## Abstract

The NLLG (Natural Language Learning & Generation) arXiv reports assist in navigating the rapidly evolving landscape of NLP and AI research across cs.CL, cs.CV, cs.AI, and cs.LG categories. This fourth installment captures a transformative period in AI history—from January 1, 2023, following ChatGPT’s debut, through September 30, 2024. Our analysis reveals substantial new developments in the field—with 45% of the top 40 most-cited papers being new entries since our last report eight months ago—and offers insights into emerging trends and major breakthroughs, such as novel multimodal architectures, including diffusion and state space models. Natural Language Processing (NLP; cs.CL) remains the dominant main category in the list of our top-40 papers but its dominance is on the decline in favor of Computer vision (cs.CV) and general machine learning (cs.LG). This report also presents novel findings on the integration of generative AI in academic writing, documenting its increasing adoption since 2022 while revealing an intriguing pattern: top-cited papers show notably fewer markers of AI-generated content compared to random samples. Furthermore, we track the evolution of AI-associated language, identifying declining trends in previously common indicators such as “delve”.

## 1 Introduction

Keeping up with the rapid advancements in Artificial Intelligence (AI) is becoming increasingly challenging for both researchers and professionals. Today, more scientific preprints are published than ever before, accelerating the pace of progress. In this environment, researchers and professionals who wish to stay informed about the latest developments often cannot wait for publications in journals and conference proceedings, as the information can quickly become outdated.

The NLLG Quarterly arXiv reports [11, 36, 6] produced by the Natural Language Learning & Generation (NLLG; <https://nllg.github.io/>) Lab take a different approach by exploring and presenting cutting-edge papers based on their immediate impact in the scientific community—specifically, through the analysis of time-normalized citation counts. This current report is the

---

\*<https://nllg.github.io/>

fourth in the series and continues to offer a comprehensive examination of the most influential AI papers published on arXiv, this time between January 1, 2023, and September 30, 2024.

By analyzing the top-cited papers, our goal is to highlight key trends and breakthroughs shaping the future of AI. We focus on arXiv due to its critical role as a preprint server for disseminating cutting-edge research, particularly within the computer science community [10, 7].

Besides presenting the list of top-cited papers in the given time frame, each report has a particular focus of analysis, contrasting top papers with random arXiv papers. While our previous reports focused on (1) the geographic and institution-related affiliation of top papers, finding that Europe and academia are underrepresented compared to random papers, and (2) the writing quality of top papers, finding that they are better written according to various criteria than random papers, the current report focuses on AI generated content in top papers vs. random papers. This is an important research question as LLM generated content may correlate with writing quality which in turn might affect citation counts, perhaps explaining in part the high ranks of some papers.

The key insights from this report are: (i) AI research continues to focus on large language models (LLMs) but is increasingly exploring alternatives to the transformer architecture, including diffusion and state space models [37, 38]; (ii) while the field of Natural Language Processing (NLP; cs.CL) continues to dominate the top papers, its importance, in terms of papers within the top-40, has successively decreased over the course of our previous reports. Computer vision (cs.CV) and more general machine learning (cs.LG) are more strongly represented, in turn; this may indicate a shift towards broader and more diversified (multimodal) architectures. (iii) While the use of LLMs to assist in writing is on the rise overall, our analysis of the top-40 papers reveals that their use remains surprisingly low in this subset, suggesting a potential inverse correlation between the use of LLMs and the overall quality of research conducted. We also show that certain keywords that were previously indicative of LLM usage, such as *delve*, are already decreasing in frequency again, perhaps suggesting that newer LLMs have other vocabulary preferences. We make the code and data artifacts produced for the analysis in this work publicly available at <https://github.com/NL2G/Quarterly-Arxiv>.

## 2 Methods

As in our previous arXiv reports [11, 36, 6], we use week-based normalized z-scores of citation counts to identify the most influential papers for the categories AI, CV, CL and LG. Here, we briefly summarize the setup:

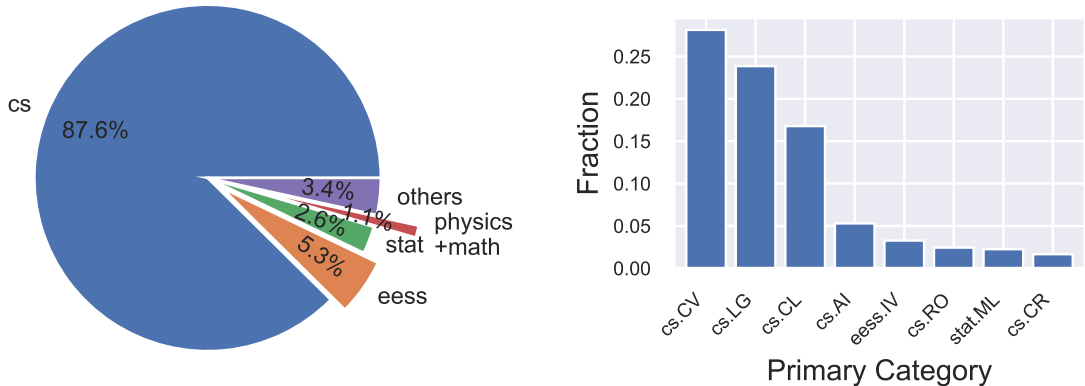

1. **Data Retrieval:** We use an arXiv Python API<sup>1</sup> to download metadata of all papers belonging to any of the arXiv categories cs.CL, cs.AI, cs.CV and cs.LG that were published from 2023/01/01 to 2024/09/30. The citation counts are dependent on the retrieval date: **2024/11/20**. We refer to this new dataset as `arxiv-09/24`.
2. **Paper Ranking:** As in our previous reports, we use a SemanticScholar Python API<sup>2</sup> to determine the citation counts of each paper in `arxiv-09/24`. Next, for each paper’s citation count, we calculate the normalized z-score compared to all papers that were published in the same week:<sup>3</sup>

---

<sup>1</sup><https://github.com/lukasschwab/arxiv.py>

<sup>2</sup><https://github.com/danielnsilva/semanticsscholar>

<sup>3</sup>We average these z-scores across each possible week start; Monday, Tuesday, etc..

(a) Top-level category distribution. The categories math and physics are merged together. (b) Top 8 sub-category distribution in our dataset.

Figure 1: Distribution of top-level and sub-categories

$$z_{i(t)} = \frac{c_{i(t)} - \text{mean}(\mathbf{c}(t))}{\text{std}(\mathbf{c}(t))} \quad (1)$$

$$\hat{z}_{i(t)} = \text{mean}(\mathbf{z}_{i(t^d)}) - \text{std}(\mathbf{z}_{i(t^d)}) \quad (2)$$

for paper  $i$  published in week  $t$  with citation count  $c_{i(t)}$ ;  $\mathbf{c}(t)$  is the list of citation counts of all papers published in week  $t$ . For more details see [36]. Sorting by these z-scores allows us to fairly select the top 40 papers throughout a time period.

- Manual Evaluation:** We manually confirm the top-40 papers and remove those that were published before their arXiv release. As these papers already gathered citations outside of arXiv, leaving them in would introduce bias. We determine these prior releases based on web searches. We refer to the dataset of top-40 papers as `arxiv-09/24-top40`.

### 3 Data Exploration

In this section, we explore our dataset to highlight the overall trends in numbers and citation counts since 2023/1/1, notably discussing the months from 2024/01/31 (our last report) to 2024/09/30.

**Data Distribution** Table 1 shows how this report’s data sets compare to the previous reports. Compared to the previous report, the number of papers almost doubled. This is expected as this report covers a larger time span than each of the previous ones. ArXiv categories are composed of a top-level category, e.g. cs for computer science and a sub-category, e.g. CL for natural language processing (computation & language).<sup>4</sup> Figure 1a shows the distribution of top-level categories in

<sup>4</sup>See [https://arxiv.org/category\\_taxonomy](https://arxiv.org/category_taxonomy).

Dataset name	Size	Time period	Categories	Search Query
arxiv-09/24	127,127	2023/01/01–2024/09/30	139	cs.CL, cs.LG, cs.AI, cs.CV
arxiv-09/24-top40	40		6	
arxiv-01/24	71,139	2023/01/01–2024/01/31	135	cs.CL, cs.LG, cs.AI, cs.CV
arxiv-01/24-top40	40		6	
arxiv-09/23	47,331	2023/01/01–2023/09/30	130	cs.CL, cs.LG, cs.AI, cs.CV
arxiv-09/23-top40	40		6	
arxiv-06/23	20,843	2023/01/01–2023/06/30	123	cs.CL, cs.LG
arxiv-06/23-top40	40		5	

Table 1: This table gives an overview of the datasets that we create in this and our previous reports. The column *Size* indicates the number of data samples. The column *time period* shows the time frame covered in the dataset. *Categories* shows the number of unique primary categories and *search query* shows, which arXiv categories were included in the API search request.

(a) Absolute publication counts per primary category per month.. (b) Relative publication counts per primary category per month.

Figure 2: Absolute and relative citation counts.

our data set. Compared to our last report, there are no big changes. The most notable differences are *physics+math* dropping from 2.2% to 1.1%, *cs* gaining 0.6% and *others* gaining 0.7%. Further, Figure 1b shows the distribution of the 8 most common sub-categories. Here, the most notable difference to the previous report is *cs.RO* (Robotics) overtaking *stat.ML*. Overall, Computer Vision (cs.CV) and Machine Learning (cs.LG) dominate with above 20% of all papers, Natural Language Processing (cs.CL) is third.

**Publication counts over time** Next, we analyze the publication counts per month per search Arxiv category.<sup>5</sup> Figure 2a shows the absolute number of publications per month per primary category. We can see that the numbers are slowly increasing over the months. Like in the previous reports, the most frequent category is cs.CV, followed by cs.LG and cs.CL. Also, each category has a wave-like pattern with high-publication months followed by low-publication months. Our

<sup>5</sup>As compared to the previous reports with week-wise plots, we choose a month-wise plot to be less prone to outliers and because this new report covers a larger time span.

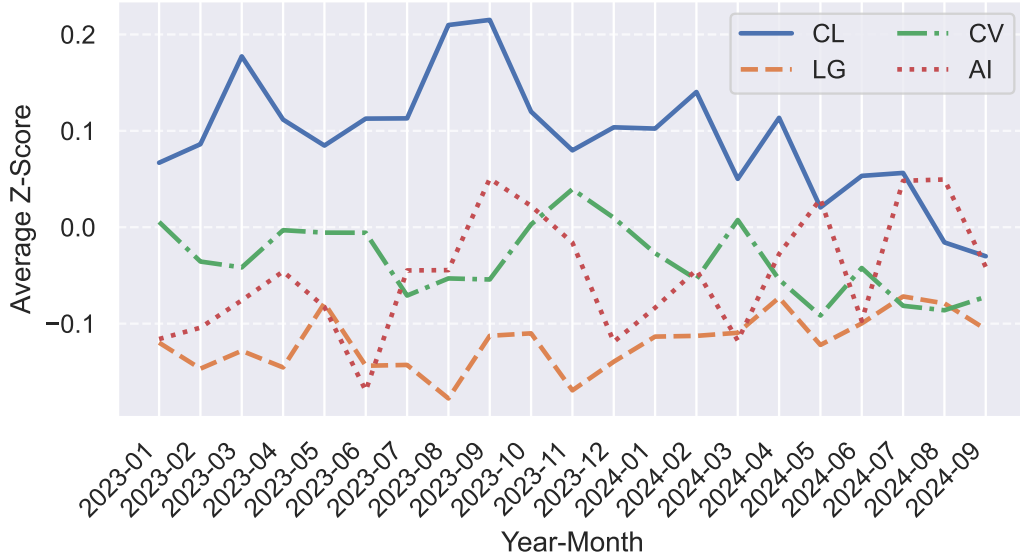

Figure 3: Average z-score per month.

previous reports speculate that this is caused by conference schedules. To further visualize these patterns, Figure 2b shows the relative publication counts per month, i.e., each absolute number is divided by the month’s total. Interestingly, it seems that cs.CV is inverted to cs.CL and cs.LG. That means, cs.CV publications are higher when cs.CL and cs.LG publications are lower and vice versa; and all of them follow a cyclic pattern. A third interpretation would be that the research progress is slowing down, but given the high number of new top40 papers (see Section 4) this seems unlikely. Future work may further investigate this.

**Z-Scores over time** With respect to citation counts, we analyze the average z-score per month (see Figure 3). For each month the cs.CL papers are the most influential, except August 2024, where cs.AI has the highest scores. Also, the plots seem to converge over the recent months, towards a z-score of -0.05. This might unveil a small bias that is introduced by highly influential older papers receiving more citations faster than less cited papers published in the same week or highly influential newer papers. Another cause might be the higher volume of papers in the more recent months.

## 4 Top-40 papers

Tables 2 and 3 show the top 20 and top 21-40 papers of the time period from 2023/1/1 to 2024/9/30. Since our last report, 11 newly published papers were included into our list, including all of the top 3 papers.<sup>6</sup> Additionally, 7 papers that were released before 2024/1/30 but not listed in our

<sup>6</sup>This time, we also noticed a bug in SemanticScholar attributing over 900 citations to the paper [5], which would make it the most influential paper on our list. However, most citations are actually listed as references in the citing paper, but merely published in the same journal. For this reason, we exclude this paper from our list.

previous report are now included. Therefore, 45% of the top 40 papers have changed compared to our last report. Most of the newly included papers introduce new foundation models, e.g. Qwen2 [34], a family of multi-lingual open-source LLMs by Alibaba; LLaMA 3 [16] a family of open source LLMs by Meta; Phi3 [1], a family of small open-source LLMs by Microsoft; Gemini 1.5 [29] a family of closed-source LLMs by Google; DeepSeek-V2 [8], a Mixture-of-Experts LLM by Deepseek-AI; and ChatGLM [15], a family of Chinese and English trained open-source LLMs by Zhipu-AI. Additionally, some works consider new architectural and training paradigms. For example, Transfusion [37] combines diffusion with next-token prediction to train multi-modal transformer models. Kolmogorov-Arnold Networks [26] offer an alternative to multi-layer perceptrons; and Vision Mamba [38] leverages the recently proposed Mamba architecture [18] in a computer vision setting.

Of the recurring papers on our list, the highest position gains are achieved by Direct Preference Optimization (DPO) [28], a training method for human alignment (+7 ranks) and 3D Gaussian Splatting, a method enabling real time novel-view synthesis by inferring volumetric representations of a scene (radiance fields) (+19 ranks)[20]. Also, on rank 10, a survey about retrieval augmented generation (RAG) [12] enters our list. It has already been published in December 2023, which could indicate that more researchers are now working on this topic. Most ranks are lost by PaLM-E (-17) [9] and Baichuan 2 (-14) [33], which is likely caused by the introduction of newer, more competitive LLMs. Also, *Visual Instruction Tuning* [24] has lost 11 ranks, likely because the follow-up paper *Improved Baselines with Visual Instruction Tuning* [25] was introduced, which has now entered our list at rank 17. Further, the prompting technique Tree of Thoughts [35] has lost another 13 ranks, perhaps because of a costly usage and difficult setup in practical applications. It may also highlight a decrease of interest in prompting techniques. Generally, among the primary categories of the top papers are distributed into 1 cs.GR, 1 cs.SE, 2 cs.AI, 8 cs.LG, 11 cs.CV and 17 cs.CL papers (see Figure 4). While there is no cs.CV paper amongst the top 10 anymore, their number increased by 2, which might show a slight focus shift towards computer vision. Interestingly, while still dominating, cs.CL seems to be on the decline in favor of cs.CV and cs.LG; this indicates that more diversified foundation models across different AI subfields become a focus. Figure 4 also shows that there is a relatively strong increase in new papers in the top-20 and top-40 lists since our earlier reports; this may partly be explained by the relatively large time gap of 8 months since our last report.

Table 3: **Top 21-40** papers with their titles, primary categories (cs.XX), links, publication weeks, citation counts, z-scores, and trends in rankings compared to the top-40 lists in our previous report [36], ranked by z-scores as of January 21, 2024. Row colors correspond to the publication time: white (2023/1/1-2023/6/30, added in arxiv-06/23), light gray (2023/7/1-2023/9/30, added in arxiv-09/23), and gray (2023/10/1-2024/1/31, added in arxiv-01/24), and lime (2024/1/31-2024/9/30, added in arxiv-09/24, i.e., this report).

(a) Inclusion of the current top 20 resp. top 40 papers in the previous reports' top 20 resp. top 40 papers. (b) Distribution of arXiv categories among the current and previous reports' top 20 and top 40 papers.

Figure 4: Comparison of the current and previous top papers.

## 5 AI generated content in scientific papers

The advance of LLMs has made it simple to generate and paraphrase new texts. Hence, researchers also use LLMs in the process of writing scientific papers [23]. As this report's focus topic, we extend previous findings with a specific focus on (i) AI related sub-fields of arXiv and on (ii) top-40 papers.

### 5.1 Related work

Many works consider the detection of AI generated texts [31]. Here, we give a brief overview of related work regarding the detection regarding scientific publications. Liang et al. [23] analyze papers from multiple online repositories, including arXiv and determine that the use of generated content indeed increased a few weeks after the release of ChatGPT. They use a corpus-level detection method [22] that estimates the fraction  $\alpha$  of AI generated text. To do so, they (1) construct fully human-written and AI-generated data sets, and (2) use maximum likelihood estimation to learn an estimator that predicts  $\alpha$  for mixed distributions (from 1). For *cs* papers on arXiv, they estimate that a fraction of over 17.5% of all introduction sections and abstracts (combined into a single corpus) was generated in February 2024. Additionally, they find that the words *realm*, *intricate*, *showcasing*, *pivotal* are the most disproportionately used words by LLMs and displaying their frequency also highlights the increased use of generated content. Contemporaneously with them, Geng and Trotta [13] also propose a word frequency based method. They use arXiv abstracts published before the release of ChatGPT and rewrite them with the LLM to determine ground truth frequency changes. Then, they test different models to predict LLM impact and show their performance on unseen data. Interestingly, besides common LLM generated words, they also find that some words, like *is* and *are* are decreasing in frequency. Gray [17] specially focuses on the increasing use of specific words or word groups without learning an estimator. For example, the number of papers that use two words from “*intricate*, *meticulous*, *meticulously*, *commendable*” strongly increases. Another work specifically focusing on changes in word usage is Kobak et al.

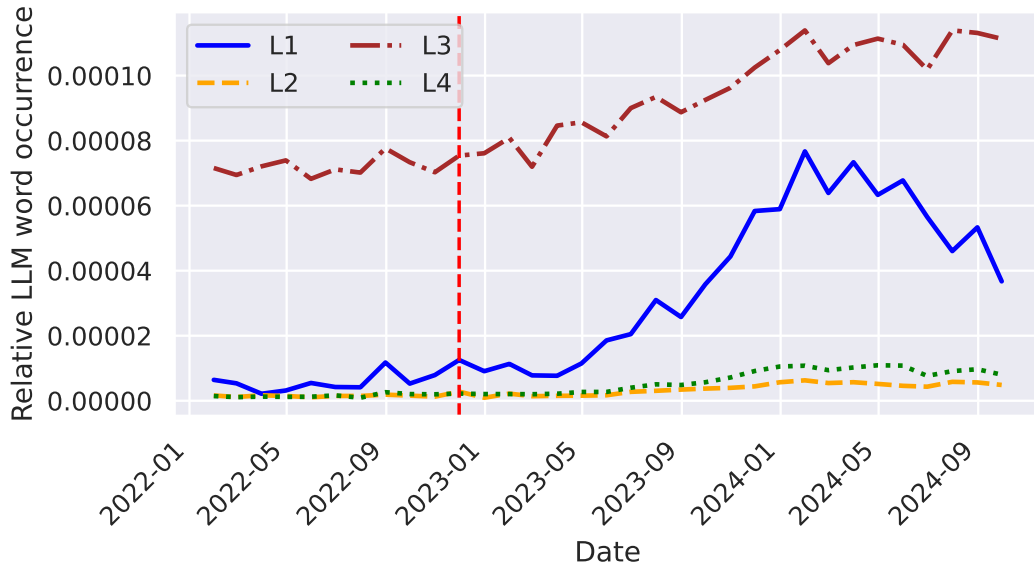

Figure 5: Relative word frequency per “LLM-word” list per month normalized by list length. List 1: [23], List 2: <https://github.com/FareedKhan-dev/Detect-AI-text-Easily>, List 3: [21], List 4: [3].

[21]. They explore the changes of word frequencies in PubMed abstracts since 2010 and show that the effects of the introduction of LLMs even outweighs terms like *pandemic* during Covid-19. As a result, they identify 319 style words with elevated usage since the release of ChatGPT.

A different line of work uses learned black-box LLM detection tools to quantify the usage of LLMs in academic writing. Akram [2] uses an online AI detection tool to show increased use of LLM generated content in computer science papers on arXiv and Picazo-Sanchez and Ortiz-Martin [27] explore different detectors for abstracts of multiple sources, but not in a diachronic comparison.

By now, some subject specific works also explore specific domains based on word-frequencies, like dental research [30] and astronomy [3]. Newer work shows that AI generated content is also used in scientific presentations and thereby also becomes a part of the human spoken language [14]. This is also explored by [32] who analyze 20,000 Youtube channels and find increasing use of LLM terminology.

Our work differs from these works by our specific focus on four selected subfields of the arXiv computer science category. Notably, we assess whether the amount of AI generated content varies between the most influential papers and randomly chosen ones. This is an intriguing question as (1) on one hand AI usage may have improved the writing quality and have supported the high citation counts, but (2) on the other hand the authors of top papers may have the most resources to optimize human written texts and (3) not using AI may (perhaps) lead to a more distinctive writing style, increasing the chance of the paper to be remembered and cited. Also, while most of the works only consider the abstract and introduction, we consider a larger part of the papers. Additionally, we explore how the usage of “LLM words” from different sources impacts the evaluation.

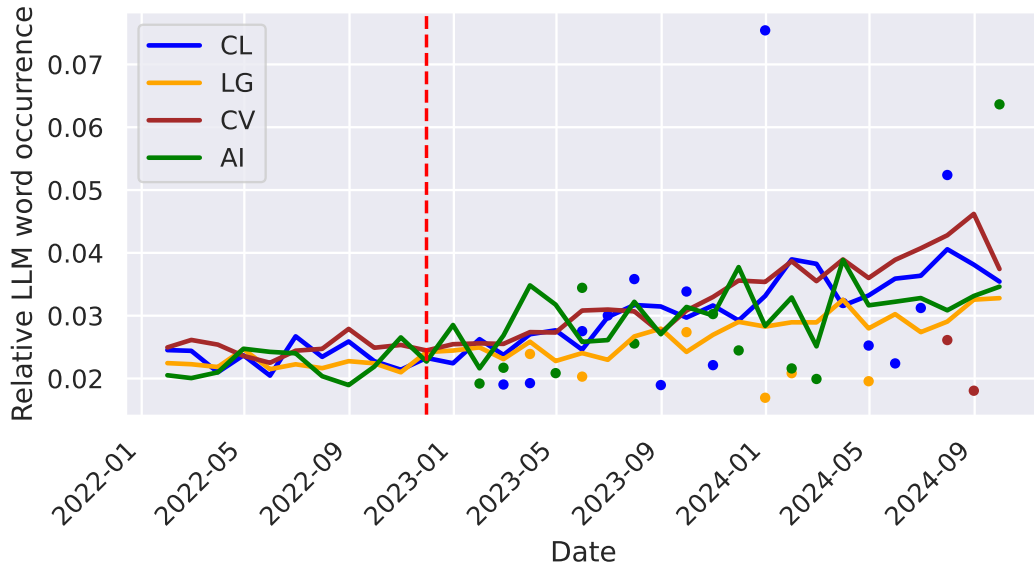

Figure 6: Relative word frequency per “LLM-word” per month and arXiv category. Frequencies per paper are aggregated by median. The points indicate the frequency of words for top-40 papers released in the respective months.

## 5.2 Methodology

Approaches of previous work can be grouped into three categories [21]: (1) detectors leveraging LLMs, (2) estimating mixture models and (3) zero-shot frequency based. Due to ease of setup, we apply two detectors leveraging LLMs: FastDetectGPT [4], a method that compares the input text to sampled model outputs and Binoculars [19], a method that uses two closely related LLMs to determine whether the output of a model is more expected by a second model (cross-perplexity) than the human-written content. Additionally, we consider several word-lists for zero-shot frequency based detection: (1) the four top words by [23], (2) a list compiled by user Fareed Khan on github<sup>7</sup>, (3) the style words discovered by [21] and (4) the 100 words identified by [3]. These are lists of words that people identified to be used more frequently by LLMs than by humans.

To compare the top-40 papers to general papers on arXiv, we collect the PDF files of 10 random papers for each weekday from 2022/01/01 to 2024/09/30. Next, we use marker<sup>8</sup> to extract the text content of these papers and the top-40 papers into markdown. This amounts to a total of 7144 papers (for 6 days only 9 papers were fetched). We use a larger time-span than the arXiv reports to be able to visualize changes since the release of ChatGPT (11/30/2022). The extracted data can be noisy and there is no clear way to extract only relevant content. As a simple heuristic, we

<sup>7</sup><https://github.com/FareedKhan-dev/Detect-AI-text-Easily>

<sup>8</sup><https://github.com/VikParuchuri/marker>

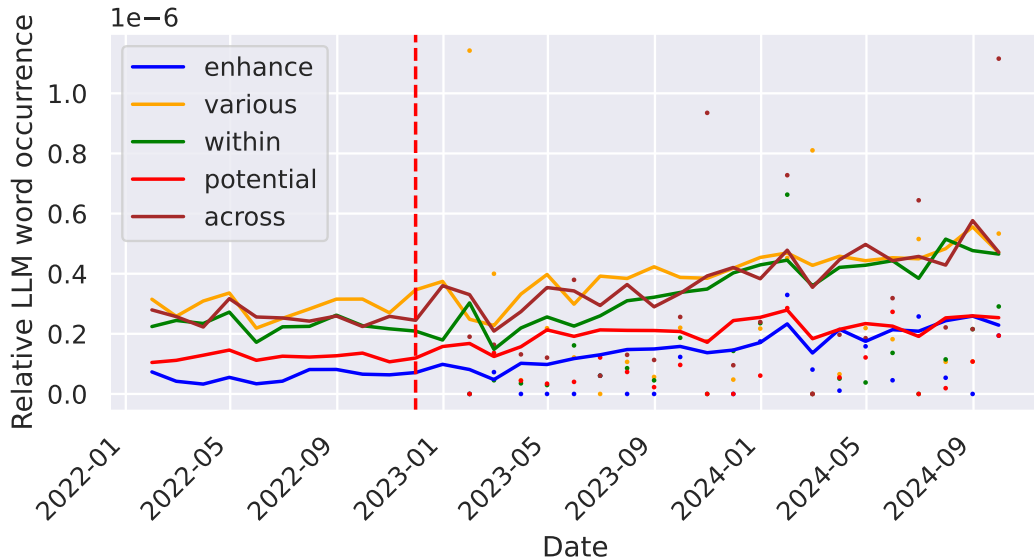

Figure 7: Top 5 words with the highest frequency change over time for random papers (line plot) and top-40 papers (scatter plot). For the selection, we average the relative frequencies of all papers in each month. Then, we take the median of the 11 months in 2022 till ChatGPTs release and of the 9 first months of 2024 and choose the words that show the highest increases.

use the first 40% of each paper for the experiments. This should cut off the references and in many cases also most tables that are usually presented in the results sections.

**Choosing the word lists** To choose the most reasonable lists of “LLM words”, for each list we determine the relative word frequency per month as follows:

1. Let  $C_{i,j}$  represent the count of the  $j$ -th “LLM-word” in the  $i$ -th paper of the month.
2. Compute the total “LLM-word” count for all papers and words of the month:

$$C_{\text{total}} = \sum_{i,j} C_{i,j}$$

3. Determine the normalized relative word frequency:

$$f_{\text{avg}} = \frac{C_{\text{total}}}{T \cdot N}$$

where  $T$  is the total word count of all papers for the month and  $N$  is the number of “LLM-words” in the list.

We plot the resulting frequencies over time in Figure 5. While all four word lists show a frequency increase over time, it is stronger for the words in List 1 and List 3. Notably, the word frequency in List 3 is already quite high before the release of ChatGPT, which shows that their words are more common in general, but still have increased since the release of ChatGPT. Another interesting finding is that List 1, which is composed of only 4 words is decreasing in frequency since early 2024. Perhaps this correlates with the release of newer models, prominently GPT4o in May 2024, that might use different training data. For the next experiments, we only use List 1 and List 3, due to their pronounced frequency change. Note, as a limitation, that we do not test for causality and some increases in word usage may be attributed to other factors like general language change and changes in the scientific fields due to the new technology. Causality may be given for some of the lists based on the methods their authors used.

### 5.3 Results

**Word-frequencies** Next, for each paper in our dataset of 7144 papers, we determine the word-frequencies for List 1 and 3, sum them over all words and divide by the total word count of that paper. For each arXiv category, we select the median over all papers per month as a robust measure. Then, we plot the resulting relative frequency of LLM words over time. For each paper  $k$  in our dataset of  $n = 7144$  papers, we compute the relative frequency of “LLM-words” as

$$f_k = \frac{\sum_j C_{k,j}}{T_k}$$

where  $C_{k,j}$  is the count of the  $j$ -th word in List 1 or List 3 for paper  $k$ , and  $T_k$  is the total word count of paper  $k$ . For each arXiv category and month, we determine the median relative frequency as  $f_{\text{median}} = \text{median}(\{f_k\})$  for all  $k$  in the given category and month. Finally, we plot  $f_{\text{median}}$ , the resulting median relative frequency of “LLM-words” over time. For the top-40 papers that we determined in Section 4, we do the same and add the results as scatterplots (see Figure 6). That means, each point indicates the amount of AI generated content (based on word frequencies) in the current top-40 papers that were released in the respective month.

First, looking at the line-plots we can indeed see a steady increase of LLM word frequencies over time, confirming the previous findings that LLM-usage for academic writing is increasing. In our dataset, cs.CV has the highest frequencies for most months but this was also the case before the release of ChatGPT. cs.LG has the lowest frequencies. For the top-40 papers, most of them (22 out of 29 month+category combinations, i.e. the points in the graph) are below the median frequencies of the random papers, which indicates that these papers may use less AI generated content than others. However, especially the cs.CL category shows a wider variance, where some months lie above the median frequency.

Further, Figure 7 shows the development of the top 5 words with the highest frequency change (of the selected word lists) from January 2022 to September 2024 for the random papers vs. the top-40 papers. All words are relatively common, so seeing their increase is surprising. Also, rather than a jump in usage, their frequencies are increasing steadily. Again, the top-40 papers rarely show higher frequencies than the random ones. For some months, the words “within” and “across” have high frequencies among the top-40 papers, as well. In comparison previous key words used to determine LLM usage, like “delve” (see Figure 8) are declining in usage, i.e. contemporary LLMs seem to have been adapted.

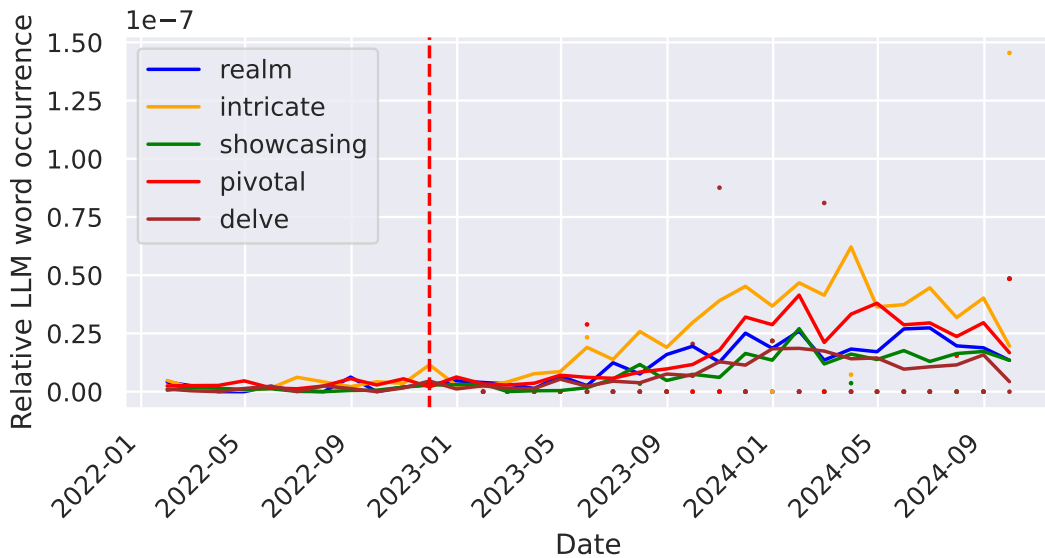

Figure 8: Previous top 4 words [23] & “delve” for random papers (line plot) and top-40 papers (scatter plot).

**Detection Tools** When we use FastDetectGPT and Binoculars, we can also identify very slight upward trends in the amount of generated content. For example, Figure 9 shows the absolute number of papers flagged as generated by Binoculars.<sup>9</sup> While there is a clear increase from 0.1% to 0.8% this type of detection seems to be too strict for our use-case as it assumes fully LLM-generated content. Plotting the detector scores as a line plot does not give conclusive results. Also (unsurprisingly), among the top-40 papers none was flagged as fully AI generated.

<sup>9</sup>They propose two thresholds above which a text is generated. We use the lower one.

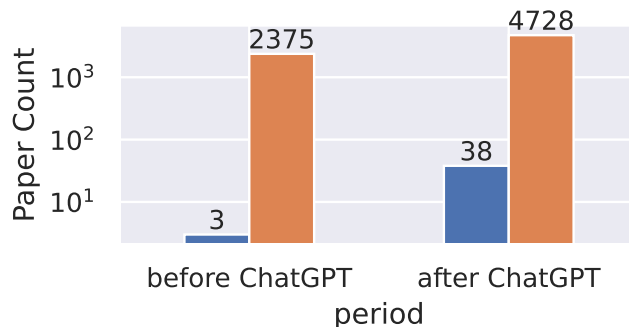

Figure 9: AI generated content detected by Binoculars before and after the release of ChatGPT.

## 6 Conclusion

We present the fourth NLLG arXiv report, highlighting the top 40 most influential papers in cs.CL, cs.AI, cs.LG and cs.CV. This includes 11 recently released highly cited papers and 7 further papers that gained influence over the past months. Notably, the focus lies on the creation of new foundation models and the search for newer, more efficient architectures. As this reports’ special focus, we compare the prevalence of AI generated content in the top-40 papers with random papers selected from arXiv. We find that the top papers tend to contain less markers of AI use, indicating that they are written by humans to a larger degree. Additionally, we find that previous key-words to detect AI use are declining in frequency, calling into question the longevity of detection methods. To be more reliable, these tools would need to be updated on a model basis, e.g., by using fresh generated text for mixed-model based approaches.
