Artificial intelligence contribution to translation industry: looking back and forward

Mohammed Q. Shormani,

Department of English Studies, Ibb University, Ibb, Yemen Department of English Studies, University of Cyprus, Nicosia, Cyprus Email: <u>shormani.mohammed@ucy.ac.cy</u> Orcid: <u>https://orcid.org/0000-0002-0138-4793</u>

Abstract

This study provides a comprehensive analysis of artificial intelligence (AI) contribution to translation industry (ACTI) research, synthesizing it over forty-five years from 1980-2024. 13220 articles were retrieved from three sources, namely WoS, Scopus, and Lens. We provided two types of analysis, viz., scientometric and thematic, focusing on cluster, subject categories, keywords, burstness, centrality and research centers as for the former. For the latter, we thematically review 18 articles, selected purposefully from the articles involved, centering on purpose, approach, findings, and contribution to ACTI future directions. The findings reveal that in the past AI contribution to translation industry was not rigorous, resulting in rule-based machine translation and statistical machine translation whose output was not satisfactory. However, the more AI develops, the more machine translation develops, incorporating Neural Networking Algorithms and (Deep) Language Learning Models like ChatGPT whose translation output has developed considerably. However, much rigorous research is still needed to overcome several problems encountering translation industry, specifically concerning low-source languages, multi-dialectical and free word order languages, and cultural and religious registers.

Keywords: Artificial intelligence, translation industry, machine translation, Neural Algorithms, Language Learning Models, ChatGPT, scientometrics

1. Introduction

The present time is an era of artificial intelligence (AI) par excellence, which has witnessed tremendous developments. AI started shaping its foundations in 1955 (Minsky, 1961; Turing, 1950). AI refers to creating, modeling and/or producing computer intelligence like human. It is the development of computer models that can perform tasks like human intelligence. These computer models involve algorithms trained on large datasets to learn patterns and make predictions (McShane & Nirenburg, 2021). AI aims to simulate intelligent behavior including learning, problem-solving, perception, and even decision-making (Liao et al., 2018). These models are reported to perform tasks with considerable accuracy (Linzen & Baroni, 2021; Gulordava et al., 2018). The great revolution led by AI generative models depends on the use of the NNAs (Peng et al., 2023). These algorithms have been utilized in all AI models; their working mechanism functions like human brain. Translation industry is no exception; AI has revolutionized the translation industry in many and several aspects. There are several AI translation applications such as Google Translate, DeepL, Babylon, WordLingo, ChatGPT and numerous other smartphone apps. These translation applications have also been developed and improved considerably (Shormani, 2024b).

Scientometrics is considered one of the modern tools to provide invaluable insights into how research in a field of study develops, demarcating the strengths and weaknesses, knowledge gaps and future directions. It is defined as "the study of the quantitative

aspects of science and technology seen as a process of communication", used across a wide range of research areas including scientific and social sciences and humanities disciplines (Mingers & Leydesdorff, 2015, p. 1). It has been used extensively in characterizing such trends utilizing statistics, mathematics, software-generating visualization devices to conceptualize and concretize the achievement of scientific research. It covers a wide range of disciplines to find out to what extent a particular field of knowledge has achieved distribution and how the scientific community has engaged in this field (Geng et al., 2024). Recently, two influential software have been developed, namely CiteSpace and VOSviewer, which are used to conduct such types of scientometric studies, covering a wide range of disciplines including scientific and social sciences.

In this study, we provide a comprehensive analysis of the AI contribution to translation (ACTI) research in a period spanning more than four decades, investigating its beginnings, developments over time, and unveiling the current intellectual landscape, (re)emergent trends and hotspots. To the best of our knowledge, no previous study has tackled this phenomenon, hence this study serves to fill this gap. The study depends on bibliometric indicators available in WoS, Scopus, and Lens including authorship, affiliation, article title, keywords, cited and citing references, cited reference count, publication year, country, and language, utilizing two programs: CiteSpace 6.3.1R (https://citespace.podia.com/), and VOSviewer (https://www.vosviewer.com/) to analyze and generate mapping visualizations of ACTI research. Our analysis employs cluster analysis, burstness, (betweenness) centrality, subject categories, and keywords. These metric indicators unveil ACTI intellectual landscape, trending issues and hotspots, demarcating the strengths and weaknesses of ACTI research, and pinpointing the possible knowledge gaps. These scientometric analyses were followed by a thematic analysis of 18 articles carefully chosen based on two criteria, namely the most citing articles and experimental articles relating to AI, CL and NLP, that provide valuable insights into how MT could be developed to overcome the existing problems.

Thus, our purpose in this article is to examine AI contribution to translation industry, looking back and forward, answering questions such as when did MT start?, what is the intersection of AI and MT?, how has AI developed it?, how has scholarly community approached MT?, and what are the future frontiers of this area of study? The rest of article is as follows. In section 2, we articulate the literature review, handling studies on ACTI. In section 3, we spell out the study methods, distilling our data sources, data screening, and methods of analysis. In section 4, we analyze the results and in section 5 we discuss these results. In section 6, we conclude the article, leveraging the future frontiers of ACTI.

2. Literature review

2.1. artificial intelligence

The contribution of artificial intelligence to translation industry goes beyond one research article, as AI accelerates translation, contributing to its success, shaping its boarders and making it successful ever before, though problems arise now and then concerning some typological differences between languages. AI could be considered the bases on which Machine Translation (MT) feeds and lives. Through AI, translation has entered a new world, a technological world. It has witnessed a huge shift from just a human endeavor to a "computer" craft, due mainly to the tremendous developments technology, internet and AI have undergone. There are hundreds of smartphone

applications developed for translation. This is all due to the involvement of AI in translation industry. In the current time, translation depends on Computer Assisted Translation (CAT) tools, and the human role becomes limited to just postediting, if any. AI involvement in translation industry results in several web apps including Google Translate, and Microsoft Translate, which are basically Statistical Machine Translation (SMT) devices (see e.g. Farzi & Faili, 2015). With the advancements of AI technology, Neural Networking Algorithms (NNAs) dramatically change AI orientations leading to launching several Language Learning Models (LLMs), the most powerful of which is ChatGPT. As for translation, ChatGPT can translate massive amounts of data from any language into another in seconds, performing competitively better than any CAT tool, specifically ChatGPT-4, as a result of the huge amounts of internet data ChatGPT has been trained on (Kung et al., 2023; Larroyed, 2023).

ChatGPT is one of AI generative models, developed by OpenAI mainly for translation purposes, but "can generate content across various domains, such as text, images, music, and more" (Ray, 2023, p. 121). It has not only impacted these aspects, but also leveraged the "scientific research, spanning from data processing and hypothesis generation to collaboration and public outreach" Ray, 2023, p. 121). ChatGPT is an example of large language models, a deep learning model that is designed for generating translations much more accurate than other CAT tools such as Google Translate (Lee, 2023; van Dis et al., 2023). In other words, ChatGPT has been reported to perform competitive translation tasks better than any other CAT tool. ChatGPT is one of these developments; ChatGPT has been developed mainly for translation. However, it has been used for several purposes and in several fields including summarizing, bugging, creating content, completing codes, and automated tagging (see e.g. Kung et al., 2023; Kenny, 2022; Lee, 2023; Ray, 2023; Siu, 2023; Shormani, 2024b).

2.2. Machine Translation

Translation is viewed as a human activity; it is also a process in which our knowledge, experiences, and ideologies are transmitted from generation to another (James, 2002; Shormani, 2020, 2024b). Translation is not limited to just transferring the meaning of a text wording, but it involves creativity and innovation (Dugonik et al., 2019). MT has been one of the major concerns of AI, Computational Linguistics (CL) and Natural Language Processing (NLP) specialists, involving linguistic texts that can be produced and read by computer, and employing "methods for extracting linguistically valuable information from such texts" (Brown et al., 1993, p. 263). It has developed considerably, specifically recently. It started with employing rule-based mechanism, then statistics, and finally NNAs, coming up with several types (de Coster et al., 2023), and reflecting the stages it has passed through in each of these types. There are several spheres of MT including TV and film industry like subtitling, dubbing, subtitling, and lexigraphy and dictionaries, and large amounts of documents can be translated in a short time (Fernández-Costales et al., 2023; Zhang & Torres-Hostench, 2022).

It is estimated that MT history spans four centuries now, referring to René Descartes in 1629 who held that what can be expressed in a language can be expressed in another language sharing one symbol (Yang et al., 2020). However, the actual beginning of MT as a field was in 1960s, recommended by several scholars in the first International Conference on Machine Translation in 1952 (Forcada et al., 2011). SMT started as translating single/isolated words, but since then it has developed to include phrases and

sentences. MT has witnessed tremendous developments since then shaping its frontiers into three types: Rule-based Machine Translation (RMT), Statistical Machine Translation, and Neural Machine Translation (NMT) (Koehn et al., 2003; Forcada et al., 2011).

The main idea of RMT is that a word in L1 can have an equivalent in L2. In this sense, what MT does is replace L1 word with L2 word in a syntactic-based manner. However, languages differ in the way syntax works in each language. Put simply, languages such English follow an SVO word order, but languages like Arabic follow a VSO word order. Additionally, English, for instance, is a head -first language, while languages like Hindi are head-last languages. These syntactic and typological variations were not easy to master by machine (precisely computers), and hence MT output was not always satisfactory. Another problem encountering RMT was semantic in nature. For example, polysemy, which means a word can have several meanings in L1, may not be possible to be captured by RMT.

RMT's drawbacks were the starting point to think of an alternative, which is SMT. SMT's main idea is that a word can have multiple meanings and computers just identify the best match from a bilingual corpus based on statistics. The bilingual corpus could be thought of as a bilingual lexicon, WordNet is the best example. This idea is behind Google Translate working mechanism, where machines identify the best match/meaning of a word in L1 from L2 as they are iterated in the bilingual corpus. SMT moves translation far strides, underscoring the translation industry, and researching it spanned a long time till today. Several SMT models have been developed, and scientists and scholars keep improving it, as will be clear in the review in Table 6. However, SMT produced translation were also not satisfactory as can be seen in Google Translate output. And with the tremendous developments of technology and AI, MT enters a new world, the best manifestation of which is incorporating neural algorithms, or deep language learning networks. This results in what is known as neural machine translation, which will be the focus of the section to follow:

NMT is mainly based on NNAs, ascribed to the huge developments taking place in AI technology (Peng et al., 2023). These ideas started to crystallize in the early 1990s, where "intelligence" invaded computer industry (Pollack, 1990). The main idea is how to make computers think or do tasks like humans. However, the starting point of NNAs started in about 2010 with the advent of Deep Learning Language Models (DLLMs). Several DLLMs have been developed including hybrid models based on SMT and NMT (Dugonik et al., 2019), multi-NMT models (Huang et al., 2023), a transformer model (Baniata et al., 2021), human-postediting model (Formiga et al. (2015), and AI-human models (Li et al., 2023). With the help of NLP and AI, NMT has been a surge in translation industry, attracting ample scholars and researchers from linguistics, computer science, technology, computer engineering, programing, CL, and NLP. The most recent development in this regard is ChatGPT, the purpose of launching which was translation, but eventually it has been used for many and various purposes, as we have discussed so far.

3. Methods

3.1. Search strategies and terms

The main search strategy we adopted in data collection was done in two phases: phase one was concerned with setting the timespan in Web of Science (WoS) search engine. The timespan was set to 1980-2024. In WoS, we could not find publications concerning

AI and Translation before that time. Table 1 summarizes search query and terms, results and the data retrieved.

Query	Search type	Research terms (Searched on April 2, 2024)	Lens	Scopus	WoS	Total
nonspecific	Title- AB-KW	Artificial intelligence" OR "Computer" OR "Machine Translation" OR "Neural Algorithms" OR "Neural Networks" OR Computational Linguistics" OR "ChatGPT" AND "Translation" OR "Postediting" OR "Human Translation"	6016	1219	5332	12567
	Limits. & excld. Data	(LIMIT-TO (LANGUAGE, "English")) AND (EXCLUDE (NONRESEARCH- ARTICLES)))				
specific	Title	Artificial intelligence" OR "Computer" OR "Machine Translation" OR "Neural Algorithms" OR "Neural Networks" OR Computational Linguistics" OR "ChatGPT" AND "Translation" OR "Postediting" OR "Human Translation"	338	173	142	653
	Limits. & excld. Data	(LIMIT-TO (LANGUAGE, "English")) AND (EXCLUDE (NONARTICLES)))				
Total			6354	1392	5474	13220

 Table 1: Query, search types, search terms across Lens, Scopus and WoS

3.2. Data screening

The search strategies result in 13220 in total. We used CiteSpace and Mendeley to remove duplicates. The removal process results in 9836 unique records and 3384 duplicate records. Nonarticles include meeting abstracts, enriched cited references, book reviews, review articles, editorial materials, open publisher-invited review, retracted publications, corrections, letter, and notes.

3.3. Data export and conversion

The nature of our data is multi-sourced, viz., WoS, Scopus, and Lens. These three sources each have different file format to export the data. So our data were exported in various formats as displayed in Table 2.

Table 2: Data source, file format, analysis and software used

Data source	Export Format	Analysis	Software used
Lens	CSV	Bibliometric Analysis	VOSviewer/ CiteSpace
Scopus	CSV	Bibliometric Analysis	VOSviewer/ CiteSpace
WoS	Endnote Desktop	Bibliometric & Scientometric Analyses	CiteSpace/ VOSviewer

After exporting our data, we used CiteSpace algorithms to convert Lens and Scopus data to WoS-to-be-processed data. After the conversion process, the data were compiled in one folder for CiteSpace output analysis.

3.4. Methods of analysis

We use two methods to analyze our data, scientometric analysis and thematic analysis of ACTI research in forty-five years. The former concerns analyzing Cluster/trend, Betweenness Centrality, Burstness, and Silhouette. Both CiteSpace and VOSviewer were used for these types of analysis. Thematic analysis involves analyzing some articles, carefully selected from the articles involved in our study. They were chosen considering the cluster analysis, precisely from the major citing articles of each cluster, in addition to considering other analyses such as Subject Categories, Keywords, and Bursts, coming up with 18 articles.

4. Results

4.1. Cluster analysis

Cluster analysis represents ACTI research knowledge production, trends and hotspots. There are 471 research trends in our study as generated by CiteSpace, but we modified CiteSpace settings to visualize only 12 top clusters.

ClusterII	D Label (LLR)	Size	Silhouette	Average
				Year
4	small parallel corpora	76	0.988	2004
13	wide-coverage multilingual semantic network	19	0.987	2009
3	statistical machine translation	95	0.974	2011
8	machine translation	39	0.971	2011
2	neural machine translation	100	0.914	2016
6	deep learning	48	0.941	2016
0	generative adversarial network	125	0.96	2017
1	low-resource language	117	0.883	2018
5	large language model	49	0.945	2020
15	arabic dialects	16	0.988	2020
7	deep neural network	40	0.979	2021
14	deep learning models	16	1	2023

Table 3: Cluster analysis in terms of Size, Silhouette LLR and average year

Table 3 showcases Cluster analysis of ACTI research, providing profound insights into how ACTI research develops over forty-five years, uncovering ACTI intellectual landscape and trending issues. The clusters presented in Table 3 are sorted by emergence date (i.e. the average year of emergence). Intellectual landscape of ACTI in forty-five years is represented by the top 12 clusters as displayed in Table 3. Cluster 4 *Small parallel corpora*, emerging around 2004, marks the scholarly community's interest in ACTI research in that time. Having 76 articles and a Silhouette value of 0.998 is prominent, underscoring ACTI specialists' interest in using computer technologies to compose Corpora like *WordNet*. Around 2009, cluster 13 *Wide-coverage multilingual semantic network* comes to play, constituting a trending issue in ACTI research, though having 19 articles. Cluster 3 *Statistical machine translation* evolves around 2011, preceding *Machine translation* (Cluster 3), which evolves around 2011, in the same year. Although MT began to take shape in 1960, machine translation in our corpus comes to play around 2011, thus mirroring the research focus of ACTI scholars.

Neural machine translation (Cluster 2), with size of 100 articles and a Silhouette value of 0.914, appears with a 5-yeat gap after *statistical machine translation*, reflecting the actual time sequence of their entrance in the history and field of MT. *Deep learning* (Cluster 6) began to take shape around 2016, hence representing a trending issue in ACTI research in that period, and reflecting scholarly community's focus in that time. *Generative adversarial network* (Cluster 0) is considered the top prominent trending issue in ACTI research during forty-five years, having 125 articles and a Silhouette value of 0.96. Around 2018, a new trending issue, i.e. *low-resource language*, marks a shift in ACTI research, reflecting new interest. *Large language model* (Cluster 5) with 49 articles and a Silhouette value of 0.883, again marks the sequence of development in MT industry and AI in general.

The three last clusters, namely *Arabic dialects, deep language model,* and *deep learning models* evolve around 2020, 2021 and 2023, respectively, demarcating ACTI research focus in these periods. As we proceed, we will see when each of these trending issues was constituted and how long its strength lasts when we analyze the strongest bursts of most of these hotspot issues.

4.2. Burstness

Burstness in scientometric analysis refers to a frequency surge of a citation of an article in particular period of time (Chen, 2006; Ballouket al., 2024). In what follows, we devote a space to discussing subject categories and author's keywords in terms of burstness.

4.2.1. Subject categories

During forty-five years, ACTI research has witnessed tremendous developments starting from RMT, SMT, NMT, utilizing several web apps such as Google Translate, Microsoft Translate, and finally DLMs such as ChatGPT. It has also interacted with and been contributed to by several areas including language/linguistics, computer science, physics, and artificial intelligence, resulting in many and various research areas, application models such as devising semantic networks, small corpora, software engineering, and ChatGPT. All these moves in ACTI research lead to several attempts to seek answers to several questions: i) is it possible to apply these developments across languages like Arabic, Spanish, Chinese, ii) what is the reality of the resultant translations by applying ACTI technologies and discoveries, and iii) do MT's translation products need human role, and if so, to what extent? These questions, among others, are currently leading ACTI research worldwide. However, each question arises in a different time as showcased by "year" in Fig 1, demarcating scholarly community ACTI research orientations and interests in finding out answers to each question in (iiii), as indicated by the beginning of the burst period, and mapping out when scholarly community's interest/research focus moves from one question to another, as revealed by the ending period of bursts.

Top 10 Subject Categories with the Strongest Citation Bursts

Fig 1: Top 10 subject categories with the Strongest Citation Bursts

4.2.2. Keywords

Fig 2 presents the top used author's keywords based on the strongest citation bursts in ACTI research for forty-five years. *Statistical machine translation*, unveiling strong focus on ACTI. It emerges around 1999, ranking first with 55.24 strength beginning in 2003 and ending in 2019, and lasting about 16 years. *Information retrieval* emerges in 1997 with strongest burst of 17.96 lasting for 22 years, from 1997 to 2019. Then the focus moves to *support vector machine* which emerges as a keyword in 2006, the strength of which lasts about 13 years from 2006 to 2018. *Translation quality* maps out the important focus on how translation should be, demarcating this interest for 8 years, 2011-2019. *Target language*, as a key focus word in ACTI research, with burst strength 15.15 lasts over 19 years, 1998-2016, underscoring the importance of target language in the translation process. The top 10 keywords end with *cross-language information retrieval* with burst strength of 12.37, emerging in 1998, and spanning from 1998 to 2014.

Top 10 Keywords with the Strongest Citation Bursts

Fig 2: Top 10 keywords with the Strongest Citation Bursts

For a full picture of keywords, consider Fig 3 displaying keywords' density view generated by VOSviewer.

4.2.3. Top nodes by bursts

Table 4 presents the most important nodes by bursts in ACTI research during fort-one years. Statistical machine translation is the top ranked item by burstness in Cluster 1, with burst of 56.52, beginning in 1999, and highlighting ACTI research during 2003-2019. The 2nd is *information retrieval*, Cluster 0, with burst of 17.09 marking a stage of ACTI research, and ensuring that information retrieval precedes SMT, which perhaps indicates a stage of developing programs to be used in SMT. The 3rd is *translation* quality in Cluster 1, with burst of 16.25, accelerating the need of good translation and pinpointing the bad quality of MT output. The 4th is *target language* in Cluster 8, with bursts of 15.38. This keyword represents a search area in ACTI, manifesting that TL should be paid much attention to. The 5th is new approach, Cluster 1, with burst of 15.13, indicating perhaps a change towards a new approach in MT industry. The 6th is support vector machine in Cluster 7, with bursts of 14.74. The 7th is machine translation system, Cluster 1, with burst of 13.02. The 8th is cross-language information retrieval in Cluster 0, with burst of 12.40. The 9th is parallel corpora in Cluster 1, with burst of 11.52. The 10th is *transformers* in Cluster 2, with burst of 11.00. Notice that almost all top 10 nodes by bursts iterate in our previous analyses. This gives us a room to postulate that our analysis is reliable and valid.

Table 4: 1	Fop nodes	by Bursts
------------	-----------	-----------

Bursts	Node Name	Cluster ID
56.52	statistical machine translation	1
17.09	information retrieval	0
16.25	translation quality	1
15.38	target language	8
15.13	artificial intelligence	1
14.74	support vector machine	7
13.02	machine translation system	1
12.40	cross-language information retrieval	0
11.52	parallel corpora	1

11.00 transformers

In scientometric analysis, centrality reflects the likelihood of an arbitrary shortest path in the network. It is also regarded as a position *between* two large sub-networks (Chen, 2006; Ballouket al., 2024). Table 5 showcases the top ranked nodes by centrality in ACTI research during forty-five years. The 1st is *machine translation* in Cluster 0, with centrality of 0.27. The 2nd one is *novel approach* in Cluster 13, with centrality of 0.07. The 3rd is *artificial intelligence* in Cluster 3, with centrality of 0.07. The 4th is *machine learning* in Cluster 0, with centrality of 0.06. The 5th is *logic programming* in Cluster 6, with centrality of 0.06. The 6th is *statistical machine translation* in Cluster 1, with centrality of 0.05. The 7th is *target language* in Cluster 8, with centrality of 0.05. The 8th is *natural language processing* in Cluster 0, with centrality of 0.05. The 9th is *chatgpt* in Cluster 14, with centrality of 0.05. ChatGPT has been reported to perform competitively better than other CAT tools like Google Translate, specifically, with GPT-4 (Jiao et al., 2023). The 10th top node by centrality is *support vector machine* in Cluster 7, with centrality of 0.05.

2

Centrality	Node Name	Cluster ID
0.27	machine translation	0
0.07	novel approach	13
0.07	artificial intelligence	3
0.06	machine learning	0
0.06	logic programming	6
0.05	statistical machine translation	1
0.05	target language	8
0.05	natural language processing	0
0.05	chatgpt	14
0.05	support vector machine	7

Table 5: Top nodes by Centrality

Again, notice that almost all top nodes by centrality are iterated from previous analyses, be they related to cluster, subject categories, keywords or top nodes by bursts.

Fig 4 portrays the top twelve Research Centers contributing to ACTI in the world, sorted by number of citations. MIT ranks 1st, with 3421 citations and 85 publications. Sandford University ranks 2nd with 2745 citations and 53 publications. The 3rd and 4th ranks are retained by University of California, Berkeley (2427 citations, 30 publications) and Carnegie Mellon University (2393 citations and 51 publications), respectively. The 5th research center is Microsoft Corporation with 1609 citations and 8 publications. The last two research centers are King Saud University and Nanyang Technological University with 1188 citations and 23 publications, and 1180 citations and 18 publications, respectively. Almost all research centers are historically deep rooted in scientific research, specifically computer science and technology, CL and NLP. They belong to USA, Germany, Canada, China, Singapore and one belongs to Arab world, namely Saud Arabia.

Fig 4: Top 12 key research centers in ACTI research

4.3. Thematic analysis

In this section, we focus on reviewing 18 articles related to ACTI, carefully and purposefully chosen from the articles involved in this study. The review is conducted in terms of author, purpose/aim, methodology, findings and contribution to ACTI future directions. The reviewed articles are the most recent publications in our corpus. If there were more than one article in/about a certain topic of ACTI, we consider the most recent one in our data.

The articles reviewed in Table 6 encompass several themes, we have divided our criteria into eight categories: SMT, NMT, Postediting, Linguistics, Language-specific, Hybrid, ChatGPT and Transformer. SMT include two studies, each of which applies AI technology to enhance MT. NMT categories involves four studies. Postediting category reviews a study on involving human postediting. Linguistics include two studies, one involving syntax and the other semantics. Language-specific comprises three studies. In this category, we focused on MT studies centered around specific language pairs such as English and Chinese. Hybrid category has four studies, in which we focused on studies involving both SMT and NMT models. ChatGPT category involves two studies, examining the usefulness of ChatGPT in NMT (Shormani, 2024b). Finally, Transformer includes one study in which the authors develop a transformer model for MT. These 18 articles represent MT research spectrum during forty-five years. Note that there is some sort of overlap in the classification, but we tried to classify the selected articles each in the category it fits more.

Table 6: Thematic review of the literature on ACTI

No	Author(s) +year	Aim/purpose	Approach/methods	Findings	Contribution to ACTI	
1	Formiga et al (2017). Drg/shDI	「前音研究」である「小子子好」では「リレーリンズ」 incorporating human postediting.	Wexed methodology evaluating a real-world dataset collected from Reverso.net	The proposed AI model is robust in automatically Web-crawled parallel corpora. It enhanced SMT translation	The proposed system can be applied to Arabic corpora like Falak (https://falak.ksaa.gov.sa/corpora/ arabiccorpus)	
2	Li et al. (2023)	Comparing conventional SMT with an AI-based translation model to produce high-quality translations.	comparative/experimenta l methodology	conventional SMT achieves 4.9667fluency while AI- based translation model 6.6333.	This AI model can be applied to Arabic mismatchings of L dialects, hence improving ACTI in Arabic context.	
			NMT			
3	Lo (2023)	Improving learners' vocabulary in EFL classrooms by utilizing Neural machine translation:	a quasi-experimental approach	there was no big change in higher proficiency learners' achievement in vocabulary retention. - NMT model proposed help lower proficiency learners achievement in immediate vocabulary retention.	The proposed model can be applied in teaching ACTI in Arabic-speaking classrooms, specifically with low profiency learners.	
4	Belinkov et al. (2020)	analyze the representations learned by NMT models at various levels of granularity and evaluate their quality through relevant extrinsic properties	Experimental methodology focusing on training NMT data	 Word morphology features are simpler than those of non-local syntactic and semantic dependencies Representations learned using full words are more informed than those learned using subword parts. Multilingual LLMs are richer than bilingual ones. 	Multilingual LLMs are more valid than bilingual ones, hence enriching ACTI field.	
5	Huang et al. It enriches NMT providing a AI-based model for Arabic dialects.	the proposed model has been applied to Arabic dialects, hence enhancing ACTI for Arabic dialects.

5. Discussion

This paper synthesizes ACTI research over forty-five years from 1980-2024, considerably a long timeframe aiming to map out the ACTI intellectual landscape and pinpoint the trending issues in this very important area of human knowledge. We have focused our concern on providing analyses of ACTI knowledge landscape and trending issues, represented by clusters, subjects categories, keywords, nodes by bursts and centrality, as scientometric indicators to characterize, visualize and embody ACTI research in this period. Three influential sources the articles were retrieved from are WoS, Lens, and Scopus.

To begin with, in cluster analysis the scientometric analysis gives us profound insights into several factors, the most important of which are: i) a holistic picture of ACTI research intellectual landscape during forty-five years, ii) trending issues in ACTI research, and iii) hotspots in ACTI research. As for (i), CiteSpace identified 471 research trends constituting ACTI knowledge landscape, we discuss only 12 cluster (Table 3). As for (ii), trending issues refer to those clusters representing a high number of publications, CiteSpace dubbed these as "Sizes". Concerning (iii), hotspots are articles that are constituted recently. Thus, the top 12 cluster beginning with *small parallel corpora* and ending in *deep learning models* constitute ACTI knowledge landscape. Clusters such as those having the sizes 125, 117, and 100 could be termed as trending issues, and clusters evolving around 2021-2023 could be called hotspots in

ACTI research over the timespan in our study. We will discuss these and their relevance to ACTI research developments, focusing on (ii) trending issues and (iii) hotspots, each in turn.

ACTI trending issues *generative adversarial network* (Cluster 0), having the highest number of publications, i.e. 125 articles, a Silhouette value of 0.96, and comes to play around 2017. Generative adversarial network (GAN) is a type of LLM, the main idea of which comes from game theory of gain and loss. It is an LLM combined with two neural networks for adversarial training, recently introduced into AI field, specifically deep language learning to produce highly accurate images utilizing deep learning methods in face recognition (Long & Zhang, 2023; Tavakkoli et al. 2020). The importance of this ACTI research trend ensues from utilizing GAN in MT, though it firstly was introduced in face recognition in military field and forensic and legal spheres. It has been employed in natural language processing including MT, thus generating language texts/sentences to overcome CAT translation problems (Ahn et al. 2021).

Low-resource language is another ACTI trend retaining the 2nd rank, i.e. Cluster 1 with 117 research articles and a Silhouette value of 0.883. Low-source languages refer to languages having less data for AI models to process and/or analyze including Irish, Hindi, Bengali, Amharic, Galician, and Basque, that create problems for LLMs. This is due to the fact that these languages do not provide rich data for language processing in machine translation processes, for instance, in the same way high-source languages such as English, Arabic, French, and German do. Low-resource languages thus need certain types of deep learning models capable of processing their poor data. A number of ACTI scholars have attempted to build such models. For example, Goyle et al. (2023) build an NMT model capable of processing *low-resource language* data. Their model was built upon mBART, which seems to achieve promising results helping in amending these languages' problem space.

Statistical machine translation is another trending issue in our study, labelled as cluster 3 in our corpus, coming to existence around 2011, with 94 articles and a Silhouette value of 0.974. SMT has a long history, as one of three stages of MT. It has come after example-based machine translation and developed from it. The first idea of SMT is traced to Brown et al.'s (1990) proposal. In SMT, machines, precisely computers, are trained on a large amount of data to learn translation rules (Wang H. et al. 2022). Since then SMT has developed in several aspects including different models (Brown et al. 1993), a syntax-based model (Yamada & Knight, 2001), alignment template approach (Och & Ney, 2004), shallow linguistic knowledge (Hwang et al., 2007), hierarchical phrase alignment (Watanabe et al., 2007), swarm-inspired re-ranker system (Farzi & Hesham, 2015), SomAgent models (López et al., 2011), syntax-based reordering model (Khalilov & Fonollosa, 2011), and incorporating human postediting (Formiga et al., 2015). However, there have also arisen some studies combining multi-models (Sachdeva et al. 2014), because it was not easy for a single model to meet several translation requirements, which enhances SMT performance. The use SMT perhaps ends when NMT comes to play, which witnesses substantial developments, specifically when employing neural algorithms.

As for ACTI hotspots during forty-five years, three clusters, namely *Arabic dialects, deep neural network* and *deep learning models* are case-in point here. However, we will discuss only two, viz., Arabic dialect and deep learning models. Arabic dialect as a hotspot in ACTI research evolves around 2020, with 16 publications. The entrance of

Arabic language/dialect is very significant due to the fact that Arabic has three major categories/dialects: classical Arabic (CLA), Standard Arabic (SA) and Modern Arabic dialects (MADs). CLA is the language of the Holy Qur'an, it is used in religion-based contexts such as mosques, Islamic teachings, while SA is the official language of Arab States. It is used in such context as press, TV, education, official communications. Finally, MADs are mother tongues of all Arabs. These dialects are used in day-to-day affairs, homes and streets. Undoubtedly, these three varieties of Arabic impose severe problems for MT, be it SMT or NMT. Thus, there are ample studies examining the efficiency of MT for Arabic dialects, accelerating Arabic's peculiarities and properties. For example, Baniata et al. (2021) have introduced a pioneering transformer model that that utilizes subword units for translating Arabic dialects, holding that Arabic dialects constitute a considerable difficulty for NMT as they exbibit free word order.

As for other analyses such as subject categories, keywords, top nodes by bursts and by centrality, it is clear that they are consistent with cluster analysis. Put differently, we notice that almost all the clusters in Table 3 iterate in these analyses, which accelerates the strength, reliability and validity of our analysis. A substantial finding from Table 3 concerns the size of the contribution of AI to translation industry. The fact that *Neural machine translation, Generative adversarial network* and *Low-resource language* having the largest number of articles, viz., 100, 125 and 117, respectively, though emerging around 2016, 2017 and 2018, respectively, compared to *Small parallel corpora,* which emerges around 2004, unveils that in the past AI contribution to translation industry is not rigorous, and that the more AI develops the more its contribution increases.

6. Conclusion and looking forward

With several and various developments AI has undergone, MT has witnessed considerable change and tremendous developments. Through history spanning over than a century or so, MT has undergone tremendous developments, too, beginning with RMT, SMT and ending in NMT and transformers, LLMs and hybrid SMT and NMT models. The study provides a comprehensive scientometric and thematic analyses of ACTI research for a considerably long time spanning between 1980-2024, involving 132220 articles collected from three different sources, viz., WoS, Scopus, and Lens. The scientometric analysis involves cluster, subject categories, keywords, burstness, centrality and research centers. The thematic analysis focuses on reviewing 18 articles, selected purposefully from the top citing and cited articles, centering on purpose, approach, findings, and contribution to ACTI future directions.

Several and various conclusions could be drawn from our study: i) in the past AI contribution to translation industry was not rigorous, resulting in RMT and SMT the translation output of which was not satisfactory. This unsatisfactoriness could be ascribed to many factors, some relating to the undeveloped models used, and some relating to typological parametrizations between languages, ii) with the advent of NNAs and (D)LLMs utilized in MT, MT industry develops considerably, specifically with launching large LLMs such as ChatGPT and several transformers. These AI models have revolutionized almost every aspect of life including academics, education, engineering, scientific research, and MT industry is no exception, and iii) despite all these developments, MT field still needs rigorous research to better MT translation outputs. NMT along with current AI models need to develop further to handle many problems. These problems include those related to low-source languages such as Hindi, Bengali, Amharic, and Irish. Due to the poor linguistic data these languages have,

models developed for them need further research and AI models capable for process their low sources (Goyle et al., 2023).

Another area presenting a real challenge for MT concerns multi-dialectical and free word order languages like Arabic. Due to the diglossic nature of Arabic (see e.g. Ferguson, 1959), we need an AI model capable of handling, processing and computing H and L varieties of Arabic. Arabic, be it CLA, SA, or MAD, has a variety of word orders such as VSO, SVO, SOV, OSV, OVS (Shormani, 2015, 2017, 2024a & b), so we need NMT models that can identify the subject, verb and object in the sentence to translate them correctly (see also Baniata et al., 2021). A further problem encountered by NMT is with regard to register, specifically cultural, and religious registers. As for culture, ChatGPT, though the most powerful AI model, cannot translate an English proverb like The devil is beating his grandma (a proverb said when rain falls and sun shines) into Arabic, as proverbs involve arbitrariness and idiosyncrasies, and are embedded within culture (cf. Shormani, 2020). As for religious texts, ChatGPT, for instance, cannot translate such an Arabic religious text as ابحجر الله 'bi-hajr ?allah!' (=For the sake of God). Thus, what AI-translation programmers and developers should do in this respect is train LLMs like ChatGPT on massive (internet) data that include religious and cultural data to better its performance.
