Abstract

We consider a bilevel learning framework for learning linear operators. In this framework, the learnable parameters are optimized via a loss function that also depends on the minimizer of a convex optimization problem (denoted lower-level problem). We utilize an iterative algorithm called 'piggyback' to compute the gradient of the loss and minimizer of the lower-level problem. Given that the lower-level problem is solved numerically, the loss function and thus its gradient can only be computed inexactly. To estimate the accuracy of the computed hypergradient, we derive an a-posteriori error bound, which provides guides for setting the tolerance for the lower-level problem, as well as the piggyback algorithm. To efficiently solve the upper-level optimization, we also propose an adaptive method for choosing a suitable step-size. To illustrate the proposed method, we consider a few learned regularizer problems, such as training an input-convex neural network.

Keywords: Bilevel Learning, piggyback algorithm, saddle-point problems, Machine Learning, Input-convex neural networks

1 Introduction

Variational image reconstruction has proven to be a successful approach for solving inverse problems in imaging such as image reconstruction. The reconstruction can then be obtained by solving the following minimization problem:

$$
\min_x D(Ax, u) + R_\theta(x). \tag{1}
$$

Here D denotes the data fidelity, R_{θ} is the regularizer, which is parameterized by θ . Moreover, A is a linear operator related to the specific inverse problem of interest, such as image denoising, deblurring or tomography, to name but a few.

Classical approaches rely on hand-crafted regularizers designed to encode prior information about the desired reconstruction. Notable examples include total variation (TV) [\[1\]](#page-12-0), total generalized variation (TGV) [\[2\]](#page-12-1), and sparsity-promoting reg-ularizer [\[3\]](#page-12-2). In these methods, the parameter θ

often corresponds to the regularization parameter, controlling the trade-off between data fidelity and regularization. Various parameter selection strategies have been proposed in the literature, including heuristic approaches like the L-curve method [\[4,](#page-12-3) [5\]](#page-12-4), the discrepancy principle and other a-posteriori rules [\[6,](#page-13-0) [7\]](#page-13-1).

In recent years, data-driven approaches have emerged, enabling learned regularizers to be incorporated into the variational framework [\[8](#page-13-2)[–13\]](#page-13-3). The parameter θ in these methods could represent anything from the coefficients of a sparsifying synthesis dictionary to the parameters of a neural network. One prominent approach for learning parameters in regularizers is bilevel learning [\[14–](#page-13-4) [18\]](#page-13-5). In this framework, given a set of training data pairs $(x_i^*, u_i)_{i=1,\dots,n}$, the goal is to learn the parameters θ by solving the bilevel optimization problem:

$$
\min_{\theta} \frac{1}{n} \sum_{i=1}^{n} \ell(\hat{x}_i(\theta))
$$

$$
\hat{x}_i(\theta) \coloneqq \arg\min_{x} \Phi_i(x; \theta), \quad i = 1, \dots, n,
$$
 (2)

where the reconstruction $\hat{x}_i(\theta)$ is the solution to the lower-level optimization problem, and ℓ is a function that quantifies the quality of the reconstruction, such as the mean squared error $||\hat{x}_i(\theta) - x_i^*||^2$. Examples of learnable parameters θ include feature-extracting filters, wavelet- or shearlet-based systems for regularizers.

Bilevel learning is mathematically appealing as it optimizes the parameters based on target data in an explicit measure of reconstruction quality. However, it poses significant computational challenges. One major difficulty is the fact that evaluating the upper-level cost requires solving the lower-level optimization problem exactly. However, exact solutions to the lower-level problem are typically unattainable in practice, as they are often solved numerically up to a certain tolerance. Achieving very small tolerances is computationally prohibitive, especially for large-scale problems. This necessitates the consideration of inexact solutions with controllable tolerances that are as large as possible to reduce computational cost, yet small enough to maintain the accuracy required for effective optimization.

One common class of methods for solving bilevel problems is gradient-based optimization.

The key ingredient in these methods is the computation of the gradient of the upper level cost with respect to the parameters θ , which is often referred to as the hypergradient. There are several common approaches for the computation of the hypergradient in the literature. The implicit function theorem (IFT) [\[19](#page-13-6)[–23\]](#page-13-7) approach involves differentiating the optimality condition of the lower-level problem, but requires inverting the Hessian matrix of the lower-level objective via iterative algorithms such as conjugate gradient method, which is computationally expensive. Unrolling methods [\[18,](#page-13-5) [24](#page-13-8)[–27\]](#page-14-0), on the other hand compute the hypergradient using automatic differentiation by unrolling the iterations of the optimization algorithm used to solve the lower-level problem. However, this approach can be memory-intensive, especially when a larger number of iterations is used for solving the lowerlevel problem. The piggyback method $|28-30|$ computes the hypergradient by solving an adjoint problem, often in conjunction with the lower-level optimization. In this approach, the lower-level solution and the corresponding adjoint problem are solved simultaneously.

In this paper, we focus on the piggyback method for hypergradient computation, and address several challenges that arise in its practical implementation. First, we propose a framework that allows inexact solutions of the lower-level problem by dynamically adjusting the tolerance during optimization. This helps balancing computational cost and accuracy. Additionally, while piggyback algorithms have been successfully applied, there are no a-posteriori error bounds to control the accuracy of the computed hypergradient. We address this gap by deriving such error bounds, providing a framework for managing inexactness in a principled manner.

Another challenge in applying gradient-based methods to bilevel problems is the choice of stepsize for the upper-level optimization. Convergence analysis for bilevel methods typically assumes highly accurate hypergradients and the use of a fixed, small step-size $[23, 31, 32]$ $[23, 31, 32]$ $[23, 31, 32]$ $[23, 31, 32]$ $[23, 31, 32]$. In the context of piggyback-style computed hypergradients, existing analyses also require highly accurate hypergradients and a sufficiently small, fixed step-size [\[28\]](#page-14-1). However, in practice, determining an appropriate step-size when working with approximate hypergradients is non-trivial. Assuming access to inexact lower-level solutions with controllable error

and inexact hypergradients with a-posteriori error bounds, a condition was developed in [\[33\]](#page-14-5) to adaptively select step-sizes and the required accuracy, ensuring convergence in a robust and cost-efficient manner. To connect and apply the method in [\[33\]](#page-14-5) to primal-dual style differentiation, we propose an a-posteriori error bound analysis for the lower-level and adjoint solutions, as well as a-posteriori error bounds for the inexact hypergradient. We demonstrate the effectiveness of our approach through some bilevel learning tasks, including learning the discretization of the total variation (TV) and training input-convex neural networks (ICNNs) regularizers [\[12,](#page-13-9) [34\]](#page-14-6). The proposed method provides a framework that balances computational efficiency with rigorous error control, making it well-suited for large-scale bilevel learning applications.

1.1 Notation

We denote the Euclidean norm of vectors and the 2-norm of matrices with ∥ ⋅ ∥. The conjugate of a function f is given by $f^*(y) = \sup_x \langle x, y \rangle - f(x)$. The constant μ_f represents the strong convexity constant of a strongly convex function f . The gradient and Hessian of a function f are denoted by ∇f and $\nabla^2 f$, respectively. Additionally, for a function f, the Lipschitz and Hölder continuity constants of the gradient and Hessian are denoted by $L_{\nabla f}$ and $L_{\nabla^2 f}$, respectively.

2 Computation of Hypergradient

2.1 Problem Setting

For the lower-level problem in [\(2\)](#page-1-0), we consider the general optimization problem:

$$
\min_{x \in \mathcal{X}} \{ \Phi(x; K) \coloneqq f(Kx) + g(x) \},\tag{P}
$$

where f and g are proper, convex, lower semicontinuous functions. The corresponding dual problem is given by:

$$
\sup_{y \in \mathcal{Y}} -f^*(y) - g^*(-K^*y), \tag{D}
$$

where f^*, g^* are the convex conjugates of f, g respectively. A standard approach in convex optimization literature [\[35,](#page-14-7) [36\]](#page-14-8) is to formulate this as

a saddle-point problem:

$$
\min_{x \in \mathcal{X}} \max_{y \in \mathcal{Y}} \{ h(x, y, K) \coloneqq \langle Kx, y \rangle + g(x) - f^*(y) \}. \tag{S}
$$

Assuming a solution $(\hat{x}(K), \hat{y}(K))$ of (S) exists, then $\hat{x}(K)$ is also a solution to (P) . The first-order optimality condition can be stated as:

$$
\begin{cases} 0 & \in K\hat{x}(K) - \partial f^*(\hat{y}(K)) \\ 0 & \in K^*\hat{y}(K) + \partial g(\hat{x}(K)). \end{cases} (3)
$$

In this paper, we aim to learn a linear operator K , or specific components of it, in a supervised fashion, via solving the following bilevel problem:

$$
\min_{K} \{ \mathcal{L}(K) = \ell(\hat{x}(K), \hat{y}(K)) \}
$$
 (4a)

$$
(\hat{x}(K), \hat{y}(K)) \coloneqq \arg\min_{x \in \mathcal{X}} \max_{y \in \mathcal{Y}} h(x, y, K). \tag{4b}
$$

The upper-level loss function with respect to the lower-level solution $(\hat{x}(K), \hat{y}(K))$ is represented by ℓ . Throughout the paper, we make the following assumption on ℓ .

Assumption 1. The upper-level loss $\ell : \mathcal{X} \times \mathcal{Y} \rightarrow$ \mathbb{R}_+ is separable, that is, $\ell(x,y) = \ell_1(x) + \ell_2(y)$. Moreover, ℓ_1, ℓ_2 are assumed to be L_1, L_2 -smooth respectively, that is, $\nabla \ell_1, \nabla \ell_2$ are L_1, L_2 Lipschitz. **Remark 1.** We particularly consider $\ell(x, y)$ = $\ell(x)$ for the bilevel learning examples. However, the a-posteriori error bound can be extended to more general ℓ , where we assume $\nabla \ell$ is L Lipschitz.

Since the upper-level problem [\(4a\)](#page-2-1) can be largescale, we are interested in gradient-based bilevel methods [\[15,](#page-13-10) [23\]](#page-13-7) which employ $\nabla \mathcal{L}(K)$ to solve [\(4a\)](#page-2-1). To ensure a well-defined $\nabla \mathcal{L}(K)$ that can be approximated with theoretical guarantees, similar to [\[28\]](#page-14-1), we consider the following regularity assumptions.

Assumption 2. g and f^* are μ_g - and μ_{f^*} -strongly convex, respectively. Moreover, g^* and f are locally $C^{2,1}.^1$ $C^{2,1}.^1$ $C^{2,1}.^1$

Under Assumption [1](#page-2-3) and [2,](#page-2-4) $(\hat{x}(K), \hat{y}(K))$ given K is unique, and the hypergradient can be calculated as follows:

$$
\nabla \mathcal{L}(K) = \hat{y}(K) \otimes \hat{X}(K) + \hat{Y}(K) \otimes \hat{x}(K), \quad (5)
$$

¹For simplicity, we consider locally $C^{2,1}$ functions, but the analysis can be generalized to locally $C^{2,\alpha}$ functions for α ϵ $(0, 1]$, similar to $\overline{28}$

where the adjoint variables $(\hat{X}(K), \hat{Y}(K)) \in \mathcal{X} \times \mathcal{Y}$ solve the quadratic adjoint saddle-point problem below

$$
\min_{X \in \mathcal{X}} \max_{Y \in \mathcal{Y}} \langle KX, Y \rangle + \frac{1}{2} \langle \nabla^2 g(\hat{x}(K))X, X \rangle
$$

-
$$
\frac{1}{2} \langle \nabla^2 f^*(\hat{y}(K))Y, Y \rangle
$$

+ $\langle \nabla \ell_1(\hat{x}(K)), X \rangle + \langle \nabla \ell_2(\hat{y}(K)), Y \rangle,$ (AS)

The following auxiliary lemma will be used in our analysis to provide an a-posteriori control over the optimality gap for strongly convex functions. **Lemma 1.** ([\[37\]](#page-14-9)) Let $\Phi : \mathcal{X} \to \mathbb{R}$ be *µ*-strongly convex and differentiable. Denoting the minimizer of Φ by $x^* \in \mathcal{X}$, for all $x \in \mathcal{X}$ we have

$$
||x^* - x|| \leq \frac{1}{\mu} ||\nabla \Phi(x)||.
$$

Lemma [2](#page-2-4). Let Assumption 2 hold. For a given operator K , and considering the unique saddlepoint (\hat{x}, \hat{y}) of (S) , for all $(x, y) \in \mathcal{X} \times \mathcal{Y}$ we have

$$
||x - \hat{x}|| \le \frac{\|\nabla g(x) + K^* \nabla f(Kx)\|}{\mu_g},
$$
 (6a)

$$
\|y - \hat{y}\| \le \frac{\|\nabla f^*(y) - K\nabla g^*(-K^*y)\|}{\mu_{f^*}}.
$$
 (6b)

Proof. Since \hat{x} is the minimizer of (P) , and from Assumption [2](#page-2-4) the primal problem's objective $f(K \cdot) + g(\cdot)$ is μ_q -strongly convex, utilizing Lemma [1](#page-3-0) one can derive [\(6a\)](#page-2-1). On the other hand, we note that the dual problem (D) is equivalent to :

$$
\min_{y \in \mathcal{Y}} f^*(y) + g^*(-K^*y),\tag{7}
$$

where the objective $f^*(\cdot) + g^*(-K^*)$ is μ_{f^*} -strongly convex. Since \hat{y} is the minimizer of [\(7\)](#page-3-1), utilizing Lemma [1](#page-3-0) again yields the bound [\(6b\)](#page-2-5) as required. \Box

2.2 Piggyback Algorithm

To compute the hypergradient $\nabla \mathcal{L}(K)$, two variations of the piggyback algorithm were introduced in $[29]$. By looking at (5) , computing the hypergradient involves solving two saddle-point problems: [\(S\)](#page-2-0) and [\(AS\)](#page-3-2), respectively. A well-suited algorithm to solve each of these problems is the Primal-Dual hybrid gradient (PDHG) [\[36,](#page-14-8) Algorithm 3]. Since the adjoint problem [\(AS\)](#page-3-2) depends on the

solution of (S) , two different approaches can be taken. One strategy is to solve (S) and (AS) alternatively, where each iterations includes a step of PDHG applied to [\(S\)](#page-2-0), followed by plugging the result in [\(AS\)](#page-3-2) and performing one step of inexact PDHG applied to the adjoint problem, as detailed in [\[38\]](#page-14-11). It was shown in [\[28,](#page-14-1) Theorem 2.2] that under Assumptions [1](#page-2-3) and [2,](#page-2-4) and with a suitable choice of parameters for PDHG, this alternative piggyback algorithm converges linearly to $(\hat{x}(K), \hat{y}(K), X(K), Y(K))$, and thus to the hypergradient $\nabla \mathcal{L}(K)$.

Alternatively, PDHG can be used to solve the saddle-point problem [\(S\)](#page-2-0) first. Since the exact solution $(\hat{x}(K), \hat{y}(K))$ of (S) is not attainable in finite time, an approximate saddle-point $(\tilde{x}(K), \tilde{y}(K))$ is computed instead. With this approximation, we can then solve the saddle-point problem below:

$$
\min_{X \in \mathcal{X}} \max_{Y \in \mathcal{Y}} \langle KX, Y \rangle + \frac{1}{2} \langle \nabla^2 g(\tilde{x}(K))X, X \rangle \n- \frac{1}{2} \langle \nabla^2 f^*(\tilde{y}(K))Y, Y \rangle \n+ \langle \nabla \ell_1(\tilde{x}(K)), X \rangle + \langle \nabla \ell_2(\tilde{y}(K)), Y \rangle, \tag{ASI}
$$

corresponding to the adjoint variables, given an inexact saddle-point of [\(S\)](#page-2-0), using PDHG to find the saddle-point $(X(K), Y(K))$ of [\(ASI\)](#page-3-3). Finally, the approximate hypergradient can be calculated as

$$
z(K) = \tilde{y}(K) \otimes \bar{X}(K) + \bar{Y}(K) \otimes \tilde{x}(K). \quad (8)
$$

This alternative approach is outlined in Algorithm [1.](#page-4-0) The error bound for the resulting approximate hypergradient is given in the following theorem.

Theorem 1. ($\left[28, \text{ Theorem 2.3}\right]$ $\left[28, \text{ Theorem 2.3}\right]$ $\left[28, \text{ Theorem 2.3}\right]$) Under Assump-tion [1](#page-2-3) and [2,](#page-2-4) let $\nu \leq \frac{2\sqrt{\mu_g \mu_{f*}}}{\|K\|}$ $\frac{\partial \mu_g \mu_{f^*}}{\|K\|}, \ \tau = \frac{\nu}{2\mu_g}, \ \sigma = \frac{\nu}{2\mu_{f^*}},$ $\theta \in \left[\frac{1}{1+\nu}, 1\right]$ chosen as in [\[36,](#page-14-8) Algorithm 3]. The iterates of Algorithm [1](#page-4-0) satisfy

$$
\|z(K) - \nabla \mathcal{L}(K)\| \le C \Big(\big(\|\tilde{x}(K) - \hat{x}(K)\| + \|\tilde{y}(K) - \hat{y}(K)\| \big)^{\alpha} + \omega^{\frac{k}{2}} \Big),
$$

for some constant $C > 0$, rate $\omega \leq \theta$ and $\alpha \in (0, 1]$.

Although Theorem [1](#page-3-4) shows the iterates of Algo-rithm [1](#page-4-0) converge to the hypergradient $\nabla \mathcal{L}(K)$, the practical challenges still persist. Running too many

Algorithm 1 Piggyback Algorithm (suggested in [\[28\]](#page-14-1)). Hyperparameter: $\nu \leq \frac{2\sqrt{\mu_g \mu_f *}}{\|K\|}$ $\frac{\mu_g \mu_{f^*}}{\|K\|}$.

- 1: Input: $(x_0, y_0), (X_0, Y_0) \in \mathcal{X} \times \mathcal{Y}$.
- 2: Set $\tau = \frac{\nu}{2\mu_g}$, $\sigma = \frac{\nu}{2\mu_{f^*}}$, and $\theta \in \left[\frac{1}{1+\nu}, 1\right]$.
- 3: Solve [\(S\)](#page-2-0) using PDHG to find $(\tilde{x}(K), \tilde{y}(K))$ as an approximation of $(\hat{x}(K), \hat{y}(K))$.
- 4: Solve [\(ASI\)](#page-3-3) using PDHG to find $(X(K), Y(K))$ as an approximation of $(\overline{X}(K), \overline{Y}(K))$
- 5: Update the hypergradient approximation $z(K) = \tilde{y}(K) \otimes \tilde{X}(K) + \tilde{Y}(K) \otimes \tilde{x}(K)$.

iterations in steps [3](#page-4-1) and [4](#page-4-2) of Algorithm [1](#page-4-0) can lead to an impractically slow performance. Conversely, using too few iterations may cause a loss of convergence in the gradient descent method for the upper-level problem, as it would rely on the approximated hypergradient $\tilde{y}(K) \otimes \tilde{X}(K) + \tilde{Y}(K) \otimes \tilde{x}(K)$ for solving $(4a)$. To tackle this issue, we establish an a-posteriori analysis to quantify the error in the computed hypergradient, allowing us to derive a reliable stopping criterion for steps [3](#page-4-1) and [4](#page-4-2) of Algorithm [1.](#page-4-0)

3 Adaptive Bilevel Learning

3.1 Inexact Piggyback Algorithm and A-Posteriori Error Analysis

Since our focus is on the a-posteriori error bound of the hypergradient evaluated at a given operator K, we simplify the notation in this section by dropping the dependence on K for brevity. Specifically, we denote $\hat{x}(K), \hat{y}(K), \tilde{x}(K), \tilde{y}(K)$ by $\hat{x}, \hat{y}, \tilde{x}, \tilde{y}$. Similarly, we denote $\hat{X}(K), \hat{Y}(K), \overline{X}(K), \overline{Y}(K)$ by $\hat{X}, \hat{Y}, \bar{X}, \bar{Y}$.

Lemma 3. Let Assumption [2](#page-2-4) hold. For a given operator K, and consider the unique saddle-point (\bar{X}, \bar{Y}) of [\(ASI\)](#page-3-3), we have that, for all $(X, Y) \in$ $\mathcal{X} \times \mathcal{Y}$,

$$
||X - \bar{X}|| \leq \delta_1(X, \tilde{x}, \tilde{y})
$$

:=
$$
\frac{||\bar{B}_1X + \nabla \ell_1(\tilde{x}) + K^* \nabla^2 f^*(\tilde{y})^{-1} \nabla \ell_2(\tilde{y})||}{\mu_g},
$$
 (9a)

$$
||Y - \bar{Y}|| \leq \delta_2(Y, \tilde{x}.\tilde{y})
$$

:=
$$
\frac{||\bar{B}_2Y + K \nabla^2 g(\tilde{x})^{-1} \nabla \ell_1(\tilde{x}) - \nabla \ell_2(\tilde{y})||}{\mu_{f^*}},
$$
 (9b)

where $\overline{B}_1 = \nabla^2 g(\tilde{x}) + K^* \nabla^2 f^*(\tilde{y})^{-1} K$, and $\bar{B}_2 = K \nabla^2 g(\tilde{x})^{-1} K^* + \nabla^2 f^*(\tilde{y}).$

Proof. The primal and dual problem correspond to the inexact adjoint saddle-point problem [\(ASI\)](#page-3-3) can be written as:

$$
\min_{X \in \mathcal{X}} \frac{1}{2} \langle \bar{B}_1 X, X \rangle + \langle \nabla \ell_1(\tilde{x}), X \rangle \n+ \langle K^* \nabla^2 f^*(\tilde{y})^{-1} \nabla \ell_2(\tilde{y}), X \rangle \n+ \frac{1}{2} \langle \nabla \ell_2(\tilde{y}), \nabla^2 f^*(\tilde{y})^{-1} \nabla \ell_2(\tilde{y}) \rangle, \quad (10)
$$

$$
\max_{Y \in \mathcal{Y}} -\frac{1}{2} \langle \bar{B}_2 Y, Y \rangle - \langle K \nabla^2 g(\tilde{x})^{-1} \nabla \ell_1(\tilde{x}), Y \rangle + \langle \nabla \ell_2(\tilde{y}), Y \rangle - \frac{1}{2} \langle \nabla \ell_1(\tilde{x}), \nabla^2 g(\tilde{x})^{-1} \nabla \ell_1(\tilde{x}) \rangle.
$$
\n(11)

Using Assumption [1,](#page-2-3) [2](#page-2-4) and Lemma [1](#page-3-0) we derive [\(9a\)](#page-4-3) and [\(9b\)](#page-4-4) as required. \Box

Lemma 4. Let g be μ_q -strongly convex and $L_{\nabla g}$ -smooth, and let g^* be $C^{2,1}$. Then $\nabla^2 g(x)$ is Lipschitz continuous with constant $L_{\nabla^2 g^*}(L_{\nabla g})^3$.

Proof. For x_1, x_2 , let $y_1 = \nabla g(x_1), y_2 = \nabla g(x_2)$, we have:

$$
\|\nabla^2 g(x_1) - \nabla^2 g(x_2)\|
$$

\n= $\|\nabla^2 g(x_1)(\nabla^2 g(x_2)^{-1} - \nabla^2 g(x_1)^{-1})\nabla^2 g(x_2)\|$
\n $\leq \|\nabla^2 g(x_1)\| \cdot \|\nabla^2 g^*(y_2) - \nabla^2 g^*(y_1)\| \cdot \|\nabla^2 g(x_2)\|$
\n $\leq (L_{\nabla g})^2 \|\nabla^2 g^*(y_1) - \nabla^2 g^*(y_2)\|,$

where the last inequality is due to [\[39,](#page-14-12) Theorem 1] and the $L_{\nabla g}$ smoothness of g. Since g^* is $C^{2,1}$ and g is $L_{\nabla g}$ smooth, we have:

$$
\|\nabla^2 g(x_1) - \nabla^2 g(x_2)\|
$$

\n
$$
\leq (L_{\nabla g})^2 \|\nabla^2 g^*(y_1) - \nabla^2 g^*(y_2)\|
$$

\n
$$
\leq L_{\nabla^2 g^*} (L_{\nabla g})^2 \|\nabla g(x_1) - \nabla g(x_2)\|
$$

\n
$$
\leq L_{\nabla^2 g^*} (L_{\nabla g})^3 \|x_1 - x_2\|.
$$

 \Box

Theorem 2. Let Assumption [1](#page-2-3) and [2](#page-2-4) hold. Moreover, let g and f^* be $L_{\nabla g}$ and $L_{\nabla f^*}$ smooth, respectively. For $\epsilon^x, \epsilon^y, \delta^X, \delta^Y > 0$, if $\|\tilde{x} - \hat{x}\| \leq \epsilon^x$, $\|\tilde{y} - \hat{y}\| \le \epsilon^y$. Let $(\tilde{X}, \tilde{Y}) \in \mathcal{X} \times \mathcal{Y}$ such that

$$
\|\tilde{X} - \bar{X}\| \le \delta_1(\tilde{X}, \tilde{x}, \tilde{y}) \le \delta^X \tag{12a}
$$

$$
\|\tilde{Y} - \bar{Y}\| \le \delta_2(\tilde{Y}, \tilde{x}, \tilde{y}) \le \delta^Y, \quad (12b)
$$

then (\tilde{X}, \tilde{Y}) satisfies:

$$
\|\tilde{X} - \hat{X}\| \le C_1^X \epsilon^x + C_2^X \epsilon^y + \delta^X, \tag{13}
$$

$$
\|\tilde{Y} - \hat{Y}\| \le C_1^Y \epsilon^x + C_2^Y \epsilon^y + \delta^Y. \tag{14}
$$

$$
z \coloneqq \tilde{y} \otimes \tilde{X} + \tilde{Y} \otimes \tilde{x}, \tag{15}
$$

we have:

For

$$
\|z - \nabla \mathcal{L}(K)\| \leq (C_1^Y \|\tilde{x}\| + C_1^X \|\tilde{y}\| + \|\tilde{Y}\|)\epsilon^x
$$

+
$$
(C_2^Y \|\tilde{x}\| + C_2^X \|\tilde{y}\| + \|\tilde{X}\|)\epsilon^y + \|\tilde{y}\|\delta^X + \|\tilde{x}\|\delta^Y
$$

+
$$
C_1^Y (\epsilon^x)^2 + C_2^X (\epsilon^y)^2 + \delta^X \epsilon^y + \delta^Y \epsilon^x
$$
(16)

where

$$
C_1^X \coloneqq \frac{L_{\nabla^2 g^*} (L_{\nabla g})^3 \|\tilde{X}\| + L_1}{\mu_g} \tag{17a}
$$

$$
C_2^X :=
$$

\n
$$
\frac{L_{\nabla^2 f} L_{\nabla f^*} ||K|| (||K|| ||\tilde{X}|| + ||\nabla \ell_2(\tilde{y})||)}{\mu_g} + \frac{L_2 ||K||}{\mu_g \mu_{f^*}}
$$
\n(17b)

$$
C_1^Y :=
$$

\n
$$
\frac{L_{\nabla^2 g^*} L_{\nabla g} ||K|| (||K|| ||\tilde{Y}|| + ||\nabla \ell_1(\tilde{x})||)}{\mu_{f^*}} + \frac{L_1 ||K||}{\mu_g \mu_{f^*}}
$$
\n(17c)

$$
C_2^Y \coloneqq \frac{L_{\nabla^2 f}(L_{\nabla f^*})^3 \|\tilde{Y}\| + L_2}{\mu_{f^*}}
$$
(17d)

Proof. Taking similar steps on [\(AS\)](#page-3-2) and defining

$$
\hat{B}_1 = \nabla^2 g(\hat{x}) + K^* \nabla^2 f^*(\hat{y})^{-1} K,
$$

$$
\hat{B}_2 = K \nabla^2 g(\hat{x})^{-1} K^* + \nabla^2 f^*(\hat{y}),
$$

we derive:

$$
\|\tilde{X} - \hat{X}\|
$$

\$\leq \frac{\|\hat{B}_1\tilde{X} + \nabla\ell_1(\hat{x}) + K^*\nabla^2 f^*(\hat{y})^{-1}\nabla\ell_2(\hat{y})\|}{\mu_g}, (18)\$

and

$$
\begin{aligned} \|\tilde{Y} - \hat{Y}\| \\ &\leq \frac{\|\hat{B}_2\tilde{Y} + K\nabla^2 g(\hat{x})^{-1}\nabla\ell_1(\hat{x}) - \nabla\ell_2(\hat{y})\|}{\mu_{f^*}}, \end{aligned} \tag{19}
$$

where (\hat{X}, \hat{Y}) is the saddle-point of [\(AS\)](#page-3-2). Now, from the RHS of [\(18\)](#page-5-0), we can write:

$$
\|\hat{B}_1\tilde{X} + \nabla \ell_1(\hat{x}) + K^* \nabla^2 f^*(\hat{y})^{-1} \nabla \ell_2(\hat{y})\| \n= \|\bar{B}_1\tilde{X} + \nabla \ell_1(\tilde{x}) + K^* \nabla^2 f^*(\tilde{y})^{-1} \nabla \ell_2(\tilde{y}) \n+ (\hat{B}_1 - \bar{B}_1)\tilde{X} + \nabla \ell_1(\hat{x}) - \nabla \ell_1(\tilde{x}) \n+ K^* \nabla^2 f^*(\hat{y})^{-1} \nabla \ell_2(\hat{y}) - K^* \nabla^2 f^*(\tilde{y})^{-1} \nabla \ell_2(\tilde{y})\| \n\leq \|\bar{B}_1\tilde{X} + \nabla \ell_1(\tilde{x}) + K^* \nabla^2 f^*(\tilde{y})^{-1} \nabla \ell_2(\tilde{y})\| \n+ \|\hat{B}_1 - \bar{B}_1\| \|\tilde{X}\| + L_1 \epsilon^x \n+ \|K^* \nabla^2 f^*(\hat{y})^{-1} \nabla \ell_2(\hat{y}) - K^* \nabla^2 f^*(\tilde{y})^{-1} \nabla \ell_2(\tilde{y})\|
$$
\n(20)

where the inequality is due to the L_1 -smoothness of $\ell_1.$ Note that we have:

$$
\|\hat{B}_1 - \bar{B}_1\|
$$
\n
$$
= \|\nabla^2 g(\hat{x}) - \nabla^2 g(\tilde{x})
$$
\n
$$
+ K^*(\nabla^2 f(\nabla f^*(\hat{y})) - \nabla^2 f(\nabla f^*(\tilde{y})))K\|
$$
\n
$$
\leq L_{\nabla^2 g^*}(L_{\nabla g})^3 \|\hat{x} - \tilde{x}\|
$$
\n
$$
+ L_{\nabla^2 f} \|K\|^2 \|\nabla f^*(\hat{y}) - \nabla f^*(\tilde{y})\|
$$
\n
$$
\leq L_{\nabla^2 g^*}(L_{\nabla g})^3 \epsilon^x + L_{\nabla^2 f}L_{\nabla f^*} \|K\|^2 \|\hat{y} - \tilde{y}\|
$$
\n
$$
= L_{\nabla^2 g^*}(L_{\nabla g})^3 \epsilon^x + L_{\nabla^2 f}L_{\nabla f^*} \|K\|^2 \epsilon^y.
$$
\n(21)

We note that:

$$
||K^*\nabla^2 f^*(\hat{y})^{-1}\nabla \ell_2(\hat{y}) - K^*\nabla^2 f^*(\tilde{y})^{-1}\nabla \ell_2(\tilde{y})||
$$

\n= $||K^*\nabla^2 f^*(\hat{y})^{-1}\nabla \ell_2(\hat{y}) - K^*\nabla^2 f^*(\hat{y})^{-1}\nabla \ell_2(\tilde{y})$
\n+ $K^*\nabla^2 f^*(\hat{y})^{-1}\nabla \ell_2(\tilde{y}) - K^*\nabla^2 f^*(\tilde{y})^{-1}\nabla \ell_2(\tilde{y})||$
\n $\leq ||K|| ||\nabla^2 f^*(\hat{y})^{-1}|| ||\nabla \ell_2(\hat{y}) - \nabla \ell_2(\tilde{y})||$
\n+ $||K|| ||\nabla^2 f^*(\hat{y})^{-1} - \nabla^2 f^*(\tilde{y})^{-1}|| ||\nabla \ell_2(\tilde{y})||$ (22)

where the last inequality again utilizes [\[39,](#page-14-12) Theorem 1]. Moreover, we have:

$$
\|\nabla^2 f^*(\hat{y})^{-1} - \nabla^2 f^*(\tilde{y})^{-1}\|
$$

\n
$$
= \|\nabla^2 f(\nabla f^*(\hat{y})) - \nabla^2 f(\nabla f^*(\tilde{y}))\|
$$

\n
$$
\leq L_{\nabla^2 f} \|\nabla f^*(\hat{y}) - \nabla f^*(\tilde{y})\|
$$

\n
$$
\leq L_{\nabla^2 f} L_{\nabla f^*} \|\hat{y} - \tilde{y}\|.
$$
\n(23)

Combining $(20),(21),(22),(23)$ $(20),(21),(22),(23)$ $(20),(21),(22),(23)$ $(20),(21),(22),(23)$ $(20),(21),(22),(23)$ $(20),(21),(22),(23)$ $(20),(21),(22),(23)$, this implies

$$
\|\tilde{X} - \hat{X}\| \le C_1^X \epsilon^x + C_2^X \epsilon^y + \delta^X \tag{24}
$$

where C_1^X , C_2^X are as defined in [\(17a\)](#page-4-3),[\(17b\)](#page-4-4). Similarly, taking the same steps on the RHS of [\(19\)](#page-5-5) yields

$$
\|\tilde{Y} - \hat{Y}\| \le C_1^Y \epsilon^x + C_2^Y \epsilon^y + \delta^Y, \tag{25}
$$

with C_1^Y, C_2^Y as [\(17c\)](#page-5-6),[\(17d\)](#page-5-7). Now, for the hypergradient z, we know

$$
\|z - \nabla \mathcal{L}(K)\| \le \|\tilde{y}\| \|\tilde{X} - \hat{X}\| + \|\tilde{y} - \hat{y}\| \|\hat{X}\| + \|\tilde{x}\| \|\tilde{Y} - \hat{Y}\| + \|\tilde{x} - \hat{x}\| \|\hat{Y}\|.
$$

Adding and subtracting \tilde{X} to \hat{X} in the second term and Y to \overline{Y} in fourth term of the RHS above, applying triangle inequality, employing [\(24\)](#page-6-0) and (25) , we derive the bound (16) as required. \Box

Now, utilizing lemma [1](#page-3-0) and theorem [2,](#page-4-5) we propose an inexact variation of Piggyback algorithm with controllable error on the lower-level iterates as well as the hypergradient, which is outlined in Algorithm [2.](#page-7-0)

3.2 Method of Adaptive Inexact Descent (MAID)

Given the approximate hypergradient provided by Algorithm [2,](#page-7-0) we employ the adaptive backtracking line search scheme introduced in [\[33\]](#page-14-5) to find suitable upper-level step-sizes, and to adaptively adjust the tolerances $\epsilon^x, \epsilon^y, \delta^X, \delta^Y$ required for calculating an approximate hypergradient. The following lemma gives a sufficient decrease condition which we will deploy as the line search rule for upper-level iterations.

Lemma 5. $\left[33, Lemma \right] 3.4$ $\left[33, Lemma \right] 3.4$ $\left[33, Lemma \right] 3.4$ Let assumption [1](#page-2-3) hold, $\lambda \in \mathbb{R}$, and suppose that the upper-level loss ℓ is convex. For each upper-level iteration $t = 0, 1, \ldots$, set $u_t = (\tilde{x}(K_t), \tilde{y}(K_t)), \ \bar{\epsilon} = \max\{\epsilon_t^x, \epsilon_{t+1}^x, \epsilon_t^y, \epsilon_{t+1}^y\},\$ and denoting

$$
\psi(\alpha_k) \coloneqq \ell(u_{t+1}) + \|\nabla \ell(u_{t+1})\| \bar{\epsilon}
$$

+
$$
\frac{L_1 + L_2}{2} \bar{\epsilon}^2 - \ell(u_t) + \|\nabla \ell(u_t)\| \bar{\epsilon} + \lambda \alpha_t \|z_t\|^2.
$$
 (26)

If the line search condition $\psi(\alpha_t) \leq 0$ is satisfied, then the sufficient descent condition $\mathcal{L}(K_{t+1})$ – $\mathcal{L}(K_t) \leq -\lambda \alpha_t ||z_t||^2$ holds.

We denote the *t*-th iterate of the linear learnable parameters by K_t . Considering the bilevel problem [\(4\)](#page-2-7) and utilizing lemma [5,](#page-6-2) the adaptive backtracking line search with restart, outlined in algorithm [3,](#page-7-1) is employed to solve the upper-level problem [\(4a\)](#page-2-1).

4 Numerical Experiments

We now provide numerical experiments to support the theoretical contributions of this work. Section [4.1](#page-6-3) focuses on the problem of learning an improved discretization for the total variation (TV). Using the adaptive algorithm presented in Algorithm [3,](#page-7-1) we demonstrate its potential advantages compared to the native piggyback method without adaptive step-sizes and tolerances, which relies on careful tuning of the learning rate α and accuracy parameters δ and ϵ . Subsequently, we take this a step further to demonstrate the applicability of our algorithm in bilevel settings where the piggyback algorithm is used to learn more expressive regularizers. More precisely, in Section [4.2,](#page-8-0) an ICNN-based regularizer is learned using the proposed algorithm for CT reconstruction, yielding competitive results. The accompanying source code will be made available upon publication.

4.1 Learning the Discretization of Total Variation

In the work of [\[40\]](#page-14-13), the need for a new discretization for the total variation was identified. The aim was to enforce common pixel grid locations of the employed vector fields which in turn promotes rotational invariance that is not granted with the standard discretization. This was later extended to a general (consistent) setting using learnable interpolation filters for the total variation and its second-order extension [\[29,](#page-14-10) [41\]](#page-14-14). This is treated in the setting of standard linear inverse problems, where an image $x \in \mathbb{R}^{M \times N}$ is sought to be reconstructed. As usual, we are given a corrupted observation u and the inverse problem is governed by a μ_q -strongly convex data fidelity term $g(x, u)$ with a linear operator A.

Following [\[29,](#page-14-10) [40\]](#page-14-13), which suggests to take the constraint on the interpolated dual variable Ky

Algorithm 2 Inexact Piggyback Algorithm. Hyperparameter: $\nu \leq \frac{2\sqrt{\mu_g \mu_{f^*}}}{\|K\|}$ $\frac{\mu_g\mu_{f^*}}{\|K\|}$.

1: Input: $(x_0, y_0), (X_0, Y_0) \in \mathcal{X} \times \mathcal{Y}$, accuracies $\epsilon^x, \epsilon^y, \delta^X, \delta^Y \ge 0$

2: function INEXACTPIGGYBACK $(K, \epsilon^x, \epsilon^y, \delta^X, \delta^Y)$

- 3: Set $\tau = \frac{\nu}{2\mu_g}, \sigma = \frac{\nu}{2\mu_{f^*}}, \text{ and } \theta \in \left[\frac{1}{1+\nu}, 1\right].$
- 4: Solve [\(S\)](#page-2-0) to find (\tilde{x}, \tilde{y}) , where $\|\tilde{x} \hat{x}\| \le \epsilon^x$ and $\|\tilde{y} \hat{y}\| \le \epsilon^y$, utilizing [\(6a\)](#page-2-1) and [\(6b\)](#page-2-5)
- 5: Solve [\(ASI\)](#page-3-3) to find (\tilde{X}, \tilde{Y}) , where $\|\tilde{X} \bar{X}\| \leq \delta^X$ and $\|\tilde{Y} \bar{Y}\| \leq \delta^Y$, utilizing [\(13\)](#page-5-9) and [\(14\)](#page-5-10).
- 6: return $z = \tilde{y} \otimes \tilde{X} + \tilde{Y} \otimes \tilde{x}$

Algorithm 3 [\[33,](#page-14-5) Algorithm 3.1] Method of Adaptive Inexact Descent (MAID). Hyperparameters: $\rho, \overline{\rho} \in (0,1)$ control the reduction and increase of the step-size α_k , respectively; $\nu, \overline{\nu} \in (0,1)$ govern the reduction and increase of accuracies δ_k and ϵ_k ; max_{BT} $\epsilon \mathbb{N}$ is the maximum number of backtracking iterations.

instead of the dual variable y . The dual form of total variation can be represented as:

$$
TV(x) = \sup_{y} \langle Dx, y \rangle : ||Ky||_{Z}^{*} \le 1, \qquad (27)
$$

where $\|\cdot\|_Z \coloneqq \|\cdot\|_{2,1,1}$ for $q \in \mathbb{R}^{n \times 2 \times M \times N}$, which is the absolute sum of its n components of the 2-norm of its two components. Using the linear operator K this allows to interpolate the components of $y \in \mathbb{R}^{2 \times M \times N}$, which are located on staggered pixel grids due to the employed finite differences D. Note that Neumann boundary conditions are used here to obtain resulting pixel grids of the same spatial size. Note that the constraint essentially implies that the operator K encompasses a sparse coding for Dx . The corresponding primal problem of (27) is then given by

$$
TV(x) = \min_{q: K^* q = Dx} \|q\|_Z, \tag{28}
$$

Combining [\(28\)](#page-7-4) with a convex data fidelity term $q(x, u)$ in an inverse problem setting, this yields the subsequent saddle-point problem with regularisation parameter $\lambda \in \mathbb{R}^+$:

$$
\min_{x,q} \max_{y} g(x,u) + \lambda \|q\|_Z + \langle Dx - K^*q, y \rangle. \tag{29}
$$

Given the exact solution (\hat{x}, \hat{y}) of (29) , its corresponding adjoint saddle-point problem is then given by

$$
\min_{X,Q} \max_{Y} \langle DX - K^*Q, Y \rangle + \frac{1}{2} \langle \nabla^2 g(\hat{x}, u) X, X \rangle
$$

$$
+ \frac{1}{2} \langle \nabla^2 \lambda \| \hat{q} \|_{Z}, Q \rangle + \langle \nabla \ell(\hat{x}, x^*), X \rangle. \quad (30)
$$

Note that in [\(29\)](#page-7-5), the non-smooth absolute function $\|\cdot\|_{2,1,1}$ does not fully satisfy the regularity assumptions on g. While this would typically require smoothing, we observe that the primal-dual style differentiation approach in bilevel learning

performs robustly even in this less regular setting, similar to the findings in [\[28\]](#page-14-1). Therefore, we directly work with [\(29\)](#page-7-5).

For a given set of corresponding ground truth images and corrupted observations $(x_i^*, u_i)_i$, the standard bilevel setting in [\(4\)](#page-2-7) can be employed, which – given the saddle-point structure of the underlying lower-level problem – can be approached using Algorithm [3.](#page-7-1) The experiments were conducted for the inverse problem of image denoising for a randomly sampled train subset of the BSDS train data set [\[42\]](#page-14-15) with 32 images of size 128×128 . To generate the corrupted observations for the image denoising task, zero-mean additive Gaussian noise ∼ $\mathcal{N}(0, \sigma^2)$ with $\sigma = 25.5$ was used.

The linear operator K was heuristically chosen to consist of $n = 8$ filters with filter kernels 5×5 . The parameters in Algorithm [3](#page-7-1) were set to $\underline{\nu} = 0.5, \ \bar{\nu} = 1.05, \ \underline{\rho} = 0.5, \ \bar{\rho} = \frac{10}{9} \ \text{following} \ [33].$ $\underline{\nu} = 0.5, \ \bar{\nu} = 1.05, \ \underline{\rho} = 0.5, \ \bar{\rho} = \frac{10}{9} \ \text{following} \ [33].$ $\underline{\nu} = 0.5, \ \bar{\nu} = 1.05, \ \underline{\rho} = 0.5, \ \bar{\rho} = \frac{10}{9} \ \text{following} \ [33].$ For comparison between the adaptive and nonadaptive settings, where the latter corresponding to the native inexact version of piggyback, the initial values for ϵ_0 , δ_0 and α_0 were kept the same across both cases. However, in the non-adaptive version, these parameters were fixed throughout the algorithm. Figure [1a](#page-9-0) shows the learned filters with the adaptive Algorithm [3](#page-7-1) and without for $\epsilon_0 = 10^{-3}$, $\delta_0 = 10^{-3}$ and $\alpha_0 = 10^{-2}$, showing that both settings seem to capture very related orientations. While clearly the quantitatively learned filters are very similar, it is of higher interest to investigate the resulting implications on the used computational budget in terms of required lowerlevel iterations. Therefore, Figure [1b](#page-9-0) shows the resulting upper-level loss depending on the required total computational budget in all standard and adjoint primal-dual algorithms for different experimental settings. The benefit of adaptively choosing the step-size can clearly be seen as the resulting upper-level loss decreases smoothly with increasing computational budget in the lower-level solver. On the other hand, the dashed curves show the scenarios with the same starting accuracies and learning rate α as in the adaptive setting, however, these parameters were kept constant during the reconstruction algorithm, where PDHG was adapted for the saddle-point problem in [\(29\)](#page-7-5). Depending on the initial learning rate, the upper-level loss even starts oscillating after an initial phase of decrease.

Qualitative results can be seen in an example in Figure [2,](#page-9-1) which shows reconstructions with standard TV and the learned discretizations with and without using adaptivity. Moreover, for the learned discretization filters, a threshold of $10⁵$ lower-level iterations was used. The visualised results imply that for a limited budget there can even be visible differences in the resulting reconstructions.

Finally, the potential "worst-case" scenario of the oscillating effect is demonstrated, which can arise if the learning rate is too high. In the exemplary setting of $\alpha = 10^{-2}$ and $\epsilon = \delta = 10^{-2}$ in Figure [1b](#page-9-0) (dashed indigo curve), two points during the final learning phase were selected; one at the high-end of the oscillating upper-level loss curve (\triangle) and the other one at the low-end (\star) . Using the learned filters for both settings yielded reconstruction results on the employed test image of 26.44 dB and 26.70 dB, respectively. This showcases that possible discrepancies with regards to reconstruction results depend on the stage of the oscillating upper-level loss. For comparison, the corresponding time-point for the same computational budget as in $($ \blacktriangle) was also retrieved in the adaptive setting $(•)$, which led to a reconstruction result of 26.88 dB for the same test image. Moreover, to support these quantitative differences in the resulting reconstructions, this is supported qualitatively in Figure [3,](#page-10-0) where indeed a comparison even shows minor differences in the reconstructed images, emphasizing the potential benefits of using adaptive backtracking as proposed in Algorithm [3](#page-7-1) for this setting. Note that the non-adaptive setting in Figure [2](#page-9-1) that was obtained for a budget of $10⁵$ lower-level iterations shows quantitative reconstruction results somewhere in-between the two chosen extremes of the oscillating curve.

4.2 Learning Convex Regularizers

In this section, we study the use of our algorithm within a bilevel learning framework to learn more expressive regularizers for imaging tasks. To illustrate this, we consider two convex datadriven regularizers based on input-convex neural networks (ICNNs). The first example is an ICNN which consists of two convolution layers, that is $R_{\theta}(x) = \psi_w(Wz)$ with $z = \psi_w(Vx)$. Here V, W denote learnable convolution layers whose weights constitute the linear operator K, and ψ_w is a

Fig. 1: Learned filters with adaptive and non-adaptive setting (a) and comparison of the upper-level loss depending on the computational budget which is comprised of the total number of upper- and lower-level iterations (b). For one experimental setting, the potential influence of the oscillating behaviour in the non-adaptive case is investigated by examining reconstruction results for different time-points of the oscillating curve (cf. \blacktriangle vs. \star) and the corresponding results using Algorithm [3](#page-7-1) (\blacktriangleright), see also Figure [3.](#page-10-0)

Fig. 2: TV denoising with standard TV and learned discretization filters showing the influence of using the adaptive learning setting at a fixed computational budget of $10⁵$ total lower-level iterations. Best viewed on screen.

smooth activation function defined as:

$$
\psi_w(x) = \begin{cases}\n0 & \text{if } x \le 0, \\
\frac{x^2}{2w}, & \text{if } 0 < x < w,\n\end{cases}
$$
\n(31)

with smoothing parameter $w = 0.01$. Following [\[34\]](#page-14-6), we assume that W is non-negative to ensure the convexity of R_{θ} .

For the image reconstruction experiments, we focus on a sparse-view CT reconstruction task. The training and testing data sets consist of human abdominal CT scans provided by the Mayo Clinic Low-Dose CT Grand Challenge data set [\[43\]](#page-14-16). To simulate measurements, a parallel beam geometry with 200 projection angles is employed, with additional Gaussian noise of standard deviation $\sigma = 2$ added. The training data set consists of 25 randomly sampled images from the original data set, each of size 512×512 .

Following the primal-dual framework introduced in [\[44\]](#page-14-17), we consider the following lower-level problem:

$$
\min_{x,z} \frac{1}{2} \|Ax - u\|^2 + \frac{\mu_g}{2} \|x\|^2 + \delta_C(Vx, z) + \gamma \psi_w(Wz),
$$
\n(32)

where $C = \{(p,q)|\psi_w(p) \leq q\}$, and δ_C denotes the indicator function of C. Here the linear operator A

denotes the X-ray transform with the prescribed geometry of the measurement setting and u is the sinogram, representing the measured projections. For notational convenience, let $f_2(p,q)$ $\delta_C(p,q)$, $f_3(v) = \gamma \psi_w(v)$. We then dualize the data fidelity in [\(32\)](#page-9-2) which gives rise to the saddle-point problem:

$$
\min_{x,z} \max_{y_1,y_2,y_3} \langle Ax, y_1 \rangle + \frac{\mu_g}{2} \|x\|_2^2 - \frac{1}{2} \|y_1 + u\|_2^2
$$

+
$$
\frac{1}{2} \|u\|_2^2 + \langle Vx, y_{2,1} \rangle + \langle z, y_{2,2} \rangle - f_2^*(y_2)
$$

+
$$
\langle Wz, y_3 \rangle - f_3^*(y_3), \quad (33)
$$

where $y_2 = \{y_{2,1}, y_{2,2}\}.$ Additionally, the corresponding adjoint problem can be derived from this formulation, which is necessary for solving the corresponding adjoint saddle-point problem in our primal-dual style differentiation bilevel framework in Algorithm [3.](#page-7-1)

For the second example, we note that by choosing only one layer for the ICNN, we can recover the well-known Fields of Experts (FoE) objective [\[9,](#page-13-11) [45\]](#page-15-0). The regularizer again consists of linear filters and the smoothed activation function ψ_w , which are once more combined with the convex

data fidelity, yielding the following:

$$
\min_{x \in \mathcal{X}} \frac{1}{2} \|Ax - u\|_2^2 + \frac{\mu_g}{2} \|x\|_2^2 + \gamma \psi_w(Kx). \tag{34}
$$

Note that this closely follows the primal objective of the ICNN with two layers in [\(32\)](#page-9-2), but the second variable z that is minimized over can be omitted here due to using only one layer of ICNN. Again, we dualize the non-smooth function as well as the data fidelity, which results in the saddle-point problem

$$
\min_{x} \max_{y_1, y_2} \langle Ax, y_1 \rangle + \frac{\mu_g}{2} ||x||_2^2
$$

$$
- \frac{1}{2} ||y_1 - u||_2^2 + \langle Kx, y_2 \rangle - f^*(y_2). \quad (35)
$$

For the experiments, the FoE regularizer consists of 16 linear filters with filter kernels of size 5×5 (denoted by the linear operator K). Meanwhile, for ICNN the first layer consists of 16 filters of size 5×5 and the second layer of 4×16 filters of size 5×5 . While filtered backprojection (FBP) is the baseline reconstruction method in CT, we also include comparisons with other methods to ensure a comprehensive evaluation. Specifically, we compare the performance of Algorithm [3](#page-7-1) for the previously described 2-layer ICNN in [\(33\)](#page-10-1) trained in a bilevel manner against its adversarially trained counterpart (ACR). Additionally, we include comparisons with the FoE regularizer (i.e., the 1-layer ICNN in (35) , total variation (TV), and the datadriven learned primal-dual method (LPD) [\[46\]](#page-15-1). The specific learning settings are described in the following paragraph.

For the 2-layer ICNN, the parameters in Algo-rithm [3](#page-7-1) are set to $\nu = 0.5, \bar{\nu} = 1.05, \rho = 0.1,$ $\bar{\rho}$ = 1.1. The initial parameters are set to $\alpha_0 = 10^{-4}$, ϵ_0 = 20, δ_0 = 4. The ACR model is trained using the framework described in [\[12\]](#page-13-9). During training, the gradient penalty is set to 10, and the Adam optimizer is employed with a learning rate of $2 \cdot 10^{-5}$. The model is trained for 20 epochs on the data set outlined earlier. For the FoE regularizer, similar as in Section [4.1,](#page-6-3) the parameters in Algorithm [3](#page-7-1) were set to $\underline{\nu} = 0.5$, $\bar{\nu} = 1.05$, $\underline{\rho} = 0.5$, $\bar{\rho} = \frac{10}{9}$. The initial parameters for ϵ_0 , δ_0 and α_0 were each set to 10. For the TV regularizer, we utilize the imple-mentation provided by the Deep Inverse library^{[2](#page-10-3)}.

implementation provided in the publicly available³. reconstructions. They avoid both oversmoothed We perform 500 iterations of proximal gradient descent with a step-size of 10^{-3} and a hand-tuned regularization parameter of 2. For LPD, we use the For our experiments, we employ 2 primal-dual layers and use the AdamW optimizer [\[47\]](#page-15-2) implemented in PyTorch [\[48\]](#page-15-3), with a learning rate of 10−³ . Training is conducted for 30 epochs on the previously described data set.

> Figure [4](#page-11-1) shows the qualitative results of reconstructing the test image in the sparse-view measurement scenario for all the above described methods as well as the corresponding ground truth image. Visually, the reconstruction results of the 2-layer

ICNN trained using our proposed bilevel learning approach, as well as those from the learned primal-dual (LPD) method, exhibit high-quality reconstructions. They avoid both oversmoothed artifacts and overly fine-grained structures, which can often occur with other reconstruction methods. To support these results, we also show quantitative results in Table [1,](#page-12-5) which contains peak signal-tonoise ratio (PSNR) and structural similarity index measure (SSIM) for all methods on the employed test phantom. Note that this underlines the qualitative impressions from Figure [4.](#page-11-1) While the best scores are obtained using LPD, also the ICNN regularizer trained in our bilevel settings shows very competitive results. To some extent this can also be explained the number of learnable parameters which is in a ten-fold increase for LPD. On the

 3 [https://deepinv.github.io/deepinv/auto_examples/](https://deepinv.github.io/deepinv/auto_examples/unfolded/demo_learned_primal_dual.html) [unfolded/demo_learned_primal_dual.html](https://deepinv.github.io/deepinv/auto_examples/unfolded/demo_learned_primal_dual.html)

other hand, the Fields of Experts regularizer that was trained using Algorithm [3](#page-7-1) shows remarkable reconstruction results given its reduced complexity and limited number of learnable parameters. Even more interestingly, using the exact same architecture for the 2-layer ICNNs, our bilevel learning framework manages to outperform ACR by a large margin. Since they have identical learnable parameters, this shows very well the efficiency of the employed bilevel learning framework using primaldual style differentiation. Overall the experiments show competitive results of FoE and ICNN-based regularizers trained using Algorithm [3.](#page-7-1) Similar results can also be expected in more challenging scenarios such as limited angle measurement settings, and the entire framework can be extended directly to other linear inverse problems with data-driven and potentially non-smooth regularizers.

Table 1: PSNR and SSIM values of test reconstructions shown in Figure [4](#page-11-1) for different methods for sparse-view CT reconstruction. Best score for each metric in bold, second-best underlined.

Method	PSNR ↑	SSIM ¹	$#$ Parameters
FBP	21.07	0.23	
TV	28.68	0.74	
FoE [9]	30.69	0.86	400
ICNN (ACR) [12]	29.32	0.79	2000
ICNN (Bilevel)	31.43	0.86	2000
LPD [46]	34.18	0.88	50397

5 Conclusions

In this work, we proposed a-posteriori error bounds for hypergradients computed via primal-dual style differentiation. By integrating this error analysis and control into an adaptive inexact method, we developed a robust and cost-efficient training framework leveraging primal-dual style differentiation. Specifically, we introduced a bilevel learning framework for training regularizers in variational image reconstruction, utilizing primal-dual style differentiation. In the scenario of learning improved discretizations of the total variation, we compared our adaptive learning framework to the non-adaptive case, highlighting its superior performance, especially with a constrained computational budget and its robust reconstruction results. Additionally,

by reformulating well-known data-adaptive convex regularizers, we demonstrated the effectiveness of inexact primal-dual style differentiation in training these regularizers, achieving superior performance compared to state-of-the-art methods.

For future work, extending our analysis to nonsmooth variational problems would be a valuable direction. Furthermore, adapting this framework to stochastic settings could offer significant speed-ups and enable application to larger data sets. Finally, exploring the connections between this framework and other inexact methods, such as implicit function theorem-based approaches with linear solvers and automatic differentiation, represents another promising avenue for research.
