lead to layoffs" (P11).

4.3 Infringement on human rights

Flawed forecasting models can lead to breaches of personal freedoms, mismanagement of private data, and environmental degradation.

4.3.1 Privacy loss

Interference with private life As more time series data is generated by vehicles, as well as individual humans equipped with wearable sensors, new opportunities for harm arise. Forecasting models that misuse personal data can infringe upon privacy rights by revealing sensitive information. While these mobility data are usually collected with benevolent intent, they can be repurposed in harmful ways: "The data, especially because it's at the individual level, is arguably being used for other purposes. There are even documented cases of people being persecuted or abducted because of this data" (P3). The ability of forecasting models to misuse personal data underscores the importance of strict data privacy regulations, particularly when individual lives and rights are at stake.

Loss of freedom of movement or assembly Publishing forecasts of migration trends and political protests can cause governments to take preemptive measures to suppress them. In this way, forecasts risk "causing the thing you're predicting to happen" (P5), demonstrating the challenge of balancing the need for forecasting with their potential risks to freedoms.

4.3.2 Environmental impact

- *Exploitation or depletion of resources* Forecasting is frequently employed in the energy sector, where over/underforecasts of energy demand can cause serious, but often, asymmetric harms at the societal level. Energy forecasts can also have indirect impact on the environment by shifting investments in other types of energy such as renewable, nuclear, etc. More directly, forecasting can also lead to significant environmental impact, particularly through the exploitation or depletion of resources. Over-forecasting, for example, can lead to the over-extraction of resources, with significant environmental and economic consequences: "If you can get more accurate forecasts, there will be less waste, less things going to landfill" (P6). Another participant noted that when products are over-forecast and over-procured, "There is then the whole issue of waste disposal. How do you destroy products? Not just the products themselves, but also the packaging and everything that goes along with that" (P9).
- *Waste* Inaccurate forecasts can lead to waste, particularly when excess products are procured that cannot be sold: "When you get more than you sell, you need to go through markdowns, and for some items, they will just become waste because they are perishable" (P10). This problem is widespread, affecting industries ranging from pharmaceuticals to retail: "We've seen national governments over-forecast and over-procure products, which leads to large quantities of expired or unused products needing to be destroyed" (P13).

4.4 Erosion of social and democratic structures

This section examines how inaccurate or biased forecasting can erode social and democratic structures, focusing on two types of harm: manipulation and social detriment. The findings indicate how forecasting can be used to mislead or exploit people, reinforce stereotypes, and potentially marginalize underrepresented communities.

4.4.1 Manipulation

Misinformation Forecasts can spread misinformation by presenting biased or incomplete information, often influencing public perception and decision-making: "forecasts [can be] used for political reasons to sway decisions, sway policy, or sway people's opinions" (P12). This intentional use of misleading forecasts can cause significant harm, if people use these forecasts without understanding the underlying uncertainties or biases. Misinformation can also foster panic or misguided actions: "They said, 'The scientists have told us it's going to be terrible,' with no nuance or layering of that. And it had the risk, I think, in the media of causing some panic" (P21).

Forecasts can also create a self-fulfilling effect, where public belief in a forecast influences outcomes: "I think one potential risk is that people might accuse you of having caused the thing to happen, or that there's this danger of making things a self-fulfilling prophecy" (P5). This highlights how forecasts can shape societal behavior in ways that inadvertently validate or invalidate their forecasts.

Behavioral exploitation Forecasts based on behavioral patterns may exploit personal habits or biases, guiding people to make decisions that align with the forecast rather than their best interests. In some cases, forecasts

are intentionally leveraged to drive particular behaviors. One participant explained, "There are people who use forecasts or media coverage of high-profile incidents to sell the message, such as vaccinations, regardless of how ill-founded or incorrect the forecasts are" (P4).

Furthermore, self-destructive forecasts can also harm democratic processes, such as voting behavior: "A classic example is opinion polls where you forecast that one party is going to win an election, and voters decide not to bother voting... Opinion poll forecasts have been banned in some countries because of their danger of influencing the electorate, and possibly damaging democracy" (P6).

4.4.2 Social detriment

Stereotype reinforcement and loss of representation Forecasts that rely on historical data can perpetuate harmful stereotypes, particularly in fields like employment, education, and criminal justice. Such forecasts may reinforce existing biases and contribute to systemic inequality: "If our data is on only a subset of the population, and then we forecast that ... marginalized communities might be excluded from the data because they're harder to reach" (P21). Similarly, forecasts can lead to the loss of representation for minority or marginalized groups. Forecasting models based on aggregated data may obscure the specific needs of these groups, leading to decisions that fail to account for their unique circumstances: "If our data is only on a subset of the population ... it can set up socioeconomic or marginalized communities to be excluded" (P21). Thus, overly simple forecasting methods can marginalize vulnerable populations, rendering their needs invisible in decision-making processes.

5 Discussion

5.1 Potential harm from forecasting

Our analysis of the interviews suggests four broad types of forecasting harm, depending on the intention of the forecasters and the accuracy of their forecasts, as shown in Figure 3. Each has different ethical implications, highlighting the complex ethical and practical challenges in forecasting. For instance, one conflict is the probabilistic nature of forecasting harms and ethical practices that ascribe moral blame based on an actor's intent to cause harm.

Unintentional harm from inaccurate forecasts Unintentional harm can arise when forecasters produce poor forecasts, whether through a lack of suitable data, inadequate training, the intrinsic noise in the process, or a combination of these factors. For example, a forecaster provides a forecast for a humanitarian crisis, but it does not accurately forecast the hardest-hit areas. As a result, aid is misallocated, and vulnerable populations do not receive the necessary resources. One interviewee explained: "your models are going to be imperfect ... you're creating some indirect harm because you didn't perfectly identify the most vulnerable people."

Further analysis might seek to identify criteria for evaluating the causes of forecast inaccuracy. If the inaccuracy stems from oversight, or negligence in the data collection or model-building process, forecasters or their organizations might be held legally or morally responsible for resulting harms. But if forecasters took all reasonable precautions in developing their forecasts, they might be released from liability for any harms that actually result. This roughly captures what eventually happened to the seismologists in the L'Alquila case, and more generally parallels how determinations of malpractice are made in medical contexts. These considerations illustrate the need for more work aimed at integrating forecasting-specific practices into traditional theories of harm in law and ethics.

Forecast Accuracy

Figure 3: Forecast harm matrix

- *Unintentional harm from accurate forecasts* Accurate forecasts, while informative, can unintentionally inflict harm due to their impact on human behavior and emotional well-being. For instance, a healthcare forecast predicting the progression of an inevitable illness or genetic condition may cause severe psychological distress, creating ethical dilemmas for individuals and their families and often diminishing quality of life. Similarly, an accurate recession forecast can prompt consumers and businesses to cut spending preemptively, inadvertently accelerating the economic downturn it aimed to address. In both cases, the accuracy of these forecasts does not mitigate their potential to cause harm through unintended consequences on behavior, underscoring the complex role of forecasting in high-stakes domains. This scenario suggests that even with good intentions, forecasters in sensitive fields must carefully consider the broader impact of their predictions, particularly in areas where public trust and well-being are at stake.
- *Intended harm from inaccurate forecasts* An actor or organization can knowingly publish an inaccurate forecast, which then indirectly inflicts damage due to its likely effects on human behavior akin to yelling "fire" in a crowded movie theater. For example, a forecaster may knowingly publish a false forecast suggesting that COVID-19 cases are decreasing and that the virus is no longer a threat, despite clear evidence to the contrary. As a result, people stop wearing masks and taking precautions, leading to a new wave of infections and deaths. Alternatively, a stock price forecaster may deliberately forecast a high price in order to inflate the price before selling their stocks. Fortunately, known cases of intentional forecasting harm are rare. Yet one interview participant explained that forecasters can knowingly manipulate the data or the forecast, creating an intentional disconnect between the forecast and the actual expected outcomes, with the conscious goal of inflicting harm.

This scenario could be viewed as motivation for professionalization and licensing of forecasters, at least for those working in high-stakes domains or who occupy institutional roles that rely on public trust and support. Furthermore, the intentional harm scenario suggests drawing on a similar distinction made in law between civil and criminal wrongs. Our study has implicitly assumed most forecasting harms are unintentional. The possibility of bad actors inflicting intentional forecasting harms could motivate the need for criminal sanctions on behalf of the state as a means of protecting society's interests.

Intended harm from accurate forecasts Even accurate forecasts can lead to harm if they are misused by malicious actors. While a forecaster may have good intentions, their forecasts can be exploited by adversaries for harmful purposes. As one interviewee explained, "you could imagine that other war parties... use this in a different way." For example, a forecast population displacement due to conflict is intended to guide humanitarian efforts to provide aid. However, hostile forces use the same forecast to target vulnerable populations, attacking areas where displaced families are expected to gather. Another example could occur in military scenarios, when accurate forecasting models are used to plan and time strategic disruptions to an enemy's supply chain (Layton 2021).

However, the majority of risks arise from the complexities of forecasting, rather than deliberate malice. Interviewees emphasized that forecasters generally aim to produce the most accurate forecast possible. Yet inherent limitations of the forecasting process, imperfect data, or unforeseen events, can still lead to unintended negative consequences.

5.2 Domains prone to harm

AI researchers and legal scholars find it useful to designate applications of AI as falling into discrete risk tiers. More generally, the legal concept of *proportionality* relates a risk tier to a standard of safety or scrutiny (Karliuk 2023). Higher risk applications require proportionally higher levels of scrutiny. We see a similar need to determine risk-tiers for domains where forecasting is commonly applied. Forecasts may cause harm in sensitive domains where human lives, financial stability, and societal well-being are at risk. Healthcare, humanitarian and environmental crises, economics, politics, and other domains where vulnerable populations reside are especially prone to harm, as forecasts can influence critical decisions that have lasting effects on many people's lives.

One interviewee pointed out how politics and healthcare came immediately to mind as domains where incorrect forecasts can cause substantial harm, because these areas often affect large populations and drive policy decisions. Politics directly shapes societal responses, influencing everything from public confidence to policy interventions. So election forecasts, or forecasts about policy decisions, have high harm potential. In healthcare, forecasting errors can have life-and-death consequences. For example, if a pandemic forecast underestimates the spread of disease, healthcare systems may be unprepared, leading to preventable deaths and long-term public health crises. Misleading or overly optimistic forecasts in these sectors can lead to inadequate preparation and insufficient responses, which can ripple through societies.

Humanitarian work is also a domain where the stakes are exceptionally high. Forecasts in humanitarian contexts, whether they involve natural disasters, migration flows, wars, or droughts, are critical for organizing relief efforts and protecting vulnerable populations. As one interviewee noted, in humanitarian contexts, "the stakes are just higher" because the margin for error is slim. A flawed forecast can result in misallocated resources, delayed interventions, or missed opportunities to provide life-saving assistance, potentially with devastating consequences for those in need.

Forecasts that involve vulnerable populations—whether in humanitarian crises, economic downturns, or migration flows—are fraught with risk. Vulnerable populations often rely on external support, and inaccurate forecasts can exacerbate an already precarious situation. If a forecast underestimates the needs of a vulnerable population, the resulting lack of support can deepen the crisis. One interviewee remarked that when dealing with vulnerable populations, the opportunity for harm is even greater, as they have fewer resources to adapt or recover from forecastrelated decisions. This is especially true in contexts where the forecast shapes policy or public intervention, such as migration or healthcare. The discussion of vulnerable populations highlights the need for greater clarity around the social role and responsibilities of forecasters. In biomedical ethics (Beauchamp & Childress 2001), special considerations apply when experimental participants belong to vulnerable populations, such as the homeless, political refugees, or those suffering from mental illness. And in law and medicine, exploitation of the vulnerable is to some extent mitigated by professionalization, codes of ethics, and community and evidence-based quality of care standards.

The potential for harm also extends to economic and financial forecasts, which can cause widespread disruption and loss. Financial forecasts shape decisions in markets and firms, influencing everything from inventory orders to asset pricing. As one participant pointed out, an incorrect financial forecast can lead to significant economic loss, whether through overpricing or underpricing assets, or causing market disruptions that impact the broader economy. Additionally, economic forecasts that shape public policy, such as those predicting inflation or employment trends, carry risks for the entire population, particularly if they inform policy decisions that fail to address underlying economic vulnerabilities.

An important thread running through these domains is that harm from forecasting is not only linked to the forecast itself, but also to its public perception and the societal response. In areas like healthcare, migration, and even economic forecasting, the way people react to forecasts can amplify or mitigate the harms. As one interviewee explained, "harms are associated with the sort of response that the public tends to have to such forecasts." This underscores the behavioral and psychological consequences of a forecast that go beyond its predictive accuracy. For example, a public panic in response to a pessimistic migration forecast can lead to hasty political decisions, potentially exacerbating the situation. Currently, forecasters receive little to no formal training or education about how forecasts may be psychologically perceived by an audience.

Ultimately, the societal impact of a forecast is closely tied to the domain it addresses. Forecasts related to elections, inflation, pandemics, or migration have far-reaching effects on policy-making and public sentiment. As one interviewee summarized, "the potential harm of a forecast is directly related to the impact that forecast will have on human life." In these cases, even a small forecasting error can have serious consequences, from undermining public health efforts to causing financial instability or social unrest.

5.3 Possible mitigation strategies to minimize harm in forecasting

Our interviewees emphasized that minimizing harm in forecasting is a shared responsibility between forecasters and decision-makers. Furthermore, respondents suggested that to improve forecasting transparency and accountability, forecasters should clearly communicate model assumptions, uncertainties, and potential impacts, while taking ownership of their forecasts, particularly in high-risk domains. Moreover, several interviewees stressed the importance of understanding the audience and purpose of forecasts, raising concerns about misuse, and the value of using simulation-based approaches to illustrate potential outcomes.

Conversely, the interviewees largely agreed that decision-makers should critically engage with forecasts, assess their limitations, and ensure they are fit for purpose. Both parties should collaborate to establish feedback loops, refine forecasts, and promote non-harmful use, while recognizing that forecasts are not absolute truths but epistemic tools that guide decisions within a broader context of uncertainty.

Drawing on these and other points, we have identified ten approaches to mitigate the harm that can arise from forecasting, which are illustrated in Figure 4. These can help forecasters reduce the likelihood of harm while ensuring forecasts are used appropriately by decision-makers.

Figure 4: Mitigation strategies extracted from interview analysis

- 1. Tailor forecasts to the decision context Interviewees emphasized the importance of tailoring forecasts to the specific needs and contexts of decision-makers. Forecasts that are not aligned with decision-making processes can cause harm, as stakeholders may misunderstand their intent or limitations. One participant explained, "we should communicate that these forecasts are made under certain assumptions, and the assumptions may be, for instance, that things will continue as they are now." Another example highlighted the need for qualitative information alongside the quantitative, explaining the use case and time horizon so that decision-makers can properly apply the forecast. Close collaboration with decision-makers is essential to ensure that forecasts are tailored appropriately and that the assumptions and limitations are fully understood.
- 2. Produce forecasting model cards Forecasters should ensure that forecast consumers—the stakeholders— know what the forecast represents to prevent potential manipulation or misinterpretation. Forecast stakeholders should have access to information about the data, models, assumptions, the conditions under which the forecast applies, and forecast variability. Such transparency enables stakeholders to properly interpret and trust the forecasts. *Model cards* (Mitchell et al. 2019) could a viable solution to promote more standardized forecast reporting. Standardized reporting is used in clinical trials to summarize drug efficacy data and convey the uncertainty attached to regulatory decisions (Fischhoff & Davis 2014). Forecast model cards could provide a standardized disclosure mechanism, not unlike food nutrition labels or publicly available financial reports for firm investors, that help forecast stakeholders

grasp the limitations and potential biases of the forecasts produced by a forecasting model. For instance, model cards could help guard against the file-drawer problem in forecasting, and mitigate the "problem of many hands" by encouraging accountability for forecasts by giving the name of an accountable individual or organization to be contacted in case of concern. Further, publicly available forecasting model information would allow stakeholders to engage in more informed decisions about where forecasting should and should not be applied, given the level of forecasting uncertainty and the costs of error.

- **3.** *Communicate uncertainty* A consistent theme in the interviews is the need to communicate uncertainty clearly. One participant highlighted that "providing just one number is never good enough in decision-making systems." Forecasters must express the uncertainty inherent in their models and provide a range of potential outcomes rather than a single point forecast. Without this, decision-makers may make incorrect assumptions about the certainty of the forecast, leading to misinformed decisions. Another interviewee emphasized, "Always speak to the assumptions you are making when you are doing the forecast and always talk about the uncertainty you have on your results," noting that if uncertainty isn't communicated, stakeholders often make their own, sometimes harmful, assumptions. Communicating uncertainty is critical to minimizing harm, particularly in fields where decision-making is sensitive to small changes in the forecast.
- **4.** *Obtain feedback from actors* Several interviewees mentioned the need for feedback from decision makers. As one participant explained, "If you simply send your forecast off to somebody and never hear anything else from them, then you don't know whether it's caused harm or not." Regular communication and feedback loops between forecasters and stakeholders are critical to ensuring that forecasts are used correctly and understood within the broader decision-making context. Consulting with a wide range of stakeholders, including those directly impacted by the forecast, helps forecasters identify potential issues early and adjust forecasts to meet user needs more effectively.
- **5.** Use simple and interpretable models where possible Overly complex models can pose a risk if they are difficult for decision-makers to understand and apply. As one interviewee noted, "If the model is too complex and people are not using it, you're also somehow doing harm." Simpler models that are easier to understand are sometimes more effective than sophisticated ones, particularly when decision-makers are unfamiliar with complex statistical techniques. Ensuring that models are interpretable and accessible increases the likelihood of adoption and appropriate use, avoiding harms that arise through lack of trust in the forecasts.
- 6. Adhere to best practices for model training and evaluation Adhering to best practices in model training and evaluation is critical to ensuring forecast accuracy and minimizing harm. One interviewee highlighted that accuracy is closely tied to reducing harm: "If accuracy is related to reduction of harm, then a recommendation would be to follow best practices in both the training of the models and the evaluation of the models." Additionally, forecasts should be benchmarked against simpler approaches to ensure they provide meaningful improvements. Proper evaluation helps to avoid reliance on overly complex models that may not offer substantial benefits over simpler alternatives.
- 7. Create bias audits Bias in forecasts can lead to harm, particularly when certain populations or perspectives are neglected. Interviewees noted the importance of auditing models for biases at each stage of the forecasting process. Furthermore, diverse teams can help mitigate blind spots and identify potential harms that a homogeneous team might overlook. One interviewee emphasized that "having a diversity of perspectives" on the forecasting team is crucial to detecting problems early and ensuring that forecasts serve all affected groups fairly.

- 8. Engage in scenario planning and risk auditing Engaging in scenario planning and risk audits can help forecasters anticipate potential harms. One interviewee suggested that, especially in conflict-affected areas, forecasters should "think really out of the box" and engage in exercises to assess what wrong could happen if a forecast is published. By proactively identifying risks, forecasters can implement safeguards to reduce the likelihood of harmful outcomes.
- **9.** Control who can access forecasts and provide usage guidelines Controlling who has access to forecasts and how they are used is another potential mitigation strategy. One interviewee suggested that published forecasts "shouldn't just be consumed by anyone for any reason," arguing that access control mechanisms can help ensure that forecasts are used appropriately. Proper onboarding processes and close monitoring of how forecasts are applied can help prevent harmful misuse. Granularity is also important—forecasters should provide clear guidelines on how to use forecasts at different levels of aggregation (e.g., weekly versus monthly) to ensure that users apply them correctly.
- 10. Focus on high-risk areas Another strategy emphasized was the need to prioritize areas where forecasting could cause the most harm. One interviewee used the analogy of "focusing on the tigers and not the mice," meaning that forecasters should concentrate on areas where errors would have significant consequences, such as high-stakes sectors like healthcare, supply chains, and humanitarian responses. Not all forecasts carry the same level of risk, and focusing on areas with the greatest potential for harm allows forecasters to minimize the likelihood of serious negative outcomes. By identifying the most critical areas, forecasters can work to improve accuracy and relevance where it matters most.

6 A Research agenda

Based on our preliminary study and interviews with forecasters, we describe some promising areas of future research.

Compensation for forecasting harms Context matters in determining what constitutes a harm. Just as in clinical experiments, consent to the risks of harm could in principle morally legitimize harms stemming from forecasting. To date, however, the lack of research attention paid to forecasting harms suggests this consent has been largely tacit and presumed. Consent is especially relevant for vulnerable populations which often must make important decisions under duress. We hope our research can stimulate more transparent discussion among forecast stakeholders about which risks related to forecasting ought to be explicitly consented to, and which not.

Drawing on an example taken from climate change and the ethics of corrective justice, we offer one suggestion for navigating the complex tradeoffs between the benefits and risks of forecasting. Just as some corporations voluntarily pledge to offset their greenhouse gas emissions (Hyams & Fawcett 2013) (e.g., by planting new trees), organizations doing large-scale forecasting that creates relatively trivial harms, such as representational harms (Suresh & Guttag 2021), or minor allocative harms related to mis-forecasting the supply/demand of certain non-essential items, can donate or contribute to society in other ways. The idea here is that if it is practically impossible to separate out the good from the bad effects of forecasting in society, then as an alternative, those bad effects might be morally mitigated by compensatory actions.

Developing "fair" forecasting metrics A major area of forecasting research concerns the development and analysis of accuracy metrics (Hyndman & Koehler 2006, Davydenko & Fildes 2016). Yet most work in fair machine learning focuses on binary classification contexts. For instance, one measure of discrimination compares true positive rates across groups, a fairness metric known as *equal opportunity* (Hardt et al. 2016). This leaves

practitioners working on numerical prediction problems with little guidance on what constitutes "fair performance" of a forecasting model. We encourage researchers interested in the ethics of forecasting and questions of distributive justice to develop "fairness" metrics suitable for forecasting contexts. For example, mean error can indicate systematically over- or under-forecasted values, but one may wish to evaluate how such biases are distributed across society. There may be valid ethical justifications for distributing the harms associated with these errors across society (and their associated social and business burdens) to address historical inequities. At the same time, we should caution against narrowly treating fairness as a property of forecasting algorithms, independent of larger social contexts in which forecasting models are deployed.

Explainability, transparency, and contestability of forecasts Potential harm is reduced if decision-makers are provided with understandable explanations for highly sophisticated forecasts. AI researchers are increasingly focused on explaining the output of predictive models to non-experts using a variety of explainable AI techniques (Arrieta et al. 2020). Advances in this area have come partly in response to new legislation and growing consumer demand for explainable predictions, especially in high-stakes contexts related to finance, medicine, and education. A key question is whether more inherently interpretable but potentially less accurate methods be used, rather than more data-driven blackbox models (Rudin 2019). To date, most of the research and public discussion around transparency has centered on applications of supervised machine learning, but has not addressed the area of time series forecasting methods.

Political and legal researchers have focused on the importance of being able to contest automated decisions, and for holding people and organizations accountable, both legally and ethically, for when predictions go wrong. We believe that similar lines of research will be important in the ethics of forecasting, thus motivating our proposal for developing "forecasting model cards" which list accountable persons and organizations.

- *Addressing forecasting inconsistency* Forecasting models trained on the same data can lead to different forecasts because the optimization methods often rely on random number generation and, by chance, randomly selected initial parameter values can converge to one of many possible local optima in a complex loss landscape. Other sources of inconsistency are the of choice of series length, training/holdout partitioning, performance measures, and even the software used. The resulting inconsistency in forecasted values can reduce end-user trust in forecasts as they may view the forecasted model as unreliable.
- *Managerial override of forecasts* Many interviewers noted that attempts to adjust a forecast away from its initial value usually leads to more harm than benefit. One reason is managers not understanding the inherent noise in the process, and reacting to random variation rather than signal. Another reason is that there is often a lag between a corrective action and the observable consequences of that action. If, for example, a product is forecasted as having low demand, a marketing team may spend months developing an appropriate strategy to counter-act this forecast. But the marketing intervention will take time before its effects on demand are noticed. In other words, there is a temporal miscalibration between corrective action and outcomes that can lead to exacerbation of harms in certain cases. As suggested in Shmueli & Lichtendahl Jr (2016), to address this issue, organizations can collect data on when such corrections occur and later compare these corrected versions against the original version when the actual data arrive. A similar proposal has been made in criminal justice risk assessments when judges override algorithmic recommendations (Koepke & Robinson 2018). To date, little research has tried to explore the conditions under which managerial corrections ultimately help or hurt forecasting process.

Statistical education and training for managers Lastly, many interviewers noted that managers—a major audience for forecasts—often do not grasp the differences between point estimates and distributions, leaving them confused or angry when forecasts "turn out wrong". This reaction demonstrates a need for greater education in probability and statistics for business students and managers.

7 Conclusions

Considerable research attention has focused on the harms of AI/ML, yet our understanding of forecasting harms remains underdeveloped. The special nature of forecasting pipelines, data, and applications makes it difficult to apply existing theories of harm and AI/ML harm frameworks to the forecasting context. To remedy this gap, we combined an AI-driven analysis with an inductive, human-led thematic analysis to identify four emergent themes of harm related to forecasting. These themes were synthesized with philosophical and legal insights about the concept of harm, as well as specific findings from research on the harms of AI/ML, to identify and taxonomize the harms of forecasting. We defined harm as the unjust defeating of the interests of an individual or collective such as a society, organization, or ecological system, during the practice of forecasting. This definition helped us develop a taxonomy of harm focused on the intent and accuracy of a forecasting model. Besides contributing a novel organizational framework for understanding harms relevant to forecasting, we also outlined several harm mitigation strategies.

Our study revealed that many of the potential harms of forecasting lie not just in the act of forecasting itself, but in the publication of the forecasts, and in how forecasts are used to inform behaviors and decisions that impact broader social and ecological systems. Whether in inventory management, financial markets, or public policy, the risks are directly tied to the actions taken based on those forecasts. The question is not whether a forecast is always right, but whether the net benefits of forecasting outweigh the risks. This is arguably a policy or value question that must be decided by particular political communities. Our harm taxonomy can promote a more comprehensive public deliberation regarding the nature of the trade-offs involved.

One related question concerns responsibility for the harms caused by forecasting. Whether a poorly produced forecast actually results in harm can depend on luck. This complexity may spur discussion within the forecasting community around the adequacy of existing ethical guidelines or help inspire new "standards of care" uniquely adapted to forecasting. A greater appreciation and recognition of the harms of forecasting may even motivate steps towards the professional licensing of forecasters, particularly those working in high-risk domains or during emergency periods such as a global pandemic. Indeed, professionalization could represent a broader, systemic approach to harm reduction that, for instance, involves institutionalizing some of the harm mitigation strategies discussed in Section 5.3.

Our focus on forecasting harms may tempt one to conclude that forecasting is inherently dangerous. This conclusion should be avoided. We believe that while forecasting can lead to harm, abandoning it completely would not eliminate risk—it would only make us blind to it. If organizations were to completely abandon forecasting, this would likely lead to greater uncertainty and inefficiency in many important processes throughout society. Forecasting, even when imperfect, offers a mathematically sound basis for decision-making that is often superior to human intuition. For example, without forecasts, supermarkets might overstock products, leading to waste and inefficiency, as one interviewee explained. The key is not to stop forecasting altogether, but to focus on identifying and mitigating potential harms, with the goal of gradually moving towards more responsible forecasting practices.

This work therefore aims to provide an empirical grounding for the development of more reflexive and responsible forms of forecasting in society. Reflexivity is an important aspect of science and responsible innovation (Stilgoe et al. 2013). Responsible forecasting requires critically self-examining the activities, commitments and assumptions on the part of actors and institutions who use forecasting. Having a nuanced and open discussion of forecasting harms may be uncomfortable, especially when practical questions of legal liability arise. Still, the alternative of moral disengagement appears to us an even less attractive option. As one interviewee stated, "forecasting is not just an [abstract] exercise... there are [concrete] implications." Taxonomizing and recognizing the specific harms stemming from forecasting can help organizations take initial steps towards becoming more responsible, transparent, and effective in minimizing and preventing the inherent risks of forecasting.

Declaration of Conflicting Interests

The author(s) declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.

A Interview protocol

General questions:

- 1. Can you describe your role concerning forecasting systems?
- 2. How long have you worked in this role?
- 3. Are you an academic or professional?
- 4. What is your role within the organisation if you are a professional (decision-maker or forecaster)?

Forecasting workflow:

Figure 1 highlights the main steps in a forecasting workflow.

Questions about harm in forecasting:

- 1. Based on your experience, do you believe that forecasting can potentially cause harm?
- 2. What types of harms do you think are associated with publishing a forecast?
- 3. Can you share with us some examples of how published forecasts have caused harm in the past?
- 4. Are there certain domains (e.g. healthcare, climate change) where publishing a forecast is particularly prone to generate harm?
- 5. What role do forecasters play in identifying potential harms associated with publishing forecasts?
- 6. What role do forecasters play in mitigating those potential harms?
- 7. How can forecasting systems be improved to minimize harm resulting from published forecasts?
- 8. Based on your experience, what are some common types of harm that can occur in the forecasting workflow prior to publishing, including stages like data collection, model selection, and accuracy evaluation?

B Summary of participants

| Code | Perspective | Role | Sector | Interview length (minutes) |
|------|--------------|--|------------------------------|-------------------------------|
| P1 | Practitioner | Customer manager | Software vendor | 61 |
| P2 | Practitioner | Data Scientist | Retail | 55 |
| P3 | Academic | Professor | Computer Science | 55 |
| P4 | Academic | Research Fellow | Population and Public health | 53 |
| P5 | Practitioner | Emerging Technologies lead | Goverment | 60 |
| P6 | Academic | Professor | Business | 54 |
| P7 | Practitioner | Marketing manager | Software vendor | 64 |
| P8 | Practitioner | Project Manager | Public health | 62 |
| P9 | Practitioner | Senior analyst | public health supply chain | 47 |
| P10 | Practitioner | Data Scientist | Retail | 57 |
| P11 | Practitioner | CEO | Supply chain software | 57 |
| P12 | Practitioner | Director | Business | 44 |
| P13 | Practitioner | Analyst | Global public health | 58 |
| P14 | Practitioner | CEO | Software company | 40 |
| P15 | Practitioner | Demand planner | Pharmaceutical | 65 |
| P16 | Practitioner | Scientific lead | Humanitarian | 54 |
| P17 | Practitioner | Director for data science and service innovation | Software | 57 |
| P18 | Practitioner | Product manager | Technology | 56 |
| P19 | Academic | Professor | Business | 50 |
| P20 | Practitioner | Data Scientist | Retail | 55 |
| P21 | Academic | Professor | Infectious disease | 43 |

 Table 3: Summary of participants' domain, expertise and interview length

C Sample evidence from the interview quotes

| Description in Miscrosoft | Description adapted to forecasting | Quotes from interviews |
|---|--|--|
| Real-world testing may insufficiently consider a diverse set of users and scenarios. | Forecasting models may lack mechanisms to account for unexpected conditions, leading to inaccurate predictions in diverse, real-world scenarios. | (P2) "Hurricanes are a big causer of damage, and it's mostly in the Southeast of the United States, and the representation of the hurricane forecasts they wisely show it as a conic – the path with – and certainly a range around it and so on. But even with that, it's still imperfect and there have been instances in the last few years where they just simply got the number wrong. The hurricane took a turn they weren't projecting." (P14) "Earthquakes in particular I think are almost impossible to forecast, but if a forecast is produced saying, 'No, we're reasonably safe for the next few years,' and an earthquake occurs, it can cost thousands of human lives." (P16) "So the actions that were taken were not strong enough, were not adequate." (P19) "So you produce a forecast of potential fire without any plans in place to mitigate the effects and that can just effectively amplify that." (P21) "if a government, say in COVID made a decision to respond or not respond based on a forecast. And if you could establish that that objectively was a poor decision in hindsight, say, and measure the extra number of hospitalisations, yes, it could still happen." |

Risk of Injury / Physical injury / Inadequate fail-safes

Risk of Injury / Physical injury / Exposure to unhealthy agents

| Description in Miscrosoft | Description adapted to forecasting | Quotes from interviews |
|---|--|---|
| Manufacturing, as well as disposal of technology, can jeopardize the health and well-being of workers and nearby inhabitants. | Poor forecasting, especially in health or environmental sectors, could expose stakeholders to unforeseen risks, such as public health hazards or environmental crises. | (P7) "Earthquakes in particular I think are almost impossible to forecast, but if a forecast is produced there saying, 'No, we're reasonably safe for the next few years,' and an earthquake occurs, it can cost thousands of human lives. In fact, some Italian – I wrote this in a book, but it's a few years ago. I've forgotten the details. Some Italian forecasters actually went to jail because they failed to forecast an earthquake." (P6) "I guess my context and experience is only in healthcare, and it's probably a good domain where the harm affects lives. And so it's not just about, 'Well, I won't have my laptop on time or my phone on time.' It's about women who rely on a short-term contraceptives where it is needed tomorrow, and that can affect unplanned pregnancies should women not have that protection" (P8) "I think there was that case in Italy, the legal case of, was it earthquake or volcano issue where some scientists got in trouble for not effectively communicating the risk of that natural disaster happening. And perhaps there was a lo- – there may have been loss of life, loss of property because of that. So there are potential physical, environmental types of dangers from forecasting, from inadequately communicated or just poorly inadequately created forecasts. |

| Description in Miscrosoft | Description adapted to forecasting | Quotes from interviews |
|---|---|--|
| Misguided beliefs can lead users to trust the reliability of a digital agent over that of a human. | Blind faith in automated forecasting tools without proper validation may lead to significant errors, causing stakeholders to trust flawed predictions over expert judgment. | (P1) "People tend to only look at the deterministic forecast and discard the uncertainty bounds that are around it which could be quite large." (P6) "I think the first is over-confidence. I think particularly with things like point forecasts where you present a single figure, it can create the impression that there's a lot less uncertainty or risk associated with a forecast than there really is." (P17) "So one thing that really scares some of our clients or some people that we work with is the full automation that machine learning can cause. Like the idea that an enterprise that's completely driven by cognitive automation and then we don't need forecasters anymore." |

Risk of Injury / Emotional or psychological injury / Overreliance on automation

Risk of Injury / Emotional or psychological injury / Distortion of reality or gaslighting

| Description in Miscrosoft | Description adapted to forecasting | Quotes from interviews |
|---|---|--|
| When intentionally misused, technology can undermine trust and distort someone's sense of reality. | When misused or manipulated, forecasts can distort stakeholders' perception of future events, leading to mistrust or harmful decisions based on inaccurate predictions. | (P1) "We have a lot of not firefighting, but pre-firefighting [laughs] people who are – who tend to overreact to a time change in the forecast." (P3) "So for example do people then send more law enforcement or more – you know, somehow try to curb undocumented migration into certain parts of the US more. So it's maybe slightly less direct physical harm but it still has an element of physical harm just showing presence of people in areas where they're not supposed to be, or maybe they're not known to be also." (P4) "Right. And so the first one, working with public health, and especially public health in near real-time, they're very risk averse. It's a cultural thing, and obviously given some of the data they work with it's entirely understandable. But from their perception, so I haven't been allowed to publish my near real-time flu forecasts in real-time. We've been able to publish them in academic papers after a flu season, and retrospective analysis then showed and talked about where the forecasts did and didn't perform well. But the public health staff, for better or worse, have a default mindset that making anything available publicly is opening themselves up to criticism and just negative impacts." (P8) "But if the purpose of the forecast is not understood, so for example like a short-term forecast because of the data that was used. So let's say three to five years, but they take it and then go off with a business plan that could be like five to ten years in the making to see that demand be generalised into actual sales. And so there's just, I guess, general frustration in that aspect." (P9) "They then really felt somewhat betrayed by the donor community and by feeling like they'd done their part. So that's more of the like trust, and then wanting to engage with this public health community moving forward and then feeling – I assume it had detrimental affects to their business as well." (P10) "Th's really hard to justify why you have larger or small numbe |

(P3) "now are there areas we are being wrong is more or less harmful, I think maybe based on the horizon on which we're forecasting, for example for macroeconomic, all these kind of things, 10 years, 20 years ahead, does that really change that much things. There will be so much things that's going to change anyway in between that the assumptions will be totally different, and it will appear to be wrong. And there are so many reasons why it's going to be wrong, but I think it's not going to be that much harmful because it's the ... Maybe based on the horizon of the forecast it changed the - or maybe not the horizon, but the horizon of the decisions, there are some ways to - some alternatives or ways to change or re-impact the decisions if we were wrong. It's the ability to - you know, the agility, to say, 'OK, we were wrong, but we could soften the impact.' We still have time to soften the impact." (P1) "So how close is the wall? You know, you are running just - and you're going to hit the wall, how close is the wall, and do you have time to react and to turn left or right to avoid it or not? That could be a way to say OK, this domain is more likely to be harmful because if I'm wrong I have no Plan B. Whereas in other domains there might be some Plan B. For example, climate change, maybe 20 years or 30 years ago there were some - a lot of Plan B, and people tend to say, 'OK, we're not going to make any decisions anyway,' so ... And right now it seems like there's no - not that much Plan B, [laughs] and we are already close to the wall. And it's not a question of forecast anymore, by the way, it's a question of a decision, and it could harm. [Laughs]. (P6) "the harm was to the operations department who couldn't cope. They were believing the forecasts, at least for a few weeks, and they were unable to cope with getting out the welcome packs to customers and connecting customers and

so on. So the customers were suffering through delays because the forecasts were

| Description in Miscrosoft | Description adapted to forecasting | Quotes from interviews |
|--|--|---|
| Some shared content can be harmful, false, misleading, or denigrating. | Inaccurate forecasts could harm the reputation of individuals, businesses, or institutions that depend on them, potentially leading to diminished trust and credibility. | (P2) "And if of course you are in the business of alarmism, and your livelihoods depends on getting donations from people who think like you are, then if these people donate less because they're less alarmed nowadays now that they economists have published their forecasts, then this may also hurt you financially and of course in terms of status and all kinds of other things that people rely on." (P5) "There can be a reputational risk to being wrong if you put a forecast out there and say this is what we think is going to happen. I mean I still remember when in 2008 we had the global financial crisis. The former Fed Chairman, Alan Greenspan had a book that was still on bookstore shelves at the time that this happened, saying that he didn't think there'd be another recession in 50 years. So there's a reputational cost of being wrong." (P10) "Whenever your forecast is low and you're losing some demand, yes people tend to criticise that this is due to the forecast and ignoring the fact that this is supposed to be a stochastic type of signal and there's supposed to be error there." (P11) "So I think the unspoken harm outside of the forecasting or demand planning departments is the fact that it's the most thankless job around if you're the one in charge of that forecast." (P13) "I think another example is what I alluded to previously of forecasts that have come out under one set of conditionsThen they made decisions around setting up their production in line with those forecasts and then the circumstances changes and those volumes didn't materialise, and they then really felt somewhat betrayed by the donor community and by feeling like they'd done their part." (P18) "But because of that 100% accountability that can be created on forecasting, generally forecasting becomes like a Cinderella, right. So, we love Cinderella but at the end of the day, unfortunately, all the blame accumulates on forecasting. I think, mostly it leads to hurting trust in organisations within a big corpor |

deliberately being kept too low."

Risk of Injury / Emotional or psychological injury / Reduced self-esteem/reputation damage

(P17) "It can make you look incompetent in the sense that they say to you, "We're paying you all this money. Why can't you give us a good forecast?" The answer, the scientific answer is, "Well, there's this much level of uncertainty in what you're asking me to forecast." But if your boss is not happy with that you risk damage to your reputation, your career and getting fired for trying to give an honest answer to the organisation."

(P4) "also on the public health staff side, their perception, their reservations are predominantly based around, I guess, loss of trust – loss of public trust in that if they're making poor decisions or they have a lack of knowledge or so on. So for them it's more of a long term. They don't have any immediate concern about a specific forecast, but yes, their concern I think is primarily a loss of trust with loss of public trust. If the forecasts are wrong or lead to poor decisions, for COVID-19 yes absolutely, we were involved in work and saying what do we think, when should we lift different restrictions during the extended lockdowns in Melbourne.

(P16) "But if you start to disseminate impact-based forecasts and they are not right, it can have a large impact on, yes, your trustworthiness. That's a harm, not on the people that use it, but on yourself as an organisation, I guess. (P6) "Damage to the forecasting industry as a result of these things? Well, there's lots of disparaging jokes about forecasters. I'm sure you've heard a few of them. Taleb has said some forecasters cause more damage to society than criminals. He said that in the *Black Swan*. And in 2014 when oil price forecasting as an industry and he said, 'My yearend forecast, there's no future for prediction.'" (P21) "I definitely think that happened in COVID that collectively, as you accumulate more and more forecasts which are wrong because of course, they can't always be right because there's uncertainty. It's very easy to paint a picture of forecasts are useless, even though that's not a rational thing to conclude but it's a very easy story to tell."

(P11) "I've related to the fact that there's no degree of uncertainty inherent in the forecast is that the consumers don't realise or recognise that that number is uncertain and to what degree. And so if things go wrong, the forecaster or demand planner is always blamed"

(P4) "the public health staff, for better or worse, have a default mindset that making anything available publicly is opening themselves up to criticism and just negative impacts."

(P6) "The third thing is that I think the first two things can lead to damage to the forecasting profession. People say, 'Oh, these forecasts are always wrong. These forecasts are inaccurate,' and this can lead people to dismiss forecasts when they're reliable. All forecasts get tarred with the same brush. So there can be damage, I think, to forecasting in general when forecasting can be useful." (P5) "There can be a reputational risk to being wrong if you put a forecast out there and say this is what we think is going to happen. I mean I still remember when in 2008 we had the global financial crisis. The former Fed Chairman, Alan Greenspan had a book that was still on bookstore shelves at the time that this happened, saying that he didn't think there'd be another recession in 50 years. So there's a reputational cost of being wrong. And then I think on the being right side of the ledger, I think one potential risk that can come up if you're right, is that people might accuse you of having caused the thing to happen, or that there's this danger of making things a self-fulfilling prophecy."

(P18) "we basically plan for lots of inventory needs but then we don't necessarily see a demand and then that additional inventory, first it is a financial burden to the organisation. So much money is left. The trust forecasters have within the organisations get a hit as well. And this can happen in the other way as well." (P19) "with the flu forecast in particular, especially early on in a season where there's not much of a signal, there's this quite a wide spread of uncertainty in the forecast predictions. And they – well, some people on the public health side would perceive making that available to the general public as an admission that they don't know what's going on. Even though the uncertainty is appropriate given the available data about how that might play out they see it as being something that a person could easily point at and say it's so uncertain to have – you know, our public health people don't know what's going on."

(P20) "yes, trust is possible. That's certainly one part of it. But, yes and losing trust is a long term negative consequence. And we've seen that and epidemiology in the US and they vaccinate very large under George W. Bush, vaccinate a large proportion of the population and the epidemic didn't develop at all." (P21) "you can lose credibility but not through poor science but through poor inability, say to have effectively communicated it to the decision makers"

Risk of Injury / Emotional or psychological injury / Addiction/attention hijacking

| Description in Miscrosoft | Description adapted to forecasting | Quotes from interviews |
|--|---|--|
| Technology could be designed for prolonged interaction, without regard for well-being." | Excessive dependence on short-term, frequent forecasts could lead to attention being drawn away from long-term strategic planning, causing reactive rather than proactive decision-making. | (P4) "But yes, I guess any forecasts where your population's perception of risk or harm to their self – to themselves and, say, their friends and family, their immediate social networks, I guess I can just see it as a real potential for societal damage. [Laughs]." (P11) "You ask any planner, they're always firefighting. They're going from crisis to crisis. That's not a happy place to be." |

Risk of Injury / Emotional or psychological injury / Anxiety, stress, and emotional distress

| Description in Miscrosoft | Description adapted to forecasting | Quotes from interviews |
|---------------------------|--|--|
| | Psychological and emotional strain experienced by individuals or groups when facing uncertain or potentially adverse future outcomes predicted by forecasts. | (P4) "And if you do it too early you've gone through all of the economic harm, the mental health and wellbeing harm, the impact on medical services beyond COVID-19 such as surgeries and so on, all of these wide-ranging societal impacts. And if you lift the lockdowns too early you then see the disease activity you were trying to prevent. So you've had all of the incidental harm of your intervention and you've lost any potential gain. So that was absolutely the most acute period where a real mistake in the forecast that said, yes, we should open, or yes we should relax some of the restrictions too early, but, yes, we would have gone through a very long, difficult time with very broad societal impact and then thrown away most if or if not all of what we would've hoped to achieved with that" (P8) "for family planning I think the specific harm would be unplanned pregnancy because they don't have their contraceptive methods in time" (P6) "in terms of it's best not to know, there's a terrible disease you may know of called Huntington's chorea. And it's a terrible disease because if your parents had it, you've got a 50% chance of getting it yourself and a 50% chance of passing it onto your children. It's a very life-limiting, terrible illness, but there is a test which will tell you for certain whether you're going to have Huntington's chorea, and it's debatable whether people would want to know that. They might want to know it. And only 5-10% in the USA decide – who may be in danger because their parents have the disease, only 5-10% decide to take the test despite it being perfectly accurate giving them a perfectly accurate indication of whether they'll develop it in the future. So those are some examples I think of potential harm. I'm sure we can go on with many more." (P6) "Another damage, I think, is what I call it's best not to know, and this can apply in healthcare situations where an inaccurate forecast, or even an accurate one, can cause a lot of anxiety and distress which ma |

| Description in Miscrosoft | Description adapted to forecasting | Quotes from interviews |
|---|---|--|
| This includes denying people insurance, social assistance, or access to a clinical trial due to biased standards. | Forecasts used could unfairly deny coverage or benefits to certain groups based on biased or inaccurate future estimation. | (P3) "say for example, mapping poverty or any type of aid allocation, you're trying to get some sort of aid to the most vulnerable people. Of course, your models are going to be imperfect, and just by being imperfect you could argue you're creating some indirect harm because you didn't perfectly identify the most vulnerable people, and so the aid was not perfectly used. You could argue that that's harm" (P9) "if a forecast is showing there's not sufficient market or the alternative where a forecast might be overly optimistic in terms of what that market could be and then it doesn't materialise. And then a manufacturer may lose interest in that market and no longer trust forecasts that come through or choose to no longer invest in something which could be – right, it could go either way in terms of that risk of over promising on a market opportunity and causing investment versus, or even – or not making that investment because it doesn't seem like there's the market potential" (P9) "the harm is people not having access to life saving products. So that if you have an opportunity to bring a product to market, but forecasts are saying, OK. That's actually not going to – instead of then identifying what are the challenges? Is it an affordability issue? Is it something we can work on to make this product which may have need or demand or promise, but we're not seeing it? It's then disallowing access to something which could be a life or health improving product." (P3) "we try to identify regions that are in biggest need of help. If we get that wrong, so that through the inefficiencies can lead to harm that maybe if we miss the most vulnerable people and we send resources to people who are actually better off, then indirect through the failure to help the most vulnerable we are causing harm" (P3) "we're trying to map population displacement. Again, we are doing this of course with the aim of facilitating aid and having a better humanitarian response. But you could imagine th |

| | refers to the missed opportunities for investement when inaccurate forecasts lead businesses to overestimate or underestimate market demand. | (P9) "if a manufacturer over produces a product and then the demand does not materialise based on what was seen in the forecast, they then lose – potentially. I mean, the risk goes wide. They could either lose confidence in the market and then not choose to invest in a product with public health promise or applicability in the future. Or, in some instances, what we've seen with smaller companies, it's a risk to their viability in terms of even being in business and being able to provide products to especially a market that's dependent on more affordable products that some of the less sophisticated, less well financed organisations produce. (P13) "the harm is people not having access to life-saving products, right? So if you have an opportunity to bring a product to market, but forecasts are saying, "OK, that's actually not going to' instead of then identifying, you know, "What are the challenges? Is it an affordability issue? Is it something we can work on to make this product." (P9) "Because if a forecast is showing there's not sufficient market or the alternative where a forecast might be overly optimistic in terms of what that market could be and then it doesn't materialise. And then a manufacturer may lose interest in that market and no longer trust forecasts that come through or choose to no longer invest in something which could be – right, it could go either way in terms of that risk of over promising on a market opportunity and causing investment versus, or even – or not making that investment because it doesn't seem like there's the market potential" (P2) "Td like to go back one thing; here's one more thing where forecasting can cause harm. If the forecaster has just gone to the ISF and published his wonderful new forecasting method that improved the [mape? 00:21:30] by .2 per cent by building a huge giant boosted transformer neural recurrent network, and then somebody implements that, and it does indeed improve forecasts accuracy, but the business outcome is the same as |

|---|--|---|
| Technology may supplant the use of paid human expertise or labor. | Automated forecasting systems may replace human expertise, leading to a devaluation of professional judgment and reducing opportunities for human oversight and intervention. | (P1) "Spending a lot of time forecasting things that don't require anything mothan a [unintelligible 00:33:22] forecast." (P2) "T m not saying that this is a consequence of bad forecasts but that can be consequence of bad forecasts. And that is a type of harm. That was not the har of throwing stuff away, that was the harm of locations closing, people not bein able to shop there anymore, investors in the company losing their money. So this could all be a harm comin from bad forecasts." (P3) "If we get that wrong, so that through the inefficiencies can lead to harm that maybe if we miss the most vulnerable people and we send resources to people who are actually better off, then indirect through the failure to help the most vulnerable we are causing harm." (P4) "And if you lift the lockdowns too carly you then see the disease activity you were trying to prevent. So you've had all of the incidental harm of your intervention and you've lost any potential gain. So that was absolutely the most acute period where a real mistake in the forecast that said, yes, we should people or yes we should relax some of the restrictions too early, but, yes, we would hav gone through a very long, difficult time with very broad societal impact and the thrown away most if or if not all of what we would've hoped to achieved with that." (P5) "If you're right, that's great; if you're wrong that means the emergency hapapened somewhere else and all your stuff was in the wrong place and so the was that additional cost potentially in human suffering and loss of life in gettir those resources to where they actually needed to be as opposed to where you though they were going to be." (P6) "Often the difference in accuracy of using a simple method and a highly sophisticated on is quite small and not of concern. I think forecasts need to be made independingly vested interest." (P7) "As a consequence, there were huge issues with financial and environment implications of all this excess |

Denial of consequential services / Economic loss / Devaluation of individual expertise

(15) "Often, I think you try to use it, but if it's significant excess, then of course, to your point, expiry date comes into play. That's why we just often end up destroying it and that then leads to, as you mentioned also, environmental impact as well."
(17) "Some companies might actually have to then get to lay-offs and to really reconsider their business."
(20) "So if folks were to use our forecast potentially in an uninformed way, it could lead to real harm so we just overbuy on the wrong stuff. But the biggest concern definitely is economically."

| Description in Miscrosoft | Description adapted to forecasting | Quotes from interviews |
|---------------------------|--|--|
| | Forecasts can lead to unnecessary expenditures, wasted time, misallocation of resources, and misguided decision-making. | (P6) "a major harm – the easiest one to identify is the misdirection of resources as a result of inaccuracy. And so if we can minimise the inaccuracy of forecasts we can minimis harm. So a lot of harm comes from inaccuracy in addition. So let's take stage one which is identifying a decision that requires a forecast. Well, in many companies I've been in people confuse forecasts with decisions and they confuse them with many other things as well." (P6) "Construction projects I've mentioned where there's a great maldistribution of resources as a result of inaccurate forecasts." (P6) "if a forecast is inaccurate, and I think much inaccuracy is avoidable, it can lead to a misdirection of resources. So for example if a forecast is based on inappropriate methods or if judgemental forecast is input into the process and they suffer from cognitive biases like optimism bias or indeed the planning fallacy. You can talk about that later if you like. Or particularly motivational biases like sandbagging where you deliberately keep your forecast low, so you'll look good if that forecast is exceeded for example. If these forecasts are published there could be a misdirection of resources." (P6) "Obviously weather forecasts being wrong, forecasting hurricanes when they don't occur can create great inconvenience to people. Mass evacuations. Not forecasting when they do occur, I think New Orleans may have been an example of that during the Bush administration, can cause tremendous harm because people aren't equipped or ready to evacuate when a hurricane appears." (P1) "Spending a lot of time forecasting things that don't require anything more than a [unintelligible 00:33:22] forecast. I mean it's mostly being efficient in our activities and not waste our time, so basically chasing mice in my example. And it appears that in fact there's a lot of forecast where [unintelligible 00:33:47] forecast has two units errors, and when you buy your pack size is 50 units, I mean two units won't chang |

|---------------------------|---|---|
| | Highlights the significant financial loss businesses and users may face | (P2) "I need to drive farther away to find a different store where I can buy my stuff. And that is simply an economical cost because you have to drive longer, I have to spend more on gas and stuff like that" |

(P9) "I think another example is what I alluded to previously of forecasts that have come out under one set of conditions, and I'm thinking of a specific product and a small supplier or manufacturer in China who was developing a product. They worked really hard to get through their processes to get the right quality assurance for their product, to get it registered in markets. Forecasts were developed under one set of circumstances and one set of assumptions, and then they made decisions around setting up their production in line with those forecasts. And then the circumstances changes and those volumes didn't materialise, and they then really felt somewhat betrayed by the donor community and by feeling like they'd done their part. So that's more of the like trust, and then wanting to engage with this public health community moving forward and then feeling – I assume it had detrimental affects to their business as well."

(P20) "if folks were to use our forecast potentially in an uninformed way, it could lead to environmental harm so we just overbuy on the wrong stuff. But the biggest concern definitely is economically. Again, in the example that I have, in pricing, we forecast prices at all kinds of different discount levels. So if you want to use our forecasts, you have to know what the prices are going to be for it. You have to have a notion of the likelihood of a price and if you assumed a too opIntervieweeistic scenario where we discount too high or discount too low, then that could lead to a substantial financial harm for the company" (P4) "if you do it too early you've gone through all of the economic harm, the mental health and wellbeing harm, the impact on medical services beyond COVID-19 such as surgeries and so on, all of these wide-ranging societal impacts. And if you lift the lockdowns too early you then see the disease activity you were trying to prevent. So you've had all of the incidental harm of your intervention and you've lost any potential gain. So that was absolutely the most acute period where a real mistake in the forecast that said, yes, we should open, or yes we should relax some of the restrictions too early, but, yes, we would have gone through a very long, difficult time with very broad societal impact and then

thrown away most if or if not all of what we would've hoped to achieved with that" (P7) "If you're concerned about keeping your customers happy and fulfilling

orders and you have a forecast that either underestimates what that demand is likely to be or you don't make decisions to [unintelligible 00:14:03] a proper inventory, you risk that failing to fulfil orders. There's potential of some loss of revenue there if there's not a substitute product that they're willing to buy. And potential long-term of losing customers who don't find you as a trustworthy supplier for their demand."

(P18) "It is the economical loss again, yeah. Investments take place, we make purchases, we buy inventories and then because the forecasting is inaccurate, those investments are wasted and the company needs to take different actions to deplete that."

(P9) "Like thinking of manufacturers in China that have had issues with being told that they were – you know, they went through a process to get WHO prequalification, they've invested in this product, they've really worked to get to a price point that should be affordable. And then geared up their production and then invested in making those products available, and then if the demand doesn't materialise that's a risk to their business and a risk to the future of this product." (P1) "Not making the right decisions which leads to operational issues which lead to economical impacts"

(P18) "some forecasting took place at Meta for infrastructure capacity planning and there was a lot of investment in a certain type of, say, computer, a machine, a server. And then the forecasts were not accurate and we did not necessarily realise those forecasts. So, the amount of investment that we had was exceeding the demand significantly. And then we realised that huge gap, what we had was a lot of machines lying around, basically cannot be leveraged in for some other purposes. We are talking about billions of investments. So those servers, even today, we couldn't find a way to leverage them. Idle resources, the investment is done and still today we are looking for how to use it because there is no other way for Meta to use these type of machines, a very specific example. (P17) "that's the economic harm really, I think, of the forecast. If I summarise, although I went a bit into the extent of the whole process here, but then we would be missing sales or we would have huge inventory costs."

(P20) "the forecasts at very high discount levels are very inaccurate. It's even hard to say if they're inaccurate but the uncertainty is very large. So if you consume our forecasts, if you just take a point forecast from those very high discount regimes where we have a lot of uncertainty and you build, let's say, an inventory control mechanism for it, and this actually happened, then that can lead to substantial harm, financial loss."

(P17) "They kept on forecasting high, high, high and then the demand wasn't there anymore. There are some companies that have massive write-offs because their inventory is huge, and after expiry date, well what can they do? They're not going to sell it anymore. Those write-offs, if they're big enough, can really, really cause big harm economically for companies, and some companies might actually have to then get to lay-offs and to really reconsider their business."

(P2) "they went out of business because – or partly because – they had issues with their on shelf availability, and people were not able to buy their stuff. I'm not saying that this is a consequence of bad forecasts but that can be a

consequence of bad forecasts. And that is a type of harm. That was not the harm of throwing stuff away, that was the harm of locations closing, people not being able to shop there anymore, investors in the company losing their money, people working at the company losing their money. So this could all be a harm coming from bad forecasts."

(P11) "think of Shapley or what have you for machine learning, right, so that you can get an idea of what happened. What kind of input would have been driving certain outputs? If you don't have that, it's going to be very risky to implement it, because at some point in time you're going to get that one blow up and not know why it happened and if it's going to happen again."

(P18) " we basically plan for lots of inventory needs but then we don't necessarily see a demand and then that additional inventory, first it is a financial burden to the organisation. So much money is left."

(P12) " without the proper context, people can overreact or underreact to that signal, is what's going to happen. With any overreaction or underreaction, you have the capability of not servicing the customer, which could have devastating consequences to it, or you could overreact and end up with way too much inventory. You're going to have cost and cash issues, potential issues with those that could impact your margin, it can impact cashflow"

| This means exploiting personal preferences or patterns of behavior to induce a desired reaction. | Forecasts based on behavioral patterns might exploit personal habits, nudging stakeholders into decisions that align with the model's predictions rather than their actual best interests. | (P4) "So I am aware of people who use any messaging, be it forecasts or just random voices in the media or, yes, media coverage of a single high profile thing such as, say, a child being hospitalised or put into an intensive care unit. They will use that to drum up or to help sell the message of you should get vaccinated And I am aware of a few people in this space that push vaccination and see anything that supports the idea that there's going to be a lot of disease is an acceptable means of trying to convince more of your population to get vaccinated regardless of how ill-founded or incorrect, say, the forecasts or the data or your messages are." (P6) "The fourth thing, I think, is what I call the self-destructive forecast. In many domains, when you make a forecast it actually changes the thing you're trying to forecast." (P6) "The fourth thing, I think, is what I call the self-destructive forecast. In many domains, when you make a forecast it actually changes the thing you're trying to forecast." (P6) "The fourth thing, I think, is what I call the self-destructive forecast. In many domains, when you make a forecast it actually changes the thing you're trying to forecast. I mean, a classic thing is opinion polls where you forecast that one party is going to win an election and voters decide not to bother voting, 'Oh well they're going to win by a landslide. There's no point in turning out.' They don't vote. The forecast turns out to be wrong, and this happened in the 1970 election, well before you were born I'm sure, in Britian where Harold Wilson's Labour government were looking for a landslide. Lovely summer's day, Labour voters didn't bother to vote, and Edward Heath won the election. I think because of this, opinion poll forecasts have been banned apparently in lots of different countries because of their danger of influencing the electorate, and possibly damaging democracy. So the damage can be to democracy." (P6) "Opinion polls which arguably damage democracy |

Erosion of social & democratic structures / Manipulation / Behavioral exploitation

(P19) "I haven't mentioned election forecasting. It's a timely reminder that people can then choose not to vote because they think they can. And Brexit is sometimes used as an example. I don't know whether it is an example or not, but sometimes used, that people believe that the vote for Brexit, against Brexit was straightforwardly won and didn't vote and therefore, I don't know. There may be some evidence about that. So, yes, there are clearly potential negative consequences from trusting, putting 100

(P1) "in France, for example, people tend - there's very few people going to vote. Most people are not doing that, or they don't care, and/or they vote blank, not to ... And so in fact there's very few people that make the decisions. So a little change; it was very few people could change the final outcome. And when the vote forecast are published, sometimes they say, 'Oh it's very, very close and we don't know who's going to win,' so basically we - that's - it doesn't change the way I think people act, or maybe they could change the way they act. But sometimes they say, 'OK, this candidate, this guy, is going to win with a very large advance.' And then people in his electoral side say, 'OK, why should I go voting? I'd rather go to the restaurant, or go on vacation, or whatsoever, but I'm not going to vote because it won't change anything. It's already a win.' So people tend to think that OK, everything is already OK, clear. I could basically discard this, making any decision, it's already done. And because of that, the candidate is losing because a lot of people made this decision, this assumption, and it changed the way people acted. Or maybe the candidate himself changed his behaviour and said, 'OK, it's going to be ... ' And because of that, he feels more relaxed [laughs] and is not fighting up to the end."
