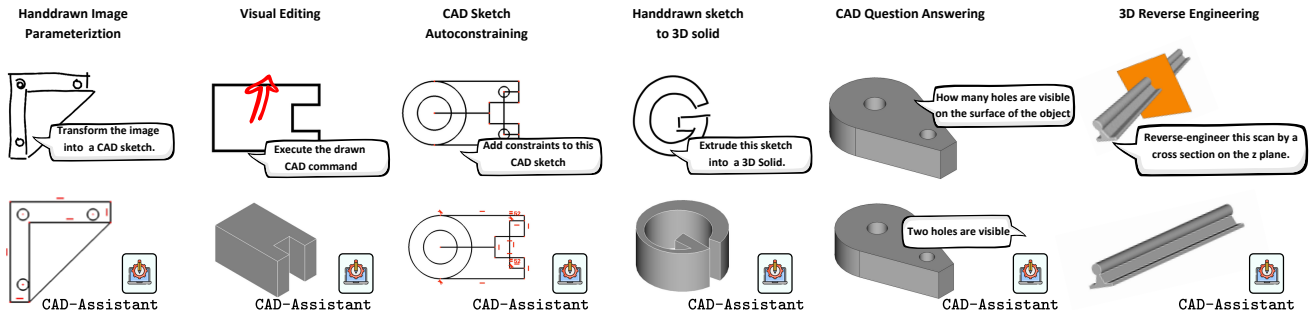

Figure 1. CAD-Assistant: A tool-augmented VLLM framework able to handle diverse CAD tasks in a zero-shot manner. Shown are examples of multimodal input queries and the corresponding responses generated by CAD-Assistant.

Abstract

We propose *CAD-Assistant*, a general-purpose CAD agent for AI-assisted design. Our approach is based on a powerful Vision and Large Language Model (VLLM) as a planner and a tool-augmentation paradigm using CAD-specific modules. *CAD-Assistant* addresses multimodal user queries by generating actions that are iteratively executed on a Python interpreter equipped with the FreeCAD software, accessed via its Python API. Our framework is able to assess the impact of generated CAD commands on geometry and adapts subsequent actions based on the evolving state of the CAD design. We consider a wide range of CAD-specific tools including Python libraries, modules of the FreeCAD Python API, helpful routines, rendering functions and other specialized modules. We evaluate our method on multiple CAD benchmarks and qualitatively demonstrate the potential of tool-augmented VLLMs as generic CAD task solvers across diverse CAD workflows.

1. Introduction

Computer-Aided Design (CAD) refers to the use of computer software to assist in the creation, modification, analysis, or optimization of a design [6]. CAD is crucial for enabling precise, efficient, and scalable design processes across industries. Recently, there has been a significant research interest in the automation of CAD pipelines. Examples include, 3D reverse-engineering [15, 25, 38, 56], CAD generation [49, 59, 62], edge parametrization [11, 71], CAD from multiview images [19, 67], hand-drawn CAD sketch parametrization [23, 24] and text-guided CAD editing [28]. Still, most efforts to date have centered around fixed workflows, and the development of CAD agents to address generic tasks in a zero-shot manner remains largely unexplored. In this work, we advocate that the creation of CAD agents capable of interacting with and supporting designers through the CAD development process would be a transformative advancement for the CAD industry, streamlining time-consuming design work and reducing the learning curve for CAD.

As Vision and Large Language Models (VLLMs) con-

continue to mature [3, 4, 14, 31, 33, 34, 39, 41], they hold promise for enabling AI-assisted CAD design, as their very vast pre-training and common sense reasoning allow for numerous downstream tasks without explicit fine-tuning on new domains. However, multiple factors may constrain their ability to interact with or be effectively integrated into CAD software [1, 2, 13]. We identify the following: (1) *Inability to understand visual programs*—as identified in prior work [46, 50], VLLMs may struggle to semantically interpret the appearance of rendered objects from their corresponding visual programs [46] or recognize the spatial arrangement and varied combinations of visual concepts [50]. These limitations constrain their capacity to comprehend CAD models and restrict their ability to generate or modify CAD visual programs. (2) *Unpredictable geometric effect of CAD Commands*—high-level CAD commands (e.g. applying geometric constraints) can have a complex effect on the geometry and topology of a CAD model [48, 49], determined by advanced CAD solvers. VLLMs might be unreliable in predicting the cumulative effect of generated CAD commands on a CAD design. (3) *Under-representation of CAD APIs in Training Corpora*—unlike widely used libraries (e.g. matplotlib and scikit-learn), CAD APIs are often diverse and poorly documented, with limited coverage in publicly available code, making their effective use by VLLMs challenging.

In this work, we propose CAD-Assistant, a generic CAD agent for AI-assisted CAD. Our framework enables zero-shot CAD design based on textual and visual prompting. CAD-Assistant is based on a VLLM planner and a tool-augmentation paradigm [18, 36, 55, 69], utilizing CAD-specific modules. The planner generates actions executed within a Python interpreter that integrates the open-source CAD software FreeCAD [13] as a core component via its Python API. We demonstrate that existing limitations of VLLMs in CAD can be addressed by the proposed CAD-Assistant through tool augmentation and CAD software integration as: (1) It achieves *enhanced visual program understanding* through a dedicated rendering and parameter serialization module, providing a multimodal representation of a CAD model. (2) It can *adapt dynamically to the current state of the CAD design* by executing CAD commands directly via their Python interface and refining its plan based on their impact on geometry. (3) By including CAD API documentation as context, it *overcomes VLLMs under-exposure to CAD APIs* and enhances their capability to generate CAD code accurately. CAD-Assistant leverages a wide range of CAD-specific modules to process multimodal inputs, including hand-drawn inputs, precise CAD sketches, and 3D scans.

The proposed tool-augmented VLLM framework poses a novel paradigm for AI-assisted CAD design. Built upon powerful VLLMs, specifically the GPT-4o model [41],

the CAD-Assistant is a *training-free* framework. It addresses user queries by generating CAD code following Python FreeCAD API, producing highly interpretable and editable outputs. It can be directly conditioned on both textual prompts and hand-drawn images, while CAD-specific tools enable interaction with diverse inputs like 3D scans. To enable multiple CAD-related tasks with CAD-Assistant, we explore the integration of a wide range of CAD-specific tools, including a hand-drawn image parametrization model [23], a 2D cross-section generator, rendering modules for multimodal CAD model understanding among other applications. Notably, the framework is highly extensible, requiring only a Python docstring to incorporate new CAD tools, thus enabling further capabilities. We showcase the effectiveness of the proposed CAD-Assistant on existing CAD tasks. Evaluations are reported for 2D / 3D CAD question answering, auto-constraining, and hand-drawn CAD sketch image parametrization, where the proposed CAD agent is prompted to solve the task in a zero-shot manner without providing additional demonstrations. Furthermore, we identify that existing CAD benchmarks may not fully capture the capabilities of our general-purpose CAD design framework and demonstrate diverse use cases of our approach, including hand-drawn sketch to 3D solid and 3D reverse engineering from 3D scans via cross-section parameterization. Examples responses of the proposed CAD-Assistant on diverse multimodal queries are depicted in Figure 1.

Contributions: The main contributions of this work can be summarized as follows:

1. CAD-Assistant, the first generic task solver for AI-assisted CAD. Our framework is training-free, leveraging both textual and visual prompts for multimodal AI-assisted CAD design. By integrating FreeCAD via its Python API, it generates accurate CAD commands and adapts dynamically to design changes, thus addressing existing limitations in VLLMs for CAD tasks.
2. We investigate visual program understanding in black-box VLLMs and identify that factors such as parameterization strategy and serialization format can enhance VLLMs’ ability to effectively interpret CAD programs.
3. Evaluation of CAD-Assistant on CAD sketch benchmarks including CAD question answering [46], hand-drawn sketch image parametrization [24] and sketch auto-constraining [49]. Moreover, we qualitatively demonstrate the effectiveness of our system design on diverse CAD use cases, including CAD solid creation from 2D sketches and reverse engineering cross-sections of 3D scans.

The rest of the paper is organized as follows; Section 2 reviews the related works. The CAD-Assistant framework is described in Section 3 and Section 4 presents con-

ducted evaluations on CAD benchmarks. Section 5 discuss future potential, research challenges and current limitations of tool augmented VLLMs for CAD and conclusions are provided in Section 6.

2. Related Work

Foundation Models for CAD: Recently, there has been increasing research interest in the use of foundation models on CAD-related applications. CAD-Talk [68] introduces a framework for semantic CAD code captioning using multi-view photorealistic renderings of CAD models along with part-segmentation, powered by foundation models [10, 27]. Taking a similar path, QueryCAD [26] proposes an open-vocabulary CAD part segmentation from images leveraging segmentation foundation models and LLMs to perform CAD-related question-answering for robotic applications. CADLLM [61] proposes a T5 [47] LLM finetuned on the SketchGraphs [48] dataset of 2D CAD sketches for sketch auto-completion. CadVLM [60] extends CADLLM to the visual domain, incorporating a visual modality for CAD sketch auto-completion, autoconstraining and image-guided generation. CADReparam [28] uses VLLMs to infer meaningful variation spaces for parametric CAD models, re-parameterizing them to enable exploration along design-relevant axes. Img2CAD [67] utilizes a VLLM to reverse engineer objects from images, predicting the specific CAD command types needed to model each part of the object accurately. Badagabettu *et al.* [5], focus on text-guided generation of CAD models as CADQuery code, while LLM4CAD [32] use a similar approach to generate 3D CAD models from text and image inputs. The CAD-Assistant departs from the aforementioned task-specific methods, as it is the first generic, training-free framework for zero-shot CAD-Assisted design via a tool-augmented VLLM paradigm.

Tool-augmented VLLMs: The invention and manipulation of tools towards overcoming physical limitations constitutes an undeniable manifestation of human intelligence [52]. Driven by the advanced reasoning and planning capabilities of LLMs and VLLMs, there has been growing interest in enhancing their performance via augmentation of external tools [18, 21, 36, 51, 55, 57, 65, 69]. The field is further propelled by the emergence of benchmarks, namely ScienceQA [35] and TabMWP [37], which are well-suited for evaluating tool-use effectiveness. Tool-use offers several benefits [45], such as reducing hallucinated knowledge [53], providing real-time information [36], enhancing domain expertise [40] and producing interpretable outputs by making intermediate steps explicit [18, 55]. Planning is commonly performed via instructions in natural language [18, 36] or Python code generation [21, 55], and toolset might include search engines [29, 36, 40], calculators [12, 43], external

APIs [44], vision modules [18, 55], Hugging Face models [51], Azure models [65] or llm created tools [9]. Despite the vast potential of tool-augmented LLMs and VLLMs for CAD-related applications, the space remains unexplored. To our knowledge, this work represents the first investigation on tool-augmented VLLMs for AI-assisted CAD.

VLLMs as Geometrical Reasoners: Towards advancing tool-augmented VLLMs for AI-assisted CAD, it is crucial for the VLLMs planner to semantically recognize and precisely identify and manipulate individual elements within the parametric geometry. This type of precision is an essential skill when interfacing with CAD software. Naturally, this raises the question: *Can large vision language models understand symbolic graphics programs?* In that direction, Yi *et al.* [66] explored incorporating symbolic structure as prior knowledge for enhancing visual question answering. More recently, Sharma *et al.* [50] examined visual program generation and recognition, showing that while shape generation often relies on memorizing prototypes from training data, shape recognition demands a deeper understanding of primitives.

Qi *et al.* [46] introduced SGPBench, a question-answering benchmark designed to assess the semantic understanding and consistency of symbolic graphics programs, including CAD models. This benchmark evaluates the extent of LLMs’ ability to semantically comprehend geometric structures. While [46] applied instruction tuning to improve visual program understanding, our work emphasizes general-purpose VLLMs, demonstrating that factors like serialization and parametrization strategies for formatting geometry and multimodal representation of a CAD model can significantly expand VLLMs’ capacity for visual program understanding.

3. The proposed CAD-ASSISTANT

3.1. General Framework

This section provides an overview of the CAD-ASSISTANT. Our framework comprises the following three components:

Planner: The planner \mathcal{P} is modelled by a VLLM capable of advanced reasoning. Following [21], on each timestep t , the planner analyses the current context c_t and generates a plan p_t and an action a_t that implements p_t . In this work, we employ GPT-4o as the core framework planner.

Environment: We utilize the Python interpreter as the primary environment \mathcal{E} for executing the generated action a_t at time t . Additionally, \mathcal{E} integrates CAD software [13] as a foundational component for AI-assisted CAD applications. On each timestep, t , the environment provides feedback e_t of the current state of the CAD design.

Tool Set: The CAD-ASSISTANT utilizes a set

Module Type	Module Description
 Python	Action format and logical operations.
 FreeCAD	Intergration with CAD software.
 Davinci [23]	hand-drawn sketch image to CAD.
 Sketch Recognizer	Renders sketch and plots parameters.
 Solid Recognizer	Renders a 3D CAD model and plots its parameters.
 Constraint Checker	Analyzes geometric constraints.
 Crosssection Extract	Generates an image of a cross section from a 3D mesh.

Table 1. Summary of CAD-specific modules used by the CAD-Assistant.

$\mathcal{T} = \{\mathcal{T}_i\}_{i=1}^N$ of N CAD-specific tools, suitable for AI-Assisted CAD. These include standard Python libraries, modules of the FreeCAD Python API [13] to interface CAD commands, and other useful CAD-specific tools and Python routines.

The CAD-ASSISTANT can be formalized as follows: Given a multimodal x_0 input user query, on each timestep t , the planner \mathcal{P} generates:

$$p_t \leftarrow \mathcal{P}(x_0; c_{t-1}, \mathcal{T}), \quad (1)$$

$$a_t \leftarrow \mathcal{P}(p_t; c_{t-1}, x_0, \mathcal{T}), \quad (2)$$

where p_t is the current plan in natural language, and a_t is the current action formulated as Python code. Then, the generated action a_t is executed on the framework’s environment:

$$(f_t, e_t) \leftarrow \mathcal{E}(a_t; e_{t-1}, \mathcal{T}, x_0), \quad (3)$$

where f_t is the output of the code execution, and e_t is the new state of the CAD design. Note that f_t can include both textual and visual outputs of the execution, *e.g.* list of CAD geometries in `.json` format or the rendering of the current state of the CAD object. Finally, the context is updated as:

$$c_{t+1} \leftarrow \text{concat}(f_t, \{c_s\}_{s=1}^t), \quad (4)$$

concatenating the previous context with the current code execution output and is supplied to \mathcal{P} for plan generation of timestep $t+1$. This process iterates for an arbitrary T number of steps until the planner \mathcal{P} concludes that the request x_0 has been successfully addressed. At that point \mathcal{P} generates p_T , a special TERMINATE plan, that indicates the completion of the CAD-ASSISTANT’s response. An example of a complete execution flow generated to respond to an autoconstraining prompt request is provided in Figure 2.

3.2. CAD-specific Tool-set

CAD-ASSISTANT includes a set of N CAD-specific tools or modules. Each tool is defined by its method signature and the docstring that disambiguates its use. Similar to [20], we rely solely on docstrings and do not include few-shot demonstrations on examined tasks. While task demonstrations are known to enhance VLLM performance [7], they can also introduce usage bias [20]. Furthermore, the selection of high-quality demonstrations becomes combinatorially intractable as the number of CAD commands and tools grows. More importantly, expecting CAD designers to create tailored examples for each unique use case is impractical, thus ultimately limiting the general nature of the CAD-ASSISTANT. Note that \mathcal{T}_i contains only the module signature rather than the full method code as in [21, 55] to minimize context size and dependency on module details.

Modules \mathcal{T}_i are instantiated via their Python interface with arguments generated by \mathcal{P} as part of the action a_t . Notably, actions are formulated as Python code, as in [21, 55], rather than the natural-language instructions advocated by recent works [18, 36]. This design choice allows for direct use of the FreeCAD API. Moreover, the generated action a_t can access the parameters of the CAD models’ state e_t and perform logical and computational operations, which is highly advantageous for design tasks. Our CAD-specific tool set includes the following, also summarized in Table 1:

FreeCAD API: CAD-Assistant is integrated with the open-source FreeCAD software [13] via the FreeCAD Python API. This API enables programmatic control over the majority of commands available to designers and access to the current state of the CAD design. In this work, we consider a range of components from the Sketcher and Part modules of the FreeCAD API, focusing on CAD sketching, the addition and manipulation of primitives, geometric constraints, and extrusion operations for constructing 3D solids. A summary of the exact classes, methods and class attributes of the FreeCAD API integrated with CAD-Assistant is provided in the supplementary.

Python: Beyond facilitating actions a_t , the planner can utilize Python as a tool to conduct essential logical and mathematical operations, such as calculating segment lengths, determining angles, and deriving parameter values.

Hand-drawn Image Parameterizer: To enable visual sketching, we employ a task-specific model for hand-drawn image parameterization [23]. This module extracts parameters and constraints as text, allowing CAD-Assistant to reuse primitive parameters for CAD code generation.

CAD Sketch Recognizer: We equip CAD-Assistant with a CAD sketch recognition utility. This routine returns both a summary of geometries and parametric constraints in `.json` format, along with a visual rendering of the CAD sketch. The rendered sketch image includes nu-

USER QUERY: Analyse the sketch to identify geometric relationships and apply parametric constraints.

PLAN: To analyze the sketch and apply the appropriate parametric constraints, I will first use the `sketch_recognizer` function to understand the current state of the sketch. Then I will use the `analyse_constraints` function to evaluate their validity and impact on the sketch before applying them.

$p_1 \leftarrow \mathcal{P}$

ACTION: Use the `sketch_recognizer` function to analyze the current state of the sketch.

```
# Use the sketch_recognizer function to analyze the current state of the sketch
sketch_recognizer(sketch)
```

$a_1 \leftarrow \mathcal{P}$

ENVIRONMENT: Execution Success

The sketch contains the following elements, serialized in JSON format:

```

    { "id": 99, "Type": "Line segment", "StartPoint": {"x": -8.4, "y":
      8.4}, "EndPoint": {"x": 8.4, "y": 8.4}, "isConstruction": false }
  ],
  "Constraints": []
}
```

$(f_1, e_1) \leftarrow \mathcal{E}$

PLAN: The sketch consists of several line segments and arcs forming a square with rounded corners. To ensure the sketch is fully constrained, I will apply the following constraints:

1. Coincident constraints to connect endpoints of adjacent geometries.
2. Horizontal and Vertical constraints for the straight line segments.
3. Equal constraints for the arcs to ensure they have the same radius.
4. Tangent constraints between the arcs and the line segments.

I will first analyse and apply the Coincident constraints.

$p_2 \leftarrow \mathcal{P}$

ACTION: Analyze and apply Coincident constraints to connect endpoints of geometries.

```
# Define Coincident constraints for connecting endpoints
coincident_constraints = [
  Sketcher.Constraint('Coincident', 0, SubRef.START.value, 15, SubRef.END.value),
  Sketcher.Constraint('Coincident', 0, SubRef.END.value, 13, SubRef.START.value),
  Sketcher.Constraint('Coincident', 1, SubRef.START.value, 9, SubRef.END.value),
  Sketcher.Constraint('Coincident', 1, SubRef.END.value, 11, SubRef.START.value),
  Sketcher.Constraint('Coincident', 2, SubRef.START.value, 11, SubRef.END.value),
  Sketcher.Constraint('Coincident', 2, SubRef.END.value, 13, SubRef.START.value),
  Sketcher.Constraint('Coincident', 3, SubRef.START.value, 15, SubRef.START.value),
  Sketcher.Constraint('Coincident', 3, SubRef.END.value, 9, SubRef.START.value),
  Sketcher.Constraint('Coincident', 4, SubRef.START.value, 7, SubRef.START.value),
  Sketcher.Constraint('Coincident', 4, SubRef.END.value, 6, SubRef.START.value),
  Sketcher.Constraint('Coincident', 5, SubRef.START.value, 7, SubRef.START.value),
  Sketcher.Constraint('Coincident', 5, SubRef.END.value, 6, SubRef.END.value)
]
# Analyze and apply constraints
for i, constraint in enumerate(coincident_constraints):
  is_valid, moves_geometries = analyse_constraint(sketch, constraint)
  if is_valid and not moves_geometries:
    sketch.addConstraint(constraint)
sketch.recompute()
```

$a_2 \leftarrow \mathcal{P}$

ENVIRONMENT: Execution Success

$e_2 \leftarrow \mathcal{E}$

PLAN: The Coincidents have been applied, ensuring that the loops are closed. Next, I will apply Horizontal and Vertical constraints to the straight line segments to maintain their orientation.

$p_3 \leftarrow \mathcal{P}$

ACTION: Apply Horizontal and Vertical constraints to the line segments.

```
# Define Horizontal and Vertical constraints
# Rest of the code here.
```

$a_3 \leftarrow \mathcal{P}$

⋮ (Rest of the steps)

PLAN: The sketch is now properly constrained.
TERMINATE.

$p_5 \leftarrow \mathcal{P}$

Figure 2. Execution flow for autoconstraining. CAD-Assistant utilizes the recognizer function for CAD sketch understanding and generates constraints in a chain-of-thought manner. The last two steps are omitted for clarity.

meric markers of the primitive ID overlaid on the rendered geometries. Motivated by [63], this approach enhances visual grounding for GPT-4o, *i.e.* its ability to associate visual content with the textual description of primitives.

3D Solid Recognizer: For CAD model recognition, we also incorporate a 3D solid recognizer that generates a `.json` summary of model parameters (for both sketch and extrusion operations) along with visual renderings of the 3D solid from four different angles, providing a multimodal representation of structure and geometry.

Constraint Checker: We include a dedicated function that evaluates the parameters of a parametric constraint to determine its validity and whether it causes movement in geometric elements. The constraint analyzer facilitates effective interaction with the CAD solver by assessing the impact of commands like parametric constraints on geometry.

Cross-section Extract: Cross-sections are critical components of CAD reverse engineering workflows [8]. CAD-Assistant includes a specialized routine for 2D cross-section images from 3D scans across 2D planes.

4. Evaluations

This section presents the evaluations performed to validate the efficacy of the proposed framework. We first conduct an investigation of VLLMs’ ability to recognize CAD design and explore prompting strategies for enhancing their performance (Section 4.1). We then evaluate the effectiveness of CAD-Assistant. As a generic framework, CAD-Assistant can be conditioned to perform a wide range of tasks related to CAD design. To showcase the diverse capabilities of our approach, we evaluate on three standard tasks for CAD, (1) CAD question answering (Section 4.2), (2) CAD sketch autoconstraining (Section 4.3) and (3) Hand-drawn CAD sketch parametrization (Section 4.4).

4.1. VLLMs for CAD Understanding

Effective recognition of a CAD model is an essential requirement for the development of generic CAD agents. Still, VLLMs might struggle to semantically recognize graphical programs [46, 50] without instruction tuning [46]. In this work, we redirect our focus to prompting strategies that can be used to enhance CAD program understanding for VLLMs without requiring additional training. Specifically, we investigate the following:

Parametrization Strategy: Parametric geometries can be represented by different sets of parameters. For instance, a line could use start and end points or an angle and length relative to a reference. We compare the implicit parametrization approach of [46] to the point-based primitive representation of [24]. We also explore over-parametrization, where an extended set of parameters is used per geometry, even if some parameters carry redundant information.

2D CAD SGPBench - Sketch in Textual Format		
Serialization	Parameterization	Accuracy
<i>SGPBench [46] format</i>		
Serialized Graph	Implicit	0.674
<i>Standardized CAD Sketch formats</i>		
DXF [22]		0.671
OCA [17]		0.707
<i>Serialization Strategy (Tabular formats)</i>		
CSV	Point-based	0.703
Markdown	Point-based	0.706
HTML	Point-based	0.710
<i>Serialization Strategy (Schema-embedded formats)</i>		
Serialized Graph	Point-based	0.744
JSON	Point-based	0.748
<i>Parameterization Strategy</i>		
JSON	Point-based	0.748
JSON	Overparameterized	0.747

2D CAD SGPBench - Sketch as a Rendering	
CAD Sketch Image Type	Accuracy
hand-drawn Sketch	0.616
Precise Rendering	0.754

Table 2. Investigation of prompting strategies for semantic CAD understanding. We report performance for GPT-4o in terms of accuracy on the 2D partition of SGPBench [46]. **(Top)** Impact of prompting strategies on CAD QA performance from a textual description of sketch geometry. **(Bottom)** Visual QA performance from hand-drawn and precise rendering of a CAD sketch.

Serialization Strategy: The serialization format that is used to convert the parametric geometry into text can impact the planner’s ability to understand the geometry. Motivated by recent work on text-based serialization methods for tabular data [16], we compare commonly used formats such as *CSV*, *Markdown*, *HTML*, and *JSON*.

To examine the impact of the above strategies on CAD program understanding, we experiment on the recently introduced CAD question answering benchmark SGPBench [46] with GPT-4o. This ablation is performed on the 2D subset of SGPBench, including semantic multiple choice questions on 2D CAD sketches from Sketch-Graphs [48]. GPT-4o is provided with a textual description of a 2D CAD sketch and tasked with answering a multiple-choice question about the design. In Table 2 **(top)**, we ablate the effect on the performance of the parameterization and serialization strategies used to parse the CAD sketch into a textual format. Firstly, we observe that schema-embedded

Method	Planner	2D	3D
SGPBench [46]	GPT-4 mini	0.594	0.737
	GPT-4 Turbo	0.674	0.762
	GPT-4o	0.686	0.782
CAD-ASSISTANT	GPT-4 mini	0.614	0.737
	GPT-4 Turbo	0.741	0.789
	GPT-4o	0.791	0.805

Table 3. Comparison for the proposed CAD-ASSISTANT to LLM baselines for CAD QA on the 2D and 3D subsets of SGPBench [46]. We report performance for multiple VLLM planners.

representation like *JSON* performs better than tabular formats. Note that this is in contrast with recent work [54], where *HTML* was identified as the optimal serialization for tabular data. Secondly, GPT-4o demonstrates high sensitivity to geometry parametrization. The implicit parametrization used in SGPBench [46] significantly under-performs compared to a point-based parametrization for geometric primitives as in [24]. Overall, using a *JSON* serialization along with the point-based parametrization from [24] leads to substantial improvements over the original SGPBench format and other text-based CAD sketch formats, such as *DXF* and *OCA*. While over-parameterizing the sketches results in a negligible drop in performance w.r.t. a point-based parameterization, we argue that it is safer to opt for over-parameterization as other tasks might benefit from it. Furthermore, as shown in Table 2 **(bottom)**, visual question answering surpasses the performance reported for text-based recognition. Following these findings, we equip the CAD-ASSISTANT with a recognizer module that generates an over-parameterized JSON of sketches and a rendering of 2D CAD sketch or 3D solid for multimodal recognition.

4.2. CAD-ASSISTANT: CAD Question Answering

CAD-ASSISTANT is able to interact directly with a CAD model via its integration with CAD software and is tasked with answering a question about the design. In this section, we evaluate the performance of the proposed framework for CAD QA on SGPBench [46]. Evaluation is performed on both the 2D subset of SGPBench and the 3D subset (using 3D CAD models from the DeepCAD dataset [62]). For this experiment, we do not provide the CAD code as part of the prompt as in [46]. Instead, the CAD sketch or model is pre-loaded into a FreeCAD project file, allowing CAD-ASSISTANT to utilize the FreeCAD integration and CAD-specific tools to understand the design and answer questions. This experimental setup simulates a real-world question-answering environment where a CAD designer can ask open-ended questions about the design to support the iterative design process. Results are reported in Table 3. For this experiment, we also report the perfor-

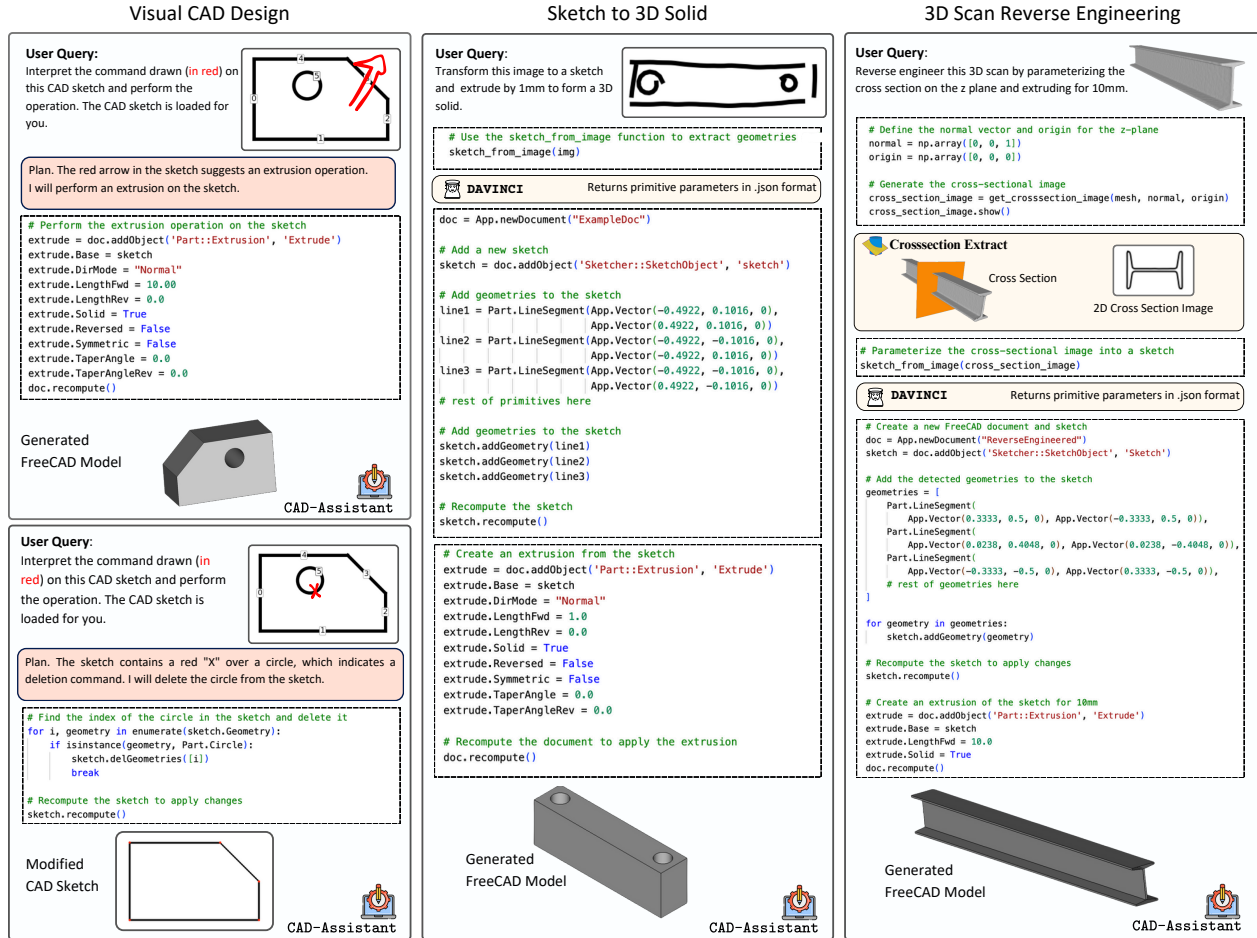

Figure 3. Examples of three real-world CAD use cases enabled by CAD-Assistant showcasing its multimodal CAD design capabilities.

mance of the GPT-4 mini and GPT-4 Turbo models as planners. We observe that by leveraging available tools such as the Python interpreter and the multimodal representations of sketches and CAD models generated via the recognizer routines, the CAD-Assistant improves QA performance for both CAD sketches and 3D CAD models, thus highlighting the potential of tool-use for CAD understanding. Notably, for the smaller GPT-4 mini, the performance gain from CAD-Assistant is marginally above (2D subset) or on-par (3D subset), emphasizing the need for pairing tool-augmented frameworks with a powerful VLLM.

4.3. CAD-Assistant: Autoconstraining

Parametric constraints are a key component of feature-based CAD modeling [38] and a widely adapted mechanism for explicit capturing of design intent [42, 70]. By applying constraints between geometric primitives, designers allow future modifications to propagate coherently across the design. In this section, we evaluate the CAD-Assistant for the task of CAD sketch auto-constraining [49]. Our framework is tasked with applying a set of parametric constraints

Method	Solve	PFI	CFI
<i>Task Specific Model</i>

Davinci [23]	×	0.836	0.489
Vitruvion [49]	✓	0.659	1.586
Davinci [23]	✓	0.789	<u>1.184</u>
CAD-ASSISTANT	✓	<u>0.784</u>	0.680

Table 5. Evaluation on the task of hand-drawn image parametrization. Comparison against the task-specific models of [23, 24, 49] in terms of *Acc* and *CD*.

constraint generation model Vitruvion [49], trained on the large-scale SketchGraphs [48] dataset of constrained CAD sketches. Note that the evaluation setting followed for auto-constraining [48, 49] commonly omits the application of a geometric solver (CAD software) that determines the final configuration of sketch primitives. Poorly parameterized constraints can distort the sketch geometry, as the solver may reposition primitives arbitrarily or fail altogether [49]. In this work, we include the impact of solving constraints on the overall performance.

Results are reported in Table 4. We adapt the evaluation metrics from [23]. Primitive F1 score (*PFI*) defines a true positive as a primitive with the correct type and parameters within five quantization units, and constraints are evaluated by Constraint F1 score (*CFI*), where a constraint is a true positive only if all associated primitives are also correctly predicted. Given the resource-intensive nature of GPT-4o API requests, we conduct inference on a subset of 700 CAD sketches from the test set of [48]. Notably, in Table 4, we observe that constraints generated by Vitruvion [49] can degrade sketch geometry if applied directly in CAD software without additional post-processing. The table presents the performance of CAD-ASSISTANT variants equipped with different tool subsets. We find that adding docstrings (*Docstr*) enhances performance over the GPT-4o baseline, with further improvements from the multimodal sketch recognizer (*MM-recog*) and the constraint checker (*Constr-Check*) that enable effectively recognizing the CAD sketch and interaction with CAD software to ensure the integrity of parametric constraints.

4.4. CAD-ASSISTANT: CAD Sketch Parameterization from Hand-drawn Image

In this section, we evaluate our framework for the task of hand-drawn image parameterization [23, 49]. CAD-ASSISTANT is equipped with an image parameterizer to process hand-drawn inputs and generate a textual description of primitives and constraints. Then, extracted parameters can be parsed into the corresponding FreeCAD API commands, whereas the use of the constraint analyzer can ensure the validity of applied constraints. We report hand-drawn parameterization performance compared

to task-specific models in Table 5 on the same test split as in Section 4.3. Note that we do not include a GPT-4o baseline as it underperforms for fine-grained localization tasks like primitive parameterization. Performance is measured in terms of accuracy (*Acc*) and chamfer distance (*CD*) as in [23, 24]. CAD-ASSISTANT is effective in translating the textually formatted parametrization of Davinci [23] into a FreeCAD sketch. Thanks to its dedicated constraint checker, it is able to filter out invalid or poorly parameterized constraints and generate a geometry close to the groundtruth as demonstrated by the reduction in CD.

5. CAD Agents: Future Potential, Challenges, and Current Limitations

This work positions tool-augmented VLLMs as a powerful paradigm for AI-assisted CAD, enhancing automation within real-world CAD workflows. Figure 5 showcases the potential of CAD-ASSISTANT to handle diverse CAD queries: (1) (*visual CAD design*) highlights the VLLM’s ability to semantically interpret visual prompts, effectively identifying CAD operations such as extruding a sketch or removing a primitive, (2) (*sketch to 3D solid*) demonstrates the capability to relate precise user queries to conceptual hand-drawn sketches, and effectively produce 3D solids, (3) (*3D scan reverse engineering*) showcases the ability to interpret 3D scans along with textual queries to perform cross-sections, parameterize features, and reconstruct CAD models from scans. These use cases show that tool-augmented VLLMs enable multimodal CAD design, a highly sought-after capability (*e.g.* [30]). The VLLM planner determines when it can interpret visual cues directly or if additional CAD-specific tools are needed to fulfill user requests.

A significant barrier to advancing generic CAD agents is the lack of evaluation benchmarks. Existing CAD-related benchmarks are designed to assess the performance of task-specific models on fixed workflows and are not be adequate for demonstrating the full potential of generic CAD agents. Developing CAD counterparts to [35, 37], *i.e.* CAD benchmarks suitable for assessing the effectiveness of general CAD agents, is identified as interesting future work.

Finally, throughout our investigation, we also identified some limitations of VLLMs as general planners for CAD. VLLM performance varies significantly across commands; for example, it may misinterpret arguments in radians versus sketch coordinates and can be sensitive to coordinate precision. Notably, CAD-ASSISTANT underperforms for the commonly reported task of CAD sketch autocompletion [49]. While adept at following well-defined prompts, it struggles with abstract requests like *complete the CAD sketch*, placing geometries without fully grasping design intent. This underscores the need for CAD-specific expertise, positioning VLLMs as supportive tools that enhance, rather than replace, an engineer’s design capabilities.

6. Conclusion

In this work, we introduce `CAD-Assistant`, a general-purpose CAD agent built on a VLLM planner and a tool-use paradigm of CAD-specific tools. Our framework responds to multimodal queries in a zero-shot manner via generated actions that are executed in a python interpreter, integrated with FreeCAD. We assess `CAD-Assistant` on diverse CAD benchmarks and qualitatively demonstrate the potential of tool-augmented VLLMs for the automation in real-world CAD workflows.

CAD-Assistant: Tool-Augmented VLLMs as Generic CAD Task Solvers?

Supplementary Material

This supplementary material includes various details that were not reported in the main paper due to space constraints. To demonstrate the benefit of the proposed CAD-Assistant, we also expand our qualitative evaluation.

8. Implementation Details

System Details: CAD-Assistant’s implementation is based on the Autogen [58] programming framework for Agentic AI. We report CAD-Assistant’s performance with gpt-4o-mini-2024-07-18, gpt-4-turbo-2024-04-09 and gpt-4o-2024-08-06 as VLLM planners, accessed via API calls. An overview of the CAD-Assistant framework is shown in Figure 4.

Datasets: For the qualitative evaluations reported in Section 4 of the main paper we consider the following datasets:

SketchGraphs: Quantitative evaluations for the autoconstraining and hand-drawn sketch parameterization tasks are performed on the SketchGraphs [48] dataset of constrained CAD sketches. We use the same test partition as in [49] and evaluate our framework on a subset of 700 constrained CAD sketches. For handdrawn synthesis we follow the strategy of [49], where handdrawn sketches are generated by subjecting primitives to random affine transformations and further augmenting them using a Gaussian process model.

SGPBench: Quantitative evaluations of CAD question answering are performed on SGPBench [46]. This is a recently introduced benchmark designed to evaluate semantic understanding of graphical programs. It consists of *program, question, multiple-choice answers* triplets and is divided into three subsets, each representing a distinct type of graphical program, i.e. SVG, CAD sketches, and 3D CAD models. The questions and answers are generated using GPT-4o and manually inspected for correctness. In this work, we focus on the 2D and 3D CAD subsets. The 2D CAD subset is derived from 700 CAD sketches from SketchGraphs [48], while the 3D CAD subset utilizes 1000 CAD models from the DeepCAD dataset [59].

9. CAD Representations

In this section, we formally introduce 2D CAD sketches and 3D CAD models as the primary CAD entities generated and manipulated by the proposed CAD-Assistant.

9.1. Constrained CAD Sketches

A constraint CAD sketch is commonly represented by a graph $\mathcal{G} = (\mathcal{P}^n, \mathcal{C}^m)$ comprising a set of n primitive nodes $\{\mathbf{p}_1, \mathbf{p}_2, \dots, \mathbf{p}_n\} \in \mathcal{P}^n$ and m edges between nodes $\{\mathbf{c}_1, \mathbf{c}_2, \dots, \mathbf{c}_m\} \in \mathcal{C}^m$ denoting geometric constraints. Primitives \mathbf{p}_i are of type line \mathbf{l}_i , arc \mathbf{a}_i , circle \mathbf{c}_i or points \mathbf{d}_i . VLLM and LLM planners can be sensitive to the parameterization strategy

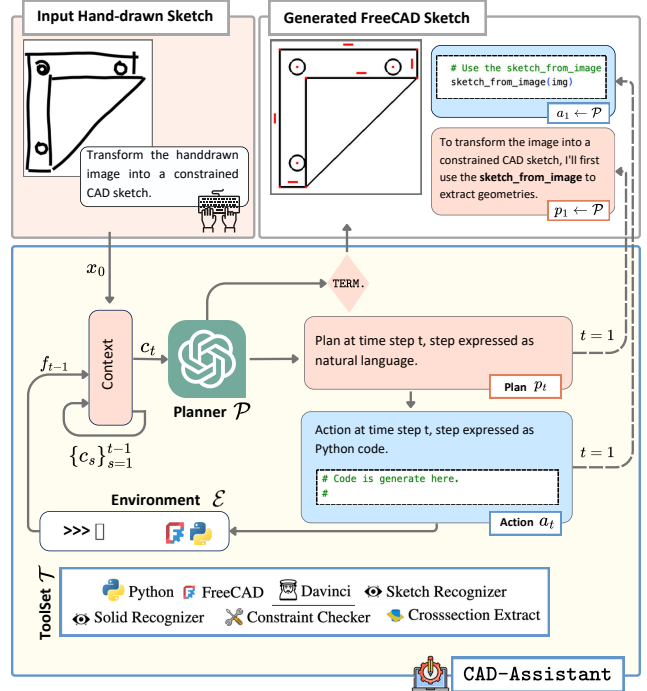

Figure 4. Overview of the CAD-Assistant framework. A multimodal user request is provided as context to a VLLM planner \mathcal{P} that responds with a plan p_t and an action a_t (python code). The action is executed on an environment \mathcal{E} equipped with FreeCAD, accessed via its python API. The output generated from the execution is then concatenated with the previously generated context and fed back to the planner, enabling the generation of the next iterative step. The execution terminates when a special TERMINATE plan is generated.

followed for representing \mathbf{p}_i . This work conducts an investigation on the impact of sketch parameterization on visual program understanding in black-box VLLMs presented in section 4.1 where we compare the following parameterization strategies:

Implicit: This is the parameterization strategy utilized for representation of 2D CAD sketches by the SGPBench [46]. Primitives \mathbf{p}_i are represented as follows:

$$\begin{aligned} \mathbf{a}_i &= (x_c, y_c, v_x, v_y, b_{wc}, \theta_s, \theta_e) \in \mathbb{R}^4 \times \{0, 1\} \times [0, 2\pi)^2 \\ \mathbf{c}_i &= (x_c, y_c, r) \in \mathbb{R}^3 \\ \mathbf{l}_i &= (x_p, y_p, v_x, v_y, d_s, d_e) \in \mathbb{R}^6 \\ \mathbf{d}_i &= (x_p, y_p) \in \mathbb{R}^2 \end{aligned}$$

Table 6. Implicit parameterization strategy for arcs \mathbf{a}_i , circles \mathbf{c}_i , lines \mathbf{l}_i and points \mathbf{p}_i .

where (x_c, y_c) denotes center point coordinates, (d_s, d_e)

are signed start/end point distances to a point (x_p, y_p) , the unit direction vector is denoted as (v_x, v_y) , radius is denoted with r , (θ_s, θ_e) are the start/end angles to the unit direction vector in radians and b_{wc} is a binary flag indicating if the arc is clockwise.

Point-based: We contrast the implicit parameterization to the point-based approach from [23, 24, 49] as described on the following table.

$\mathbf{a}_i = (x_s, y_s, x_m, y_m, x_e, y_e) \in \mathbb{R}^6$
$\mathbf{c}_i = (x_c, y_c, r) \in \mathbb{R}^3$
$\mathbf{l}_i = (x_s, y_s, x_e, y_e) \in \mathbb{R}^4$
$\mathbf{d}_i = (x_p, y_p) \in \mathbb{R}^2$

Table 7. Point-based parameterization strategy for arcs \mathbf{a}_i , circles \mathbf{c}_i , lines \mathbf{l}_i and points \mathbf{p}_i .

where (x_s, y_s) , (x_m, y_m) , (x_e, y_e) are start, middle and end point coordinates and r is the radius.

Overparameterized: This strategy is a simple combination of the implicit and point-based parameterization.

$\mathbf{a}_i = (x_c, y_c, v_x, v_y, x_s, y_s, x_m, y_m, x_e, y_e, b_{wc}, \theta_s, \theta_e) \in \mathbb{R}^{10} \times \{0, 1\} \times [0, 2\pi)^2$
$\mathbf{c}_i = (x_c, y_c, r) \in \mathbb{R}^3$
$\mathbf{l}_i = (x_p, y_p, v_x, v_y, d_s, d_e, x_s, y_s, x_e, y_e) \in \mathbb{R}^{10}$
$\mathbf{d}_i = (x_p, y_p) \in \mathbb{R}^2$

Table 8. Overparameterized parameterization strategy for arcs \mathbf{a}_i , circles \mathbf{c}_i , lines \mathbf{l}_i and points \mathbf{p}_i .

We identify the overparameterized strategy as the safest approach, as it enables the VLLM planner to leverage a broader and more diverse set of parameters, better accommodating the varying requirements of different input queries.

In addition to parametric primitives \mathbf{p}_i , a CAD sketch incorporates constraints defined by CAD designers, ensuring that future modifications propagate coherently throughout the design. A constraint is defined as an undirected between primitives \mathbf{p}_i and \mathbf{p}_j . They might also include subreferences $(s_i, s_j) \in \llbracket 1..4 \rrbracket^2$, to specify whether the constraint is applied on *start*, *end*, *middle* point, or *entire* primitive for both \mathbf{p}_i and \mathbf{p}_j . Note that some constraints may involve only a single primitive \mathbf{p}_i (e.g. a vertical line); in such cases, the constraint is defined as the edge between the primitive and itself. In this work we consider the following types of constraints: *coincident*, *parallel*, *equal*, *vertical*, *horizontal*, *perpendicular*, *tangent*.

9.2. CAD Models

Following the feature-based CAD modeling paradigm [38, 62], a CAD model $\mathbf{C} \in \mathcal{C}$ is constructed as a sequence of design steps. In this work, evaluation is performed on CAD models from the 3D partition of SGPBench [46] sourced from the DeepCAD dataset [62]. These models are constructed exclusively via a *sketch-extrude* strategy, where 2D CAD sketches \mathcal{G}_i are followed by extrusion operations that turns the sketch into a 3D volume. Extrusions include the following parameters:

Parameter Description	Parameter Notation
Sketch plane orientation	$(\theta, \phi, \gamma) \in [0, \pi] \times [0, 2\pi)^2$
Sketch plane translation	$(\tau_x, \tau_y, \tau_z) \in \mathbb{R}^3$
sketch scale	$\sigma \in \mathbb{R}$
Extrusion distance	$(d_-, d_+) \in \mathbb{R}^2$
Extrusion type	$\beta \in \{1, 2, 3, 4\}$

Table 9. Extrusion Parameters description.

where extrusion type β can be among *new*, *cut*, *join* and *intersect*.

9.3. Parameter Quantization

Unlike prior task-specific models for CAD-related tasks such as hand-drawn sketch parameterization [23, 24, 49], CAD sketch generation [49], or 3D CAD model generation [62], the CAD-ASSISTANT does not rely on the common practice of parameter quantization. Typically, these methods use a 6-bit uniform quantization scheme to convert continuous sketch and extrusion parameters into discrete tokens, enabling prediction through transformer-based sequence architectures trained with cross-entropy loss [23, 24, 49, 62]. In contrast, the CAD-ASSISTANT employs a VLLM planner that directly regresses primitive and extrusion parameters as continuous numerical values. We apply the 6-bit uniform quantization to the outputs of CAD-ASSISTANT, to facilitate direct comparisons with task-specific methods for auto-constraining and hand-drawn sketch parameterization reported on section 4.3 and 4.4 of the main paper.

10. CAD Benchmarks

We evaluate our framework on a diverse set of CAD on diverse set of CAD benchmarks including CAD question answering, autoconstraining, and hand-drawn sketch parameterization. This section provides formal problem statements and evaluation frameworks for these tasks.

10.1. CAD Question Answering

We report performance for CAD Question answering in Section 4.2 of the main paper. Evaluation is performed on both the 2D and 3D partitions of the SGPBench [46]. Formally, this multiple choice question answering task can be defined as performing the mapping $f : (\mathcal{P}_g, \mathbf{q}, \mathbf{A}) \rightarrow \tilde{\mathbf{a}} \in \mathcal{A}$, where \mathcal{P}_g is a graphical program, $\mathbf{q} \in \mathcal{Q}$ a question related to the rendered object of \mathcal{P} , $\mathbf{A} = \{\mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3, \mathbf{a}_4\}$ is the set of multiple-choice answers and $\tilde{\mathbf{a}}$ is the single predicted answer. Multiple-choice answers can be represented by the space of one-hot vectors as follows

$$\mathcal{A} \rightarrow \{\mathbf{a} \in \{0, 1\}^4 \mid \|\mathbf{a}\|_1 = 1\}. \quad (5)$$

For the 2D partition of SGPBench, \mathcal{P}_g becomes the input sketch graph \mathcal{G} and CAD-ASSISTANT performs the mapping $f_{2D} : (\mathcal{G}, \mathbf{q}, \mathbf{A}) \rightarrow \tilde{\mathbf{a}} \in \mathcal{A}$. For the 3D subset of SGPBench, our framework operates on CAD models from \mathcal{C} and performs $f_{3D} : (\mathbf{C}, \mathbf{q}, \mathbf{A}) \rightarrow \tilde{\mathbf{a}} \in \mathcal{A}$. Performance is measured in terms of prediction accuracy.

10.2. Autoconstraining

The CAD-Assistant is evaluated on CAD sketch autoconstraining in section 4.3 of the main paper. Given a set of n sketch primitives $\{\mathbf{p}_1, \mathbf{p}_2, \dots, \mathbf{p}_n\} \in \mathcal{P}^n$ the goal of autoconstraining is to infer a set of parametric constraints applied on these primitives or perform the mapping:

$$f_{constr} : \{\mathbf{p}_i\}_{i=1}^n \rightarrow \{\mathbf{c}_i\}_{i=1}^m \in \mathcal{C}^m, \quad (6)$$

to recover the complete sketch graph $\mathcal{G} = (\mathcal{P}^n, \mathcal{C}^m)$. As mentioned in section 9 each constraint is comprised of constraint type, participating primitives $\mathbf{p}_i, \mathbf{p}_j$ and subreferences (s_i, s_j) specifying the point of application (e.g. start, end, center).

Performance is measured in terms of Primitive F1 Score (*PF1*) and Constraint F1 Score (*CF1*) as in [64]. Note that the computation of both PF1 and CF1 is performed on quantized parameters (see section 9.3). *PF1* considers a true-positive to be a primitive with correctly predicted type and all parameters within 5 quantization units and a constraint relationship is considered a true-positive only if all involved primitives are also true-positives. Note that the CAD-Assistant predicts primitives and constraints as a permutation invariant set, thus correspondence w.r.t the ground truth is recovered prior to evaluation via Hungarian matching as in [24]. In this work, we solve the CAD sketch prior to evaluation as

$$\{\mathbf{p}_i^s\}_{i=1}^n = solve(\{\mathbf{p}_i\}_{i=1}^n, \{\mathbf{c}_i\}_{i=1}^m), \quad (7)$$

where \mathbf{p}_i^s is the solved parametric primitive whose parameterization can be altered by the solving operation performed by sophisticated CAD software.

10.3. Hand-drawn CAD sketch Parameterization

We report performance for CAD-Assistant on the problem of hand-drawn CAD sketch parameterization in Section 4.4 of the main paper. Given a binary sketch image $\mathbf{X} \in \{0, 1\}^{h \times w}$, where h and w denote the height and the width, CAD-Assistant performs the mapping

$$f_{param} : \mathbf{X} \rightarrow (\{\mathbf{p}_i\}_{i=1}^n, \{\mathbf{c}_i\}_{i=1}^m) \in \mathcal{G}, \quad (8)$$

by assembling CAD-specific tools. Binary images are of dimension 512×512 . For evaluation, we report parametric accuracy computed on quantized primitive tokens as in [24, 49] after solving the CAD sketch and recovering groundtruth correspondence as in the previous subsection. We also compute bidirectional Chamfer Distance (CD) on the image space. To that end we consider two sets of foreground pixel coordinates $Z = \{\zeta_n\}_{n=1}^{N_f}$ and $\hat{Z} = \{\hat{\zeta}_n\}_{n=1}^{\hat{N}_f}$ corresponding to the renderings of groundtruth and predicted CAD sketches, with N_f and \hat{N}_f being the cardinality of each set. Bi-directional chamfer distance is given by

$$CD = \frac{1}{2\hat{N}_f} \sum_{n=1}^{\hat{N}_f} \min_{\zeta_k \in Z} \|\hat{\zeta}_n - \zeta_k\|_2^2 + \frac{1}{2N_f} \sum_{n=1}^{N_f} \min_{\hat{\zeta}_k \in \hat{Z}} \|\zeta_n - \hat{\zeta}_k\|_2^2. \quad (9)$$

11. Costs

The proposed CAD-Assistant utilizes a GPT-4o planner accessed through API calls. Table 10 provides a summary of the costs associated with each user query across CAD benchmarks.

12. CAD-Assistant Prompts

In this work, we use a unified prompt template, similar to [21] for all CAD-specific problems. The prompt consists of three key components: (1) a general context, (2) a list of tools provided to the VLLM planner via docstrings, and (3) a multimodal user request. A summary of the FreeCAD API commands is provided in Table 11, and the full set of docstrings supplied to the planner is presented in Section 15. Note that as the set of considered API commands increases, the input context of the VLLM planner could increase. To address this, a preprocessing step could be implemented to dynamically select relevant docstrings before execution. The general context available to the VLLM planner is shown in Figure 6.

13. Qualitative Evaluation

This supplementary material presents examples of complete agent trajectories for the CAD benchmarks used in this study. Detailed examples from the 2D and 3D subsets of SGPBench are provided in subsections 14.1 and 14.2. Trajectories for the autoconstraining task are illustrated in subsection 14.3, while examples of hand-drawn parameterization are presented in subsection 14.4.

14. Beyond Simplified CAD Commands

This work focuses on a reduced set of CAD commands and operations as summarized on Table 11. These correspond to the subset typically covered by task-specific approaches for common CAD tasks, such as sketch generation [49] or CAD model generation [62]. Task-specific methods generally require extensive training on large CAD datasets, such as SketchGraphs [48] and DeepCAD [62]. As a result, their reported performance is limited to the CAD commands and primitives captured within these datasets. In this work, most of the experimentation was conducted on this reduced set of CAD commands to enable direct comparison with task-specific methods and evaluation on existing CAD benchmarks. However, the CAD-Assistant differs significantly as it is a train-free framework. It can operate across the diverse set of commands available within the FreeCAD API, requiring only a description of the command in the form of a docstring. This flexibility enables CAD-Assistant to generalize beyond the CAD command sets of task-specific datasets. We demonstrate qualitative examples of the proposed CAD-Assistant utilizing the CAD operation *Fillet* on Figure 5 (left) and forming a 3D solid via a *Revolution* Figure 5 (right). The CAD-Assistant is able to utilize both this commands by simply being provided with their documentation in the form of a docstring. Moreover, we find that VLLM planner performance might vary across CAD commands (section 5). This highlights the necessity of developing CAD-specific benchmarks tailored to CAD agents. Such benchmarks are crucial for gaining deeper insights into the capabilities and limitations of VLLM planners on generic CAD task solving.

Task	Avg Input Tokens	Avg Output Tokens	Avg Cost per User Request
CAD Question Answering	11280	178	\$0.0299
Autoconstraining	28422	852	\$0.0795
Handdrawn sketch parameterization	31170	1081	\$0.0887

Table 10. Cost per user request for the CAD-Assistant utilizing GPT-4o as VLLM planner.

USER QUERY: Apply a fillet on the 4 corners of this rectangle

```

sketch_recognizer(sketch)

# Define the radius for the fillet
radius = 2.0

# Calculate start points for the fillet at each corner
# Corner 1: Between line 0 and line 1
intersection_point_1 = sketch.Geometry[0].EndPoint
line0_direction = (sketch.Geometry[0].StartPoint - intersection_point_1).normalize()
line1_direction = (sketch.Geometry[1].EndPoint - intersection_point_1).normalize()
start_point1_0 = intersection_point_1 + line0_direction * radius
start_point1_1 = intersection_point_1 + line1_direction * radius

# Corner 2: Between line 1 and line 2
intersection_point_2 = sketch.Geometry[1].EndPoint
line1_direction = (sketch.Geometry[1].StartPoint - intersection_point_2).normalize()
line2_direction = (sketch.Geometry[2].EndPoint - intersection_point_2).normalize()
start_point2_1 = intersection_point_2 + line1_direction * radius
start_point2_2 = intersection_point_2 + line2_direction * radius

# Corner 3: Between line 2 and line 3
intersection_point_3 = sketch.Geometry[2].EndPoint
line2_direction = (sketch.Geometry[2].StartPoint - intersection_point_3).normalize()
line3_direction = (sketch.Geometry[3].EndPoint - intersection_point_3).normalize()
start_point3_2 = intersection_point_3 + line2_direction * radius
start_point3_3 = intersection_point_3 + line3_direction * radius

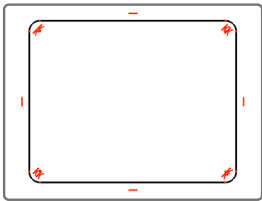

# Corner 4: Between line 3 and line 0
intersection_point_4 = sketch.Geometry[3].EndPoint
line3_direction = (sketch.Geometry[3].StartPoint - intersection_point_4).normalize()
line0_direction = (sketch.Geometry[0].EndPoint - intersection_point_4).normalize()
start_point4_3 = intersection_point_4 + line3_direction * radius
start_point4_0 = intersection_point_4 + line0_direction * radius

# Apply fillet at each corner
sketch.fillet(0, 1, start_point1_0, start_point1_1, radius, True, False)
sketch.fillet(1, 2, start_point2_1, start_point2_2, radius, True, False)
sketch.fillet(2, 3, start_point3_2, start_point3_3, radius, True, False)
sketch.fillet(3, 0, start_point4_3, start_point4_0, radius, True, False)

# Recompute the document to apply changes
doc.recompute()

```

Edited FreeCAD Sketch

USER QUERY: Create a sketch from this handdrawn image, add constraints and revolve it 360 degrees. Compute the revolution center so the radius is 1mm.

```

# Create a new FreeCAD document and sketch
doc = App.newDocument("RevolveSketch")
sketch = doc.addObject("Sketcher::SketchObject", 'Sketch')

# Add the extracted geometries to the sketch
line1 = Part.LineSegment(App.Vector(0.0078, 0.4922, 0), App.Vector(0.3359, 0.4922, 0))
line2 = Part.LineSegment(App.Vector(-0.3359, -0.1641, 0), App.Vector(0.0078, -0.1641, 0))
line3 = Part.LineSegment(App.Vector(-0.3359, -0.4922, 0), App.Vector(-0.3359, -0.1641, 0))
line4 = Part.LineSegment(App.Vector(-0.3359, -0.4922, 0), App.Vector(0.3359, -0.4922, 0))
line5 = Part.LineSegment(App.Vector(0.3359, -0.4922, 0), App.Vector(0.3359, 0.4922, 0))
line6 = Part.LineSegment(App.Vector(0.0078, -0.1641, 0), App.Vector(0.0078, 0.4922, 0))

# Add lines to the sketch
sketch.addGeometry(line1)
sketch.addGeometry(line2)
sketch.addGeometry(line3)
sketch.addGeometry(line4)
sketch.addGeometry(line5)
sketch.addGeometry(line6)

# Recompute the document to apply changes
doc.recompute()

# Constraints are added here
#

# Calculate the revolution center to achieve a 1mm radius
# The sketch is centered around the origin, so we need to offset the axis by 1mm
revolution_axis = (0.0, 1.0, 0.0) # Y-axis
revolution_base = (1.0, 0.0, 0.0) # Offset by 1mm along the X-axis

# Create the revolution
revolve = doc.addObject("Part::Revolution", "Revolve")
revolve.Source = sketch
revolve.Axis = revolution_axis
revolve.Base = revolution_base
revolve.Angle = 360.0
revolve.Solid = True

# Recompute the document to apply changes
doc.recompute()

```

Model generated on the FreeCAD software

Figure 5. Example of the proposed CAD-Assistant utilizing the *Fillet* and *Revolution* CAD commands. Like all examined commands, these can be executed by the framework, requiring only a docstring that clarifies their intended use. The figure shows only the generated code actions and the constraint generation code is omitted for clarity.

FreeCAD Class	Class Methods	Class Attributes
Sketcher.Sketch	<code>__init__()</code> , <code>recompute()</code> , <code>delGeometries(indx)</code> , <code>addConstraint(const)</code> , <code>addGeometry(geometry)</code>	<code>Name</code> , <code>Geometry</code> , <code>Constraints</code> , <code>State</code> , <code>ConstraintCount</code> , <code>GeometryCount</code> , <code>Placement</code>
Sketcher.Constraints	<code>__init__(constraintType, *args)</code>	<code>Name</code>
Part.Circle	<code>__init__(center, normal, radius)</code>	<code>Center</code> , <code>Radius</code>
Part.Point	<code>__init__(point)</code>	<code>X</code> , <code>Y</code> , <code>Z</code>
Part.ArcOfCircle	<code>__init__(circle, startParam, endParam)</code> , <code>__init__(startPoint, endPoint, midPoint)</code>	<code>Center</code> , <code>Radius</code> , <code>StartPoint</code> , <code>EndPoint</code> , <code>FirstParameter</code> , <code>LastParameter</code>
Part.LineSegment	<code>__init__(startPoint, endPoint)</code>	<code>StartPoint</code> , <code>EndPoint</code>
Part.Extrude	<code>__init__()</code>	<code>Base</code> , <code>DirMode</code> , <code>LengthFwd</code> , <code>LengthRev</code> , <code>Solid</code> , <code>Reversed</code> , <code>Symmetric</code> , <code>TaperAngle</code> , <code>TaperAngleRev</code>
Part.Solid	<code>fuse(shape)</code> , <code>cut(shape)</code> , <code>common(shape)</code>	<code>TypeId</code> , <code>Volume</code> , <code>BoundingBox</code>

Table 11. Summary of FreeCAD API classes, methods, and attributes utilized by the CAD-Assistant framework. The VLLM planner is supplied with docstrings that clarify their use, including detailed descriptions, function signatures and usage examples.

Prompt Template:

You are a helpful multimodal Computer Aided Design (CAD) AI assistant.

Solve tasks using your vision, coding, and language skills.

The task can be free-form or multiple-choice questions.

You can answer the user's question. If you are not sure, you can code.

You are coding in a Python jupyter notebook environment. The environment has also access to the PYTHON FREECAD API.

You can suggest python code (in a python coding block) for the user to execute. In a dialogue, all your codes are executed with the same jupyter kernel, so you can use the variables, working states in your earlier code blocks.

Solve the task step by step if you need to.

The task may require several steps. Give your code to the user to execute. The user may reply with the text and image outputs of the code execution. You can use the outputs to proceed to the next step, with reasoning, planning, or further coding.

When using code, you must indicate the script type in the code block. The user cannot provide any other feedback or perform any other action beyond executing the code you suggest. The user can't modify your code. So do not suggest incomplete code which requires users to modify. Don't use a code block if it's not intended to be executed by the user.

Don't include multiple code blocks in one response. Do not ask users to copy and paste the result. Instead, use 'print' function for the output when relevant. Check the execution result returned by the user.

For each turn, you should first do a "PLAN", based on the images and text you see.

Here are the commands that you can use. Call them as described by the following docstrings

<DOCSTRINGS>

The jupyter notebook has already executed the following code to import the necessary packages:

```
import sys
from PIL import Image
from tools import *
import math
import copy
import numpy as np
import FreeCAD as App
import Part, Sketcher
from enum import Enum

img = Image.open('handdrawn_image.png')
```

REQUIREMENTS #:

1. The generated actions can resolve the given user request # USER REQUEST # perfectly. The user request is reasonable and can be solved. Try your best to solve the request.
2. The arguments of a tool must be the same number, modality, and format specified in # DOCSTRINGS #;
3. If you think you got the answer, use ANSWER: <your answer> to provide the answer, and ends with TERMINATE.
4. All images should be stored in PIL Image objects. The user will send generated image outputs to you.
5. Only the FreeCAD commands that are provided to you. Do not used different commands or import new modules, as they will not be accessible.
6. Use as few tools as possible. Only use the tools for the use cases written in the tool description. You can use multiple tools in a single action.
7. You must return an answer with the choice letter if the user request is a multiple-choice question.

USER REQUEST # <REQUEST HERE>

Now please generate only PLAN and ACTION in RESULT. If no action needed, also reply with you answer and ends with TERMINATE in the RESULT:#

Figure 6. Prompt template for the CAD-Assistant. A detailed docstring disambiguating the use of the FreeCAD API and CAD-specific tools is provided as part of the prompt. The docstring is shown in section 15. On this example, the VLLM planner has a handdrawn sketch image preloaded. For different usecases, loading can be 3D scans or FreeCAD project files.

14.1. More qualitative results on CAD question answering for the 2D Subset of SGPBench.

USER QUERY: You are given a FreeCAD project file that includes a 2D CAD sketch. The FreeCAD project is already loaded for you.
Question: What is the position of the smallest rectangle relative to the largest rectangle?
 A) Above B) Below
 C) left D) right

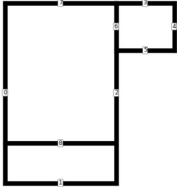

PLAN: To determine the position of the smallest rectangle relative to the largest rectangle in the sketch, I need to analyze the sketch. I will use the 'sketch_recognizer' function to get a JSON representation of the sketch's geometries and constraints, as well as a rendered image of the sketch. This will help me identify the rectangles and their relative positions.

ACTION:

```
# Use the sketch_recognizer function to analyze the current state of the sketch
sketch_recognizer(sketch)
```

ENVIRONMENT: Execution Success

Rendered Sketch Image

Returns primitive parameters in JSON format here.

PLAN: The JSON data and the rendered image show two rectangles. The largest rectangle is defined by the lines with IDs 0, 1, 2, and 7. The smallest rectangle is defined by the lines with IDs 3, 4, 5, and 6. The smallest rectangle is positioned to the right of the largest rectangle.

ANSWER: D, **TERMINATE**.

USER QUERY: You are given a FreeCAD project file that includes a 2D CAD sketch. The FreeCAD project is already loaded for you.
Question: How many right angles are present in the CAD object?
 A) Two B) Four
 C) Six D) Eight

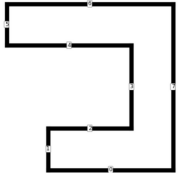

PLAN: To determine the number of right angles in the CAD object, I need to analyze the sketch. I will use the 'sketch_recognizer' function to obtain a JSON representation of the sketch's geometries and constraints, as well as a rendered image of the sketch. This will help me identify the number of right angles present in the object.

ACTION:

```
# Use the sketch_recognizer function to analyze the current state of the sketch
sketch_recognizer(sketch)
```

ENVIRONMENT: Execution Success

Rendered Sketch Image

Returns primitive parameters in JSON format here.

PLAN: The sketch consists of a series of connected line segments forming a shape. To determine the number of right angles, I need to examine the connections between these line segments. Each connection between two perpendicular lines forms a right angle. From the JSON data and the rendered image, I can identify the following right angles:

1. Between line segments 0 and 1
 2. Between line segments 1 and 2
 3. Between line segments 2 and 3
 4. Between line segments 3 and 4
 5. Between line segments 4 and 5
 6. Between line segments 5 and 6
 7. Between line segments 6 and 7
 8. Between line segments 7 and 0
- There are eight right angles in total.

ANSWER: D, **TERMINATE**.

USER QUERY: You are given a FreeCAD project file that includes a 2D CAD sketch. The FreeCAD project is already loaded for you.
Question: What type of triangle is shown in the image based on its side lengths?
 A) Equilateral B) Isosceles
 C) Scalene D) Right

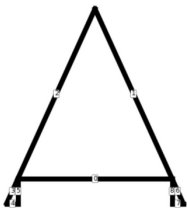

PLAN: To determine the type of triangle based on its side lengths, I need to examine the sketch and identify the lengths of its sides. I will use the 'sketch_recognizer' function to analyze the sketch and obtain a JSON representation of its geometric elements, which will help me understand the side lengths of the triangle.

ACTION:

```
# Use the sketch_recognizer function to analyze the current state of the sketch
sketch_recognizer(sketch)
```

ENVIRONMENT: Execution Success

Rendered Sketch Image

Returns primitive parameters in JSON format here.

PLAN: The sketch shows a triangle with three main line segments: 0, 1, and 2. I need to calculate the lengths of these segments to determine the type of triangle.

ACTION:

```
def calculate_length(start, end):
    return math.sqrt((end['x'] - start['x'])**2 + (end['y'] - start['y'])**2)

# Extract the start and end points of the triangle's sides
line_0 = ("start": {"x": -0.395, "y": -0.3723}, "end": {"x": 0.3956, "y": -0.3723})
line_1 = ("start": {"x": 0.3959, "y": -0.3728}, "end": {"x": 0.4004, "y": 0.4993})
line_2 = ("start": {"x": 0.0001, "y": 0.5}, "end": {"x": -0.3955, "y": -0.3721})

# Calculate the lengths of the sides
length_0 = calculate_length(line_0['start'], line_0['end'])
length_1 = calculate_length(line_1['start'], line_1['end'])
length_2 = calculate_length(line_2['start'], line_2['end'])

length_0, length_1, length_2
```

ENVIRONMENT: Execution Success

Output:
 (0.7906, 0.957590056, 0.9576313656)

PLAN: The lengths of the triangle's sides are approximately 0.7906, 0.9576, and 0.9576. Since two sides are equal, the triangle is isosceles.

ANSWER: B) Isosceles, **TERMINATE**

Figure 7. Complete agent trajectories of the CAD-Assistant for CAD Question Answering on the 2D subset of SGPBench.

14.2. More qualitative results on CAD question answering for the 3D Subset of SGPBench.

USER QUERY: You are given a FreeCAD project file that includes a 3D CAD model. The FreeCAD project is already loaded for you.
Question: What is the shape of the main body of the CAD object?
 A) Cylinder B) Sphere
 C) L-shape D) Cube

PLAN: To determine the shape of the main body of the CAD object, I need to analyze the 3D model in the FreeCAD project. I will use the 'solid_recognizer' function to get a visual representation and JSON serialization of the model's attributes. This will help me understand the shape of the object.

ACTION:

```
# Use the solid_recognizer to analyze the state of the loaded CAD document
solid_recognizer(doc)
```

ENVIRONMENT: Execution Success

Returns primitive parameters in JSON format here.

PLAN: The rendered image of the 3D model shows an L-shaped object. This matches the description of an L-shape, which is one of the options provided in the multiple-choice question.

ANSWER: C, **TERMINATE.**

USER QUERY: You are given a FreeCAD project file that includes a 3D CAD model. The FreeCAD project is already loaded for you.
Question: What is the primary shape of the top part of the CAD object?
 A) Square B) Triangle
 C) Circle D) Arch

PLAN: To answer the question about the primary shape of the top part of the CAD object, I need to examine the 3D CAD model. I will use the 'solid_recognizer' function to analyze the model and obtain a rendered image of the object. This will help me identify the primary shape of the top part.

ACTION:

```
# Use the solid_recognizer to analyze the state of the loaded CAD document
solid_recognizer(doc)
```

ENVIRONMENT: Execution Success

Returns primitive parameters in JSON format here.

PLAN: The rendered image of the 3D model shows that the top part of the CAD object has a curved shape, resembling an arch. The JSON data also indicates the presence of an arc in the sketch geometry, which supports this observation.

ANSWER: D) Arch **TERMINATE.**

USER QUERY: You are given a FreeCAD project file that includes a 3D CAD model. The FreeCAD project is already loaded for you.

Question: How many holes are visible on the flange of the CAD object?
 A) Two B) Three
 C) Four D) Five

PLAN: To determine the number of holes visible on the flange of the CAD object, I need to analyze the 3D model. I will use the 'solid_recognizer' function to get a visual rendering and JSON serialization of the CAD model, which will help me identify the number of holes

ACTION:

```
# Use the solid_recognizer to analyze the state of the loaded CAD document
solid_recognizer(doc)
```

ENVIRONMENT: Execution Success

Returns primitive parameters in JSON format here.

PLAN: The JSON data and the rendered image show that there are four circles in the sketches, which likely correspond to holes on the flange. The image confirms the presence of four holes.

ANSWER: C, **TERMINATE.**

USER QUERY: You are given a FreeCAD project file that includes a 3D CAD model. The FreeCAD project is already loaded for you.

Question: What basic geometric shape forms the primary body of the CAD object?
 A) Cylinder B) Cube
 C) Sphere D) Pyramid

PLAN: To determine the primary geometric shape of the CAD object, I need to analyze the 3D model. I will use the 'solid_recognizer' function to obtain a rendered image and JSON representation of the CAD model. This will help me identify the basic geometric shape.

ACTION:

```
# Use the solid_recognizer to analyze the state of the loaded CAD document
solid_recognizer(doc)
```

ENVIRONMENT: Execution Success

Returns primitive parameters in JSON format here.

PLAN: The rendered image shows a cylindrical shape as the primary body of the CAD object. The JSON data also indicates the presence of arcs and line segments that form circular profiles, which are extruded to create a cylindrical shape.

ANSWER: A, **TERMINATE.**

Figure 8. Complete agent trajectories of the CAD-Assistant for CAD Question Answering on the 3D subset of SGPBench.

14.3. More qualitative results on CAD sketch autoconstraining.

USER QUERY: Analyze the provided sketch to identify geometric relationships and apply the appropriate parametric constraints, ensuring that all elements are properly constrained according to design principles. The sketch object is already loaded for you. Use the Coincident, Parallel, Equal, Vertical, Tangent, Perpendicular and Horizontal constraints.

PLAN: To analyze the sketch and apply the appropriate constraints, I will first use the 'sketch_recognizer' function to understand the current geometries and constraints in the sketch. This will help me identify the geometric relationships and determine which constraints to apply

```

ACTION:
# Use the sketch_recognizer to analyze the state of the loaded CAD sketch
sketch_recognizer(sketch)
    
```

ENVIRONMENT: Execution Success

Rendered Sketch Image

Returns primitive parameters in JSON format here.

PLAN: The sketch contains multiple line segments, arcs, and points. To ensure the sketch is fully constrained, I will apply the following constraints: 1. Coincident constraints to connect endpoints of line segments and arcs. 2. Horizontal and vertical constraints for line segments that are aligned with the axes. 3. Parallel constraints for line segments that should remain parallel. 4. Perpendicular constraints for line segments that should be perpendicular. 5. Tangent constraints for arcs and line segments that should be tangent. I will analyze each constraint before applying it to ensure it is valid and does not move the geometries.

```

ACTION:
# Define constraints to be analyzed and potentially applied
constraints_to_analyze = [
  Sketcher.Constraint('Coincident', 0, SubRef.END.value, 1, SubRef.END.value),
  Sketcher.Constraint('Coincident', 1, SubRef.START.value, 3, SubRef.START.value),
  Sketcher.Constraint('Coincident', 3, SubRef.END.value, 2, SubRef.START.value),
  Sketcher.Constraint('Coincident', 2, SubRef.END.value, 4, SubRef.START.value),
  Sketcher.Constraint('Coincident', 4, SubRef.END.value, 8, SubRef.END.value),
  Sketcher.Constraint('Coincident', 8, SubRef.START.value, 9, SubRef.END.value),
  Sketcher.Constraint('Coincident', 6, SubRef.START.value, 9, SubRef.START.value),
  Sketcher.Constraint('Coincident', 9, SubRef.END.value, 7, SubRef.START.value),
  Sketcher.Constraint('Coincident', 7, SubRef.END.value, 0, SubRef.START.value),
  Sketcher.Constraint('Horizontal', 0),
  Sketcher.Constraint('Horizontal', 1),
  Sketcher.Constraint('Horizontal', 2),
  Sketcher.Constraint('Horizontal', 10),
  Sketcher.Constraint('Horizontal', 11),
  Sketcher.Constraint('Horizontal', 3),
  Sketcher.Constraint('Vertical', 4),
  Sketcher.Constraint('Vertical', 6),
  Sketcher.Constraint('Vertical', 7),
  Sketcher.Constraint('Vertical', 12),
  Sketcher.Constraint('Vertical', 13),
  Sketcher.Constraint('Parallel', 0, 1),
  Sketcher.Constraint('Parallel', 2, 10),
  Sketcher.Constraint('Parallel', 3, 12),
  Sketcher.Constraint('Parallel', 4, 13),
  Sketcher.Constraint('Perpendicular', 3, 2),
  Sketcher.Constraint('Perpendicular', 4, 2),
  Sketcher.Constraint('Tangent', 9, 6),
  Sketcher.Constraint('Tangent', 9, 7)
]

# Analyze and apply constraints
for i, constraint in enumerate(constraints_to_analyze):
  is_valid, moves_geometries = analyze_constraint(sketch, constraint)
  if is_valid and not moves_geometries:
    sketch.addConstraint(constraint)

sketch.recompute()
    
```

ENVIRONMENT: Execution Success

PLAN: The constraints have been successfully analyzed and applied without moving the geometries. The sketch should now be fully constrained according to the design principles. The sketch has been analyzed and the appropriate constraints have been applied. The sketch is now fully constrained with coincident, horizontal, vertical, parallel, perpendicular, and tangent constraints. **TERMINATE.**

USER QUERY: Analyze the provided sketch to identify geometric relationships and apply the appropriate parametric constraints, ensuring that all elements are properly constrained according to design principles. The sketch object is already loaded for you. Use the Coincident, Parallel, Equal, Vertical, Tangent, Perpendicular and Horizontal constraints.

PLAN: To analyze the sketch and apply parametric constraints, I will first use the 'sketch_recognizer' function to understand the current geometries and constraints in the sketch. This will provide a JSON representation and an image rendering of the sketch, which will help in identifying the geometric relationships and determining the necessary constraints.

```

ACTION:
# Use the sketch_recognizer to analyze the state of the loaded CAD sketch
sketch_recognizer(sketch)
    
```

ENVIRONMENT: Execution Success

Rendered Sketch Image

Returns primitive parameters in JSON format here.

PLAN: The sketch contains multiple circles and line segments. To ensure proper constraints, I will: 1. Apply Coincident constraints to ensure circles share centers where needed. 2. Apply Parallel constraints to line segments that should be parallel. 3. Apply Equal constraints to circles with the same radius. 4. Apply Vertical and Horizontal constraints to line segments that should be aligned accordingly. 5. Ensure loops are closed with Coincident constraints. I'll start by analyzing and applying Coincident constraints for shared centers and endpoints.

```

ACTION:
# Coincident constraints for shared centers
coincident_constraints = [
  Sketcher.Constraint('Coincident', 0, SubRef.CENTER.value, 1, SubRef.CENTER.value),
  Sketcher.Constraint('Coincident', 2, SubRef.CENTER.value, 5, SubRef.CENTER.value),
  Sketcher.Constraint('Coincident', 3, SubRef.CENTER.value, 4, SubRef.CENTER.value)
]

# Coincident constraints for endpoints to close loops
coincident_constraints += [
  Sketcher.Constraint('Coincident', 6, SubRef.START.value, 8, SubRef.START.value),
  Sketcher.Constraint('Coincident', 2, SubRef.END.value, 9, SubRef.START.value),
  Sketcher.Constraint('Coincident', 7, SubRef.START.value, 8, SubRef.END.value),
  Sketcher.Constraint('Coincident', 7, SubRef.END.value, 9, SubRef.END.value)
]

# Analyze and apply constraints
for i, constraint in enumerate(coincident_constraints):
  is_valid, moves_geometries = analyze_constraint(sketch, constraint)
  if is_valid and not moves_geometries:
    sketch.addConstraint(constraint)

sketch.recompute()
    
```

ENVIRONMENT: Execution Success

PLAN: The Coincident constraints have been successfully applied. Next, I will apply Parallel, Equal, Vertical, and Horizontal constraints. 1. Apply Parallel constraints to line segments that should be parallel. 2. Apply Equal constraints to circles with the same radius. 3. Apply Vertical and Horizontal constraints to line segments that should be aligned accordingly.

```

ACTION:
# Parallel constraints for line segments
parallel_constraints = [
  Sketcher.Constraint('Parallel', 6, 7),
  Sketcher.Constraint('Parallel', 8, 9)
]

# Equal constraints for circles with the same radius
equal_constraints = [
  Sketcher.Constraint('Equal', 0, 4),
  Sketcher.Constraint('Equal', 1, 2),
  Sketcher.Constraint('Equal', 2, 3)
]

# Vertical and Horizontal constraints
vertical_constraints = [
  Sketcher.Constraint('Vertical', 8),
  Sketcher.Constraint('Vertical', 9)
]

horizontal_constraints = [
  Sketcher.Constraint('Horizontal', 6),
  Sketcher.Constraint('Horizontal', 7)
]

# Analyze and apply constraints
for i, constraint in enumerate(parallel_constraints +
  equal_constraints +
  vertical_constraints +
  horizontal_constraints):
  is_valid, moves_geometries = analyze_constraint(sketch, constraint)
  if is_valid and not moves_geometries:
    sketch.addConstraint(constraint)

sketch.recompute()
    
```

ENVIRONMENT: Execution Success

PLAN: The constraints have been successfully applied, and the sketch is now fully constrained according to design principles. The sketch should now have proper geometric relationships and be robust against modifications. **TERMINATE.**

# Recognize the sketch to verify
sketch.recognizer(sketch)
    
```

ENVIRONMENT: Execution Success

Returns primitive parameters in JSON format here.

PLAN: The sketch has been successfully transformed with the geometries and constraints applied. The constraints were analyzed to ensure they are valid and do not move the geometries. The rendered image confirms the transformation. The hand-drawn image has been successfully transformed into a constrained CAD sketch in FreeCAD. All constraints were validated and applied without moving the geometries **TERMINATE.**

Constrained FreeCAD Sketch

Figure 10. Complete agent trajectories of the CAD-Assistant for handdrawn CAD sketch parameterization.

15. Docstrings

This section provides the complete docstring of the toolset available to the VLLM planner.

```
1 def sketch_recognizer(sketch: Sketch) -> None:
2     """Analyzes a 2D CAD sketch, providing both a JSON serialization of the Attributes for the geometry
3     and constraints and an image rendering of the sketch. Use this function to understand the current FreeCAD sketch.
4
5     This function processes the given sketch and returns a JSON representation describing its geometric
6     elements (e.g., lines, arcs, points, circles) and constraints from the `sketch.Geometry`
7     and `sketch.Constraints` lists. Attributes for Geometries and constraints are extracted directly from these lists,
8     serialized into a structured JSON format for easy interpretation.
9
10    Additionally, this function generates an image rendering of the sketch for visual examination. The sketch
11    is rendered as a black and white image. Primitives of the CAD sketch are labeled with a unique numerical ID,
12    shown by a marker that is positioned over the primitive.
13
14    Parameters:
15    -----
16    sketch (Sketch):
17        The input sketch object to be analyzed, containing the geometries and constraints.
18
19    Prints:
20    -----
21    Displays the sketch's parameters and constraints for quick review. It also returns a
22    sketch_image (PIL.Image.Image or np.ndarray) rendering of the sketch.
23
24    Usage Example:
25    -----
26    >>> sketch_recognizer(sketch)
27    The sketch contains the following geometries and constraints, serialized in JSON format:
28    {
29        "Geometry": [
30            {
31                "Index": 1,
32                "Type": "Line segment",
33                "StartPoint": {
34                    "x": ...,
35                    "y": ...
36                },
37                "EndPoint": {
38                    "x": ...,
39                    "y": ...
40                },
41                "isConstruction": ...
42            },
43            "Constraints": [
44                { ... }
45            ]
46        ]
47    }
48    Rendered image of the sketch:
49    [Image displays here]
50    """
51 def solid_recognizer(doc: App.Document) -> None:
52     """Analyzes a 3D CAD Model, providing both a JSON serialization of the Attributes for the geometry
53     and constraints and an image rendering of the sketch and extrude operations. Use this function to understand the current FreeCAD sketch.
54
55     This function processes the given sketch and returns a JSON representation describing its sketches and extrusions.
56     Attributes for Geometries and constraints are extracted directly from these lists,
57     serialized into a structured JSON format for easy interpretation.
58
59     Additionally, this function generates an image rendering of the 3D CAD model for visual examination. The sketch
60     is with multiple views.
61
62     Parameters:
63     -----
64     doc (App.Document):
65         The FreeCAD document including a list of Objects that can be sketch and extrusion operations
66
67     Prints:
68     -----
69     Displays the sketch and extrusion parameters for quick review. It also returns a
70     cad_image (PIL.Image.Image or np.ndarray) rendering of the sketch.
71
72     Usage Example:
73     -----
74     >>> solid_recognizer(sketch)
75     The 3D CAD model contains the following sketch and extrusion operations, serialized in JSON format:
76     {
77         "Sketch0": {
78             "Geometry": [
79                 {
80                     "Index": 1,
81                     "Type": "Line segment",
82                     "StartPoint": {
83                         "x": ...,
84                         "y": ...
85                     },
86                     "EndPoint": {
87                         "x": ...,
88                         "y": ...
89                     },
90                     "isConstruction": ...
91                 },
92                 "Constraints": [
93                     { ... }
94                 ]
95             },
96             "Extrusion1": { ... }
97         }
98     }
99     Rendered image of the 3D Model:
100    [Image displays here]
101    """
102
```

```

103
104 def sketch_from_image(img: PIL.Image.Image) -> None:
105     """Extracts a Sketch object from a given sketch image.
106
107     This function processes an input image and detects
108     parametric geometric primitives within the sketch (e.g., lines, circles, arcs, points) and the corresponding constraints. The function handle
109     input images as a PIL image. Detected geometric entities are printed and can be used for further analysis or manipulation.
110
111     Usage:
112     -----
113     This function is called a deep learning network that is imperfect and makes mistakes. Note that predicted constraints might be inaccurate and
114     applying them without analysing them might drastically change the sketch geometry. Use the provided 'analyse_constraint' function to make sure
115     that predicted constraints are valid and do not move geometric entities of the sketch.
116
117     Parameters:
118     -----
119     img (PIL.Image.Image or np.ndarray):
120         The input image of a handdrawn 2D CAD sketch.
121
122     Prints:
123     -----
124     A dictionary in JSON format containing the detected geometies and constraints.
125
126     Usage Example:
127     -----
128     >>> sketch_from_image(img)
129     The handdrawn parameterization tool detected the following sketch geometries and constraints, serialized in JSON format:
130     {
131     {
132         "Geometry": [
133         {
134             "Id": 1,
135             "Type": "Line segment",
136             "start_vector": {
137                 "x": ...,
138                 "y": ...
139             },
140             "end_vector": {
141                 "x": ...,
142                 "y": ...
143             },
144             "Constraints": [
145                 { ... }
146             ]
147         }
148         ]
149     }
150
151 def get_crosssection_image(mesh: o3d.geometry.TriangleMesh, normal: np.ndarray, origin: np.ndarray) -> PIL.Image.Image
152     """
153     Generates a 2D cross-sectional image from a 3D mesh.
154
155     This function takes a 3D mesh and extracts a cross-section based on a specified plane, defined by a normal vector
156     and an origin point. The extracted cross-section is then projected onto a 2D plane and normalized to a fixed size
157     suitable for visualization. The resulting image is centered, cropped, and rescaled to 128x128 pixels, capturing the
158     silhouette of the cross-section.
159
160     Parameters:
161     -----
162     mesh : o3d.geometry.TriangleMesh
163         The 3D mesh from which the cross-section will be extracted. It should contain vertices and faces attributes.
164     normal : np.ndarray, shape (3,)
165         The normal vector defining the orientation of the cross-sectional plane.
166     origin : np.ndarray, shape (3,)
167         A point on the plane to define its position in 3D space.
168
169     Returns:
170     -----
171     img : PIL.Image.Image
172         A grayscale PIL Image object of size 128x128 representing the 2D cross-section of the mesh.
173     """
174
175 def analyse_constraint(sketch: Sketch, constraint: Constraint) -> (bool, bool):
176     """Evaluate the impact of a given constraint on a sketch without applying it,
177     and determine if it causes significant changes to the geometry.
178
179     This function returns two binary flags: one indicating whether the constraint is valid,
180     and another indicating if it would cause geometries to move. Use this function to analyze
181     the effect of constraints on CAD geometries and ensure they behave as intended before
182     adding them to the sketch.
183
184     Parameters:
185     -----
186     sketch (Sketch):
187         The original FreeCAD sketch object containing geometric elements and constraints.
188     constraint (Constraint):
189         The constraint to be evaluated.
190
191     Returns:
192     -----
193     (is_valid, moves_geometries): (bool, bool)
194     - 'is_valid': 'True' if the constraint does not introduce conflicts or invalid states;
195     - 'False' if the constraint is invalid.
196     - 'moves_geometries': 'True' if the constraint causes movement of one or more geometries;
197     - 'False' if no significant movement occurs.
198
199     Prints:
200     -----
201     Displays a summary of the effect of the constraint on the geometric entities of the Sketch.Geometry list.
202     It also displays the is_valid and moves_geometries binary flags.
203
204
205

```

```

205 Usage:
206 -----
207 Use this function to test constraints before committing them to the sketch.
208 This allows you to detect unintended movements or conflicts early in the design process.
209
210 Example:
211 -----
212 >>> # Add a coincident constraint to align the start of geometry 1 with the end point of geometry 2.
213 >>> coincident_constraint = Sketcher.Constraint('Coincident', *(1, SubRef.START.value, 2, SubRef.END.value))
214
215 # You can analyse the effect the constraint would have on the sketch geometry
216 >>> is_valid, moves_geometries = analyse_constraint(sketch, coincident_constraint) # the function automatically prints an analysis of the constraint.
217 Analysis of Constraint[0] (without applying it to the sketch):
218 Type: Coincident
219 Elements:
220 - First: 1
221 - FirstPos: START
222 - Second: 2
223 - SecondPos: END
224 Movement:
225 Sketch.Geometry[5]:
226 - START moved from: (-0.500, -0.407) to (-0.297, 0.407)
227 Moves Geometries: True
228 IsValid: True
229 >>> is_valid
230 True
231 >>> moves_geometries
232 True
233
234 Note:
235 -----
236 This function does not modify the original sketch. It only provides a preview of the
237 potential impact of the given constraint.
238 """
239
240 class Sketch:
241     """Represents a 2D sketch object in FreeCAD, used for creating and defining geometric shapes,
242     constraints, and profiles that can later be referenced in 3D operations (e.g., extrusion, revolution).
243
244     The Sketch class provides methods to add, modify, and constrain geometric elements such as
245     lines, arcs, circles, and points. Sketches serve as essential building blocks in parametric
246     modeling, allowing users to control the relationships between elements through constraints.
247
248     Attributes:
249     -----
250     Name (str):
251         The name of the sketch object.
252     Geometry (List[Union[LineSegment, ArcOfCircle, Circle, Point]]):
253         A list of geometric elements in the sketch (e.g., lines, arcs, circles, points).
254     Constraints (List[Sketcher.Constraint]):
255         A list of constraints applied to the sketch elements (e.g., coincidence, equality, tangency).
256     ConstraintCount (int):
257         The total number of constraints applied to the sketch.
258     GeometryCount (int):
259         The total number of geometric elements present in the sketch.
260     Placement (Placement):
261         Defines the position and orientation of the sketch in 3D space. This attribute allows
262         the sketch to be moved or rotated within the document, affecting how it will be aligned
263         with other objects in FreeCAD.
264     State (List[str]):
265         A list representing the current status of the sketch. Possible values include:
266         - 'Touched': The sketch has been modified since the last update.
267         - 'Untouched': The sketch has not been modified since its last valid state.
268         - 'Invalid': The sketch contains errors or unsatisfied constraints.
269
270     Usage Example:
271     -----
272     >>> import FreeCAD
273     >>> from FreeCAD import Part, Sketcher
274     >>> doc = FreeCAD.newDocument("ExampleDoc")
275     >>> sketch = doc.addObject('Sketcher:SketchObject', 'sketch')
276
277     Methods:
278     -----
279     addGeometry(self, geometry: Union[LineSegment, ArcOfCircle, Circle, Point]) -> int:
280         This method is used to add a geometric element to the sketch.
281
282         Parameters:
283         -----
284         geometry:
285             a geometric element to be added on the sketch (e.g., lines, arcs, circles, points).
286
287         Returns:
288         -----
289         index (int):
290             The index of the added geometry on the sketch.Geometry list.
291
292     Usage Example:
293     -----
294     >>> line = Part.LineSegment(App.Vector(0.2, 0.3, 0), App.Vector(0.3, 0.2, 0))
295     >>> line_index = sketch.addGeometry(line) # A line is added.
296     >>> sketch.recompute()
297     >>> line = sketch.Geometry[line_index]
298
299     delGeometries(self, identifiers: List[int]) -> None:
300         Deletes one or more geometries from the sketch, based on their indices on the sketch.Geometry list.
301
302         Parameters:
303         -----
304         identifiers (List[int]):
305             A list of zero-based identifiers specifying which geometries to delete from the sketch.
306
307

```

```

307
308     Usage Example:
309     -----
310     >>> sketch.delGeometries([1]) # This will delete the geometry at index 1
311     >>> sketch.recompute()
312
313
314     addConstraint(self, constraint: Sketcher.Constraint) -> int:
315     Adds a constraint to the sketch.
316     Returns the index of the added constraint.
317
318     Parameters:
319     -----
320     constraint (Sketcher.Constraint):
321         a geometric constraint to be added on the sketch.
322
323     Returns:
324     -----
325     index (int):
326         The index of the added constraint on the sketch.Constraints list.
327
328     Usage Example:
329     -----
330     >>> parallel_constraint = Sketcher.Constraint('Parallel', 4, 6)
331     >>> sketch.addConstraint(parallel_constraint)
332     >>> sketch.recompute()
333
334     recompute(self) -> None:
335     Forces a recompute of the sketch to apply and update any pending changes.
336     This ensures that all modifications (such as added or deleted geometries and constraints)
337     are reflected in the document.
338
339     Parameters:
340     -----
341     None
342
343     Returns:
344     -----
345     None
346     """
347
348     class LineSegment:
349         """Represents a line defined by two endpoints in 3D space.
350         This class is part of the FreeCAD Part module and should be instantiated using `Part.LineSegment`.
351
352         Constructor:
353         -----
354         __init__(self, start_vector: App.Vector, end_vector: App.Vector)
355         Initializes a LineSegment with specified start and end points in 3D space.
356
357         Parameters:
358         -----
359         start_vector (App.Vector):
360             A 3D vector representing the coordinates of the line's start point.
361         end_vector (App.Vector):
362             A 3D vector representing the coordinates of the line's end point.
363
364         Attributes:
365         -----
366         StartPoint (App.Vector):
367             The start point of the line segment.
368         EndPoint (App.Vector):
369             The end point of the line segment.
370
371         Usage Example:
372         -----
373         >>> # Create a LineSegment from start and end points.
374         >>> start_point = App.Vector(0, 0, 0)
375         >>> end_point = App.Vector(1, 1, 1)
376         >>> line = Part.LineSegment(start_point, end_point)
377         >>> line.StartPoint.x
378         0 # access the x coordinate of the start point
379         """
380
381     class Circle:
382         """Represents a circle in 3D space defined by a center point, a normal vector and a radius using FreeCAD's Vector objects.
383         This class is part of the FreeCAD Part module and should be instantiated using `Part.Circle`.
384
385         Constructor:
386         -----
387         __init__(self, center_vector: App.Vector, normal_vector: App.Vector, radius: float):
388         Initializes a Circle with a specified center, normal vector, and radius.
389
390         Parameters:
391         -----
392         center_vector (App.Vector):
393             A 3D vector with the coordinates of the center point of the circle.
394         normal_vector (App.Vector):
395             A 3D vector representing the direction normal to the circle's plane.
396         radius (float):
397             The radius of the circle.
398
399         Attributes:
400         -----
401         Center : (App.Vector)
402             The center point of the circle.
403         Radius : (float)
404             The radius of the circle.
405
406         Usage Example:
407         -----
408         >>> center = App.Vector(6.0, 3.0, 0)
409         >>> normal = App.Vector(0, 0, 1)

```

```

410 >>> radius = 1.1
411 >>> circle = Part.Circle(center, normal, radius)
412 >>> circle.Center
413 Vector (6.0, 3.0, 0.0)
414 """
415
416 class Point:
417     """Represents a point in 3D space.
418     This class is part of the FreeCAD Part module and should be instantiated using `Part.Point`.
419
420     Constructor:
421     -----
422     __init__(self, point_vector: App.Vector):
423         Constructor of the Point class
424
425     Parameters:
426     -----
427     point_vector (App.Vector):
428         A 3D vector with the coordinates of the point.
429
430     Attributes:
431     -----
432     X (float):
433         The x-coordinate of the point.
434     Y (float):
435         The y-coordinate of the point.
436     Z (float):
437         The z-coordinate of the point.
438
439     Usage Example:
440     -----
441     >>> point = Part.Point(App.Vector(1.0, 2.0, 3.0))
442     >>> point.X
443     1.0
444     """
445
446 class ArcOfCircle:
447     """Represents a circular arc derived from a given circle, defined by start and end angles in radians.
448     The arc is drawn counterclockwise from the start angle to the end angle. Angles are expressed in radians
449     where 0 radians correspond to the positive x-axis and increase counterclockwise.
450
451     This class is part of the FreeCAD Part module and should be instantiated using `Part.ArcOfCircle`.
452
453     Constructor:
454     -----
455     __init__(self, circle: Circle, start_param: float, end_param: float)
456         Initializes an ArcOfCircle instance from a circle and specified start and end parameters.
457
458     Parameters:
459     -----
460     circle (Circle):
461         The Circle object from which the arc is derived.
462     start_param (float):
463         The starting parameter (angle in radians) on the circle's circumference that defines the beginning of the arc.
464     end_param (float):
465         The ending parameter (angle in radians) on the circle's circumference that defines the end of the arc.
466
467     Attributes:
468     -----
469     Radius : (float)
470         The radius of the circle from which the arc is derived.
471     StartPoint : (App.Vector)
472         The start point of the arc.
473     EndPoint : (App.Vector)
474         The end point of the arc.
475     Center : (App.Vector)
476         The center point of the circle from which the arc is derived.
477     FirstParameter : (float)
478         The start angle of the arc in radians.
479     LastParameter : (float)
480         The end angle of the arc in radians.
481
482     Usage Example:
483     -----
484     >>> #Create counterclockwise ArcOfCircle with center, radius, and start and end angles in radians.
485     >>> arc_center = App.Vector(0.0670, -0.0000, 0.0) # Center of the arc
486     >>> arc_radius = 0.0130 # Radius of the arc
487     >>> start_param = -1.6008 # Start parameter in radians
488     >>> end_param = -0.0000 # End parameter in radians
489     >>> arc_direction = App.Vector(0, 0, 1)
490     >>> # Create the arc using Part.ArcOfCircle
491     >>> arc = Part.ArcOfCircle(Part.Circle(arc_center, arc_direction, arc_radius), start_param, end_param)
492     """
493
494 class Arc:
495     """Represents an arc defined by a start point, an end point, and an intermediate point on the arc.
496
497     This class is part of the FreeCAD `Part` module and should be instantiated using `Part.Arc`.
498     The arc is uniquely determined by three points: the start, the end, and a point somewhere
499     on the arc (referred to as the midpoint, though it need not be the geometric middle). The
500     arc lies on the circle that passes through these three points.
501
502     After calling `recompute()` on a FreeCAD sketch, an `Arc` object is automatically
503     transformed into an `ArcOfCircle` object. This is because FreeCAD optimizes the
504     geometry representation for arcs, converting them to arcs of circles after
505     the geometry is fully processed.
506
507     Constructor:
508     -----
509     __init__(self, start_vector: App.Vector, end_vector: App.Vector, mid_vector: App.Vector)
510         Initializes a Arc with specified start, end and mid points in 3D space.
511
512     Parameters:
513     -----

```

```

514     parameters:
515     -----
516     start_vector (App.Vector):
517         A 3D vector representing the coordinates of the arc's start point.
518     end_vector (App.Vector):
519         A 3D vector representing the coordinates of the arc's end point.
520     mid_vector (App.Vector):
521         A 3D vector representing a point on the circumference of the arc.
522
523     Usage:
524     -----
525     Use this function to create ArcOfCircle objects from start, end and mid points.
526
527     Usage Example:
528     -----
529     >>> start_point = App.Vector(5.0, 0, 0)
530     >>> end_point = App.Vector(0, 5.0, 0)
531     >>> mid_point = App.Vector(3.54, 3.54, 0)
532     >>> arc = Part.Arc(start_point, mid_point, end_point)
533     <Arc object>
534     >>> sketch.addGeometry(arc)
535     >>> sketch.recompute()
536     >>> arc
537     <ArcOfCircle object>
538     """
539
540 class SubRef (Enum):
541     START = 1
542     END = 2
543     CENTER = 3
544
545 class Constraint:
546     """Represents a geometric constraint in a FreeCAD sketch.
547     Constraints define relationships between geometric elements (lines, arcs, circles, points), ensuring specific properties or behaviors.
548     Constraints can be created using the `Sketch.addConstraint()` method.
549
550     Constructor:
551     -----
552     __init__(self, constraint_type: str, *args)
553         Initializes a Sketcher.Constraint instance with a specified type and parameters.
554
555     Parameters:
556     -----
557     constraint_type (str):
558         The type of constraint to apply. Supported types include:
559         - 'Coincident'
560         - 'Parallel'
561         - 'Equal'
562         - 'Vertical'
563         - 'Horizontal'
564         - 'Perpendicular'
565         - 'Tangent'
566
567     *args (varies):
568         Additional parameters specific to the constraint type. These define the geometries or points
569         to which the constraint applies and any additional constraint-specific requirements.
570
571     Usage:
572     -----
573     Supported Constraint Types and Their Arguments:
574     1. Coincident: Enforces that two points or vertices coincide (i.e., share the same location in space).
575         - args: ('Coincident', First, FirstPos, Second, SecondPos)
576         - First (int):
577             The index of the first geometry.
578         - FirstPos (int):
579             The vertex (1 for start, 2 for end, 3 for center) of 'Geometry_index1' to fulfill the constraint.
580         - Second (int):
581             The index of the second geometry.
582         - SecondPos (int):
583             The vertex (1 for start, 2 for end, 3 for center) of 'Geometry_index2' to fulfill the constraint.
584
585     2. Parallel: Ensures two lines remain parallel.
586         - args: ('Parallel', First, Second)
587         - First (int):
588             The index of the first Line segment to be made parallel.
589         - Second (int):
590             The index of the second Line segment to be made parallel.
591
592     3. Equal: Makes two lines or circles equal in length or radius.
593         - args: ('Equal', First, Second)
594         - First (int):
595             The index of the first line segment or circle.
596         - Second (int):
597             The index of the first line segment or circle.
598
599     4. Vertical: Forces a line segment to be vertical.
600         - args: ('Vertical', First)
601         - First (int): The index of the Line segment.
602
603     5. Horizontal: Forces a line segment to be horizontal.
604         - args: ('Horizontal', First)
605         - First : (int)
606             The index of the line segment.
607
608     6. Perpendicular: Ensures that two line segments are perpendicular.
609         - args: ('Perpendicular', Geometry_index1, Geometry_index2)
610         - Geometry_index1 : (int)
611             The index of the first line segment.
612         - Geometry_index2 : (int)
613             The index of the second line segment.
614

```

```

615     7. Tangent: Makes a line tangent to a curve.
616     - args: ('Tangent', Geometry_index1, Geometry_index2)
617     - Geometry_index1 : (int)
618       The index of the first geometry.
619     - Geometry_index2 : (int)
620       The index of the first geometry.
621
622     Usage Example:
623     -----
624     >>> coincident_constraint = Sketcher.Constraint('Coincident', *(1, SubRef.START.value, 2, SubRef.END.value))
625     >>> sketch.addConstraint(coincident_constraint)
626     >>> sketch.recompute()
627     >>> sketch.State
628     ['Touched']
629     # Check the total number of constraints applied to the sketch.
630     >>> print(f"Number of constraints: {len(sketch.Constraints)}")
631     Number of constraints: 2
632     # Remove the most recently added constraint.
633     >>> sketch.delConstraint(len(sketch.Constraints) - 1)
634     # Remove the constraint on specific index.
635     >>> sketch.delConstraint(coincident_constraint_index)
636     >>> sketch.addConstraint(Sketcher.Constraint('Horizontal', 0))
637     >>> sketch.recompute()
638     >>> sketch.State # Use the State Variable to ensure that all added constraints are valid.
639     ['Touched', 'Invalid']
640     """
641
642 class Extrusion:
643     """Represents an extrusion of a sketch in FreeCAD.
644     This class is part of the FreeCAD Part module and should be instantiated using a sketch object and the desired extrusion parameters.
645
646     Attributes:
647     -----
648     Base (Sketch):
649         The sketch object that is extruded into a 3D solid.
650     DirMode (str):
651         Direction mode of the extrusion (default: "Normal").
652     LengthFwd (float):
653         Forward extrusion length.
654     LengthRev (float):
655         Reverse extrusion length.
656     Solid (bool):
657         Whether the extrusion is a solid (default: True).
658     Reversed (bool):
659         Whether the extrusion direction is reversed.
660     Symmetric (bool):
661         Whether the extrusion is symmetric along the sketch plane.
662     TaperAngle (float):
663         Taper angle for the extrusion.
664     TaperAngleRev (float):
665         Reverse taper angle for the extrusion.
666
667     Usage Example:
668     -----
669     >>> extrude = doc.addObject('Part::Extrusion', 'Extrude')
670     >>> extrude.Base = sketch # extrude an existing sketch object
671     >>> extrude.DirMode = "Normal"
672     >>> extrude.DirLink = None
673     >>> extrude.LengthFwd = 10.00
674     >>> extrude.LengthRev = 0.0
675     >>> extrude.Solid = True
676     >>> extrude.Reversed = False
677     >>> extrude.Symmetric = False
678     >>> extrude.TaperAngle = 0.0
679     >>> extrude.TaperAngleRev = 0.0
680     >>> doc.recompute()
681     """
682
683 class Solid:
684     """Represents a 3D solid in FreeCAD, created as part of an 'Extrusion' operation.
685     This shape object holds the geometry of the extruded solid and provides access to various
686     geometric properties, as well as methods for performing transformations and boolean operations
687     with other shapes.
688
689     Attributes:
690     -----
691     TypeId (str):
692         The type of shape, typically "Part::TopoShape".
693     Volume (float):
694         The volume of the extruded solid.
695     Area (float):
696         The total surface area of the extruded solid.
697     BoundBox (BoundingBox):
698         The bounding box of the shape, describing the spatial limits of the extrusion.
699
700     Methods:
701     -----
702     fuse(shape: Shape) -> Shape:
703         Performs a union operation, merging this shape with another solid to create a combined shape.
704
705         Parameters:
706         -----
707         shape (Shape):
708             The other solid shape with which to perform the union operation.
709
710         Returns:
711         -----
712         Shape:
713             A new solid object representing the union of this shape and the specified shape.
714
715     Usage Example:
716     -----
717     >>> shape1 = extrude1.Shape # Access the extruded shape

```

```

717     >>> shape1 = extrude1.Shape # Access the extruded shape
718     >>> shape2 = extrude2.Shape # Access the extruded shape
719     >>> result_shape = shape2.fuse(shape1) # Union with another shape
720
721 cut(shape: Shape) -> Shape:
722     Performs a cut operation, subtracting the specified shape from this shape.
723
724     Parameters:
725     -----
726     shape (Shape):
727         The solid shape to subtract from this shape.
728
729     Returns:
730     -----
731     Shape:
732         A new solid object representing the result of subtracting the specified shape from this shape.
733
734     Usage Example:
735     -----
736     >>> result_shape = shape1.cut(shape2) # Subtract shape2 from shape1
737
738 common(shape: Shape) -> Shape:
739     Performs an intersection operation, keeping only the volume that is common between this shape and another.
740
741     Parameters:
742     -----
743     shape (Shape):
744         The solid shape to intersect with this shape.
745
746     Returns:
747     -----
748     Shape:
749         A new solid object representing the intersected volume of the two shapes.
750
751     Usage Example:
752     -----
753     >>> result_shape = shape1.common(shape2) # Intersect shape1 with shape2
754     """

```
