*Abstract*—Sign Language Production (SLP) aims to generate sign videos corresponding to spoken language sentences, where the conversion of sign Glosses to Poses (G2P) is the key step. Due to the cross-modal semantic gap and the lack of wordaction correspondence labels for strong supervision alignment, the SLP suffers huge challenges in linguistics-vision consistency. In this work, we propose a Transformer-based Linguistics-Vision Monotonic Consistent Network (LVMCN) for SLP, which constrains fine-grained cross-modal monotonic alignment and coarse-grained multimodal semantic consistency in languagevisual cues through Cross-modal Semantic Aligner (CSA) and Multimodal Semantic Comparator (MSC). In the CSA, we constrain the implicit alignment between corresponding gloss and pose sequences by computing the cosine similarity association matrix between cross-modal feature sequences (*i.e.*, the order consistency of fine-grained sign glosses and actions). As for MSC, we construct multimodal triplets based on paired and unpaired samples in batch data. By pulling closer the corresponding textvisual pairs and pushing apart the non-corresponding text-visual pairs, we constrain the semantic co-occurrence degree between corresponding gloss and pose sequences (*i.e.*, the semantic consistency of coarse-grained textual sentences and sign videos). Extensive experiments on the popular PHOENIX14T benchmark show that the LVMCN outperforms the state-of-the-art.

*Index Terms*—Sign Language Production, Cross-modal Semantic Alignment, Multimodal Semantic Comparison.

#### I. INTRODUCTION

Sign language production plays a significant role in the deaf community as a rich form of visual language communication. Early works focus on avatar-based [\[1\]](#page-4-0) and statistical machine translation methods [\[2\]](#page-4-1). Recently, influenced by the excellence of deep learning, approaches based on CNN&RNN [\[3\]](#page-4-2)–[\[6\]](#page-4-3), GAN [\[7\]](#page-4-4), [\[8\]](#page-4-5) and VAE [\[9\]](#page-4-6), [\[10\]](#page-4-7) have emerged. Nowadays, a new common approach is to employ the Transformer framework to decode pose sequences [\[11\]](#page-4-8)–[\[17\]](#page-4-9).

Existing methods suffer huge multi-model semantic gaps due to the lack of robust supervised cross-modal alignment labeling. Although cross-modal semantic consistency has been noted in sign language translation [\[18\]](#page-4-10)–[\[21\]](#page-4-11), it has not been addressed in SLP, which needs to generate complex visual semantics from weak text. Nowadays, in many downstream tasks such as cross-modal retrieval [\[22\]](#page-4-12)–[\[26\]](#page-4-13), vision-language understanding [\[27\]](#page-4-14)–[\[30\]](#page-4-15), multimodal sentiment analysis [\[31\]](#page-4-16)– [\[35\]](#page-4-17), researchers tackle the rich multimodal data through the alignment and comparison of cross-modal semantics.

Therefore, we propose a Linguistics-Vision Monotonic Consistent Network (LVMCN) for SLP, which constrains sign linguistic-visual cues from both fine-grained cross-modal monotonic alignment and coarse-grained multimodal semantic consistency. As shown in Figure [1,](#page-1-0) the LVMCN is designed based on a Transformer framework that consists of a Cross-modal Semantic Aligner and a Multimodal Semantic Comparator. Firstly, the textual and visual semantic features considered as original gloss and pose sequences are extracted from gloss encoder and pose decoder of LVMCN respectively. Next, the semantic features obtained above are simultaneously inputted into the CSA and MSC. We automatically constrain the implicit alignment between the corresponding gloss and pose sequences by calculating the cosine similarity correlation matrices to solve the problem of inconsistent semantics of sign glosses and actions. Meanwhile, we construct multimodal triples from paired and unpaired batch data samples in the MSC. Semantic co-occurrence between gloss and pose sequences is enhanced by aligning corresponding text-visual pairs and separating non-corresponding ones, further improving the consistency of multimodal cues in SLP.

Compared with previous approaches, our main contributions are summarised below: (1) The proposed CSA constructs monotonic alignment of fine-grained cross-modal sequences in forward (linguistics-to-vision) and reverse (visionto-linguistics). (2) The designed MSC constructs multimodal triples according to the sentence-video matching relationships in the sample data to constrain semantic consistency between coarse-grained textual sentences and sign videos within batch data. (3) The constructed framework incorporates alignment loss  $\mathcal{L}_{ali}$  and comparison loss  $\mathcal{L}_{com}$ , in conjunction with classical fitting loss  $\mathcal{L}_{acc}$ , to jointly optimize the SLP task.

## II. METHOD

As illustrated in Figure [1,](#page-1-0) we proposed LVMCN is constructed based on a Transformer framework (see Section [II-A\)](#page-0-0), which includes two key modules: Cross-modal Semantic Aligner (CSA) (see Section [II-B\)](#page-1-1) and Multimodal Semantic Comparator (MSC) (see Section [II-C\)](#page-1-2).

## <span id="page-0-0"></span>*A. Transformer-based SLP Framework*

To explore gloss semantic features, we build a transformerbased encoder. We apply a linear embedding layer to map

<sup>\*</sup> Corresponding author.

<span id="page-1-0"></span>Fig. 1. Overview of LVMCN framework. It contains two key modules: Cross-modal Semantic Aligner (CSA) and Multimodal Semantic Comparator (MSC).

glosses into a high-dimensional space and a positional coding layer to capture temporal order, formulated as:

$$
x'_n = W^g \cdot x_n + b^g + PE(n), \tag{1}
$$

where  $x_n$  is a one-hot vector of the *n*-th gloss over the gloss vocabulary  $V$ ,  $PE$  is conducted by the sine and cosine functions on the temporal gloss order as in [\[12\]](#page-4-18), and  $W<sup>g</sup>$  and  $b<sup>g</sup>$  represent the weight and bias respectively.

Then, we use Multi-Head Attention (MHA), Normalisation Layer (NL) and Feedforward Layer (FL) to capture the global semantics of the glosses, *i.e.*,  $\tilde{x}'_{1:N} = NL(FL(MHA(x'_{1:N}))$ .

Similar to the gloss encoding, we encode the sign poses into a high-dimensional feature space through a linear layer and a positional encoding layer  $PE'$ , formulated as:

$$
y'_m = W^p \cdot y_m + b^p + PE'(m), \tag{2}
$$

where  $y_m$  denotes the coordinates of the pose at m-th time stamp;  $W^p$  and  $b^p$  represent the weight and bias respectively.

Our pose decoder is recursive that predicts the next pose  $\tilde{y}_{1:m}$  by aggregating all previously generated poses  $\tilde{y}_{m+1}$ . This process is formulated as follows:

$$
\tilde{y}_{m+1} = PoseDecoder(y'_{1:m}, \tilde{x}_{1:N}) \n\Leftrightarrow \begin{cases}\nz_m = FL(MHA_1(y'_{1:m}) + \tilde{y}_m), m \in [1, M]; \\
\tilde{y}_{m+1} = FL(MHA_2(z_m, \tilde{x}_{1:N})),\n\end{cases}
$$
\n(3)

where  $MHA_1$  and  $MHA_2$  are the two layers of pose decoder.

Pose Optimization: In the training stage, the Mean Absolute Error (MAE) loss is used to constraint the consistency of the produced poses  $\{\tilde{y}\}_{m=1}^M$  and the ground truth  $\{\hat{y}\}_{m=1}^M$ .

$$
\mathcal{L}_{acc} = \frac{1}{M} \sum_{m=1}^{M} |\tilde{y}_m - \hat{y}_m|.
$$
 (4)

# <span id="page-1-1"></span>*B. Cross-modal Semantic Aligner (CSA)*

To achieve cross-modal monotonic matching between gloss and pose sequences, we design a fine-grained semantic aligner. Specifically, we automate the constraints on the implicit alignment between the corresponding gloss and pose sequences by computing the cosine similarity correlation matrices between the textual features  $\{\tilde{x}\}_{n=1}^{N}$  and the visual features  $\{z\}_{m=1}^{M}$  to achieve accurate fine-grained cross-modal sequence monotonic alignment. In practice, we first normalize the textual features  $\{\tilde{x}\}_{n=1}^N$  and visual features  $\{z\}_{m=1}^M$ , formulated as:

$$
t_n = Normalize(\tilde{x}_n); v_m = Normalize(z_m).
$$
 (5)

We compute the match between  $t_n$  and  $v_t$  by cosine similarity and propose a textual visual semantic best matching function  $\mathcal{H}(V, T)$ , which finds the closest item from sequence  $V = \{v_1, v_2, \cdots, v_M\}$  for each item in sequence  $T =$  $\{t_1, t_2, \dots, t_N\}$ . The calculation process can be expressed as:

$$
\begin{cases}\n\mathcal{H}(V,T)_m = \operatorname*{argmax}_{M} (h(v_m, t_n)); \\
\phi(V,T) = \frac{1}{M} \sum_{m=1}^{M} h(v_m, \mathcal{H}(V,T)_m),\n\end{cases} \tag{6}
$$

where  $h(\cdot, \cdot)$  denotes cosine similarity. The result of  $\phi(V, T)$  is the video-text similarity, which finds the most similar textual feature for each visual feature. We also calculate the text-video similarity  $\phi(T, V)$  with the function  $\mathcal{H}(T, V)$ .

Alignment Optimization: For a batch containing  $B$  textvideo pairs  $\{V_i, T_i\}_{i=1}^B$ , the alignment loss is defined as:

$$
\mathcal{L}_{ali} = -\frac{1}{B} \sum_{i=1}^{B} (log \frac{\exp(\phi(V_i, T_i)/\tau)}{\sum_{j=1}^{B} \exp(\phi(V_i, T_j)/\tau)} + log \frac{\exp(\phi(T_i, V_i)/\tau)}{\sum_{j=1}^{B} \exp(\phi(T_i, V_j)/\tau)}) \tag{7}
$$

where  $\phi(V_i, T_j)$  denotes the similarity of the *i*-th video to the j-th text, and  $\phi(T_i, V_j)$  denotes the similarity of the *i*-th text to the j-th video. The temperature  $\tau$  determines the degree of alignment between the gloss and pose sequences.

# <span id="page-1-2"></span>*C. Multimodal Semantic Comparator (MSC)*

To ensure global semantic consistency between textual sentences and sign videos, we propose a coarse-grained multimodal semantic comparator, which brings "positive" textvisual pairs closer together and pushes "negative" ones farther away in the metric space. Specifically, we first calculate the

<span id="page-2-2"></span>

distance between gloss sequences  $T = \{t_1, t_2, \dots, t_N\}$  and pose sequences  $V = \{v_1, v_2, \cdots, v_M\}.$ 

<span id="page-2-0"></span>
$$
d(VT) = \frac{V^{\top}T}{\|V\| \|T\|} = L_2(V)^{\top} \cdot L_2(T) = VT, \quad (8)
$$

where  $d(VT)$  is the similarity score between features V and  $T, L_2$  denotes  $L_2$ - normalisation. Since the feature sequences V and T have been  $L_2$ -normalised in CSA, the direct multiplication here is the similarity score of the sample pairs.

Then, we construct multimodal triplets from the batch data as  $\mathcal{T} = \{(V_i T_i)^+, (V_i T_j)^-, (V_j T_i)^-\}$ , where  $(V_i T_i)^+$  represents a positive pair and  $(V_iT_j)^-$  and  $(V_jT_i)^-$  represent negative pairs. The distance measurement for positive and negative feature pairs must satisfy the following constraint:

$$
\begin{cases} d(V_iT_i)^+ > d(V_iT_j)^- + \sigma; \\ d(V_iT_i)^+ > d(V_jT_i)^- + \sigma; \end{cases}
$$
\n(9)

where  $\sigma$  controls the strength of comparison.

**Comparison Optimization:** For a batch containing  $B$  textvideo pairs  $\{V_i, T_i\}_{i=1}^B$ , we divide the multimodal triplets  $\mathcal{T} = \{(V_i T_i)^+, (V_i T_j)^-, (V_j T_i)^-\}$  into  $\mathcal{M} = \{V_i^0, T_i^+, T_j^-\}$  and  $\mathcal{N} = \{T_i^0, V_i^+, V_j^-\}$ , where  $\mathcal M$  is used for text-visual comparisons and  $N$  is used for visual-text comparisons. So the total comparison loss of the batch can be represented by:

$$
\mathcal{L}_{com} = -\sum_{k \in K} \left( \sum_{m \in \mathcal{M}} h_m^k \log(p_m^k) + \sum_{n \in \mathcal{N}} h_n^k \log(p_n^k) \right), \tag{10}
$$

where K is a unit matrix of dimension B and  $p_m^k$  and  $p_n^k$  are the results of Eq. [8,](#page-2-0)  $h_m$  and  $h_n$  represent one-hot coding of sample targets in triples  $M$  and  $N$  respectively.

In the end, to train the model in an end-to-end manner, the full objective function in this work is given as follows:

$$
\mathcal{L} = \alpha \mathcal{L}_{acc} + \beta \mathcal{L}_{ali} + \gamma \mathcal{L}_{com}, \qquad (11)
$$

where  $\alpha$ ,  $\beta$  and  $\gamma$  are hyperparameters of equilibrium loss.

# III. EXPERIMENTS

## *A. Experimental Settings*

Dataset and Evaluation Metrics. Following existing works [\[13\]](#page-4-19)–[\[15\]](#page-4-20), [\[17\]](#page-4-9), we evaluate our method on the German sign corpus PHOENIX14T [\[38\]](#page-4-25), which is a widely used SLP dataset. Besides, the NSLT [\[38\]](#page-4-25) is adopted as an offline backtranslation evaluation tool. To measure the quality of our method we used BLEU, ROUGE, WER, DTW-P, FID and MPJPE, which are the most popular metrics in the SLP field.

Implementation Details. Since PHOENIX14T does not provide 3D skeleton labels, following [\[13\]](#page-4-19), [\[15\]](#page-4-20), we use OpenPose [\[39\]](#page-4-26) to extract 2D joint coordinates. A skeletal correction model [\[5\]](#page-4-27) is applied to convert 2D positions into 3D coordinates, which are regarded as the target pose. We build LVMCN in the transformer modules with 2 layers and 4 heads, where the embedding size is set to 512. In addition, we apply a Gaussian noise onto pose coordinates and the noise rate is set to 5. During training, we use the Adam optimizer with a learning rate  $1 \times 10^{-3}$  and set  $\alpha = 1.0$ ,  $\beta = 1 \times 10^{-7}$ ,  $\gamma = 1 \times 10^{-5}$ ,  $\tau = 0.01$ ,  $\sigma = 0.05$ . Our code implemented PyTorch on NVIDIA GeForce RTX 2080 Ti GPU.

# *B. Comparison with State-of-the-Arts*

As shown in Table [I,](#page-2-1) LVMCN performs prominent superiority to all the other methods. Compared with the transformerbased baseline PT-base, our method improves 16.26% and 14.86% for BLEU-1 on DEV and TEST, respectively. And compared with the upgraded transformer method PT-GN, our method is still superior in all metrics, such as WER (reducing by 19.99%/21.07%). For the graph-based models, NAT-AT and NAT-EA have just reported the TEST set experimental results. Compared with the best version NAT-EA is obviously far behind ours (weakening 2.70% on BLEU-4). Besides, our method outperforms another transformerbased method DET too (raising 9.44%/8.60% for ROUGE on DEV/TEST). Furthermore, compared with D3DP-sign, G2P-DDM and GCDM, which are based on the most popular diffusion modeling method, our method also achieves better performance on TEST set (enhances 7.82%/8.22%/2.30% on BLEU-1 and 4.11%/1.86%/1.45% on BLEU-4). In the end, we compare with the best-performing method GEN-OBT. Only the DTW-P is slightly worse 0.07 on TEST, while all other metrics are substantially higher than those of the GEN-OBT.

Fig. 2. Visualization examples of produced pose sequence. We compare our LVMCN with PT-GN and GEN-OBT. Here, (a) show that LVMCN generates close-to-natural arm poses under labeling errors, while (b) show the cases that LVMCN fits the original frame better than ground-truth.

<span id="page-3-1"></span>TABLE III ABLATION RESULTS OF PARAMETERS ON PHOENIX14T.

<span id="page-3-0"></span>

Methods			<b>DEV</b>		<b>TEST</b>				
		$B1+$	WERt	FID.	B1↑	WER	FIDJ		
	0.01	25.79	76.86	1.94	24.33	75.43	2.16

	1.00	22.00	80.78	2.13	21.86	79.64	2.31		
$\sigma$	0.01	24.25	80.73	2.04	23.05	80.42	2.24		
	0.05	25.79	76.86	1.94	24.33	75.43	2.16		
	0.10	24.30	77.24	1.95	22.08	76.97	2.19		

## *C. Ablation Study*

Ablations of Modules. Table [II](#page-2-2) shows the ablation results of CSA and MSC. We set a transformer-based baseline w/o CSA&MSC, in which the poses are generated only under  $L_{acc}$  constraint. w/o CSA refers to MSC is applied into baseline, which enhances 0.45%/1.27% BLEU-1 and reduces 1.89%/2.14% WER on DEV/TEST, respectively. w/o MSC refers to CSA is applied into baseline, which leads to obvious improvement too (*e.g.*, 1.96% BLEU-1, 0.14 FID on TEST). Moreover, our method Full (Ours) achieves the best performance in all back-translation metrics, which indicates that the introduced CSA and MSC improve cross-modal semantic associations between linguistic and visual cues.

Analysis of Parameters. Table [III](#page-3-0) shows ablation results of parameters, containing the similarity  $\tau$  and contrast  $\sigma$  during training. We gradually increase the above parameters to test and the results show that our model performs best when  $\tau =$ 0.01 and  $\sigma = 0.05$ .

#### *D. Qualitative Results*

Visualization of Generated Example. Figure [2](#page-3-1) provides the pose examples generated by the PT-GN [\[13\]](#page-4-19) and GEN-OBT [\[14\]](#page-4-24) to demonstrate the superiority of the LVMCN. For examples (a) with noise labels labelling the original video blur, our method generates poses that are closest to natural. For the poses shown with pose labels (b) that deviate from the original video, our LVMCN generates poses that are more realistic than PT-GN and GEN-OBT and are closer to the real video.

Instantiation of Fine-grained Alignment. Figure [3](#page-3-2) shows example of cross-modal fine-grained alignment in CSA. As shown in this figure, the highly responsive attention regions are diagonally distributed in the attention map proving that our model achieves fine-grained semantic monotonic alignment. Additionally, we observe that some adjacent highly

(b) Example 2- Glosses: NORDWEST ZWEI SONST REGION MINUS FUENF ZWISCHEN EINS ZWISCHEN (during the day plus two degrees in the north-west otherwise minus five to plus one degree)

<span id="page-3-2"></span>Fig. 3. The result of fine-grained alignment in the CSA.

responsive attention regions temporally overlap, which is a reasonable phenomenon. On the one hand, consecutive smallamplitude movements will represent multiple discrete sign language words, and our model excels at fine-grained semantic alignment, which results in multiple glosses corresponding to adjacent poses (blue box). On the other hand, LVMCN can capture multiple words with semantic continuity, causing overlapping high-response attentional regions (green box).

#### IV. CONCLUSIONS

This work proposes a linguistics-vision monotonic consistent network for SLP, which includes a fine-grained Crossmodal Semantic Aligner (CSA) and a coarse-grained Multimodal Semantic Comparator (MSC). Specifically, CSA computes a similarity matrix to align sign glosses with actions. MSC constructs multimodal triples from paired and unpaired data, improving semantic consistency by bringing corresponding text-visual pairs closer and separating non-corresponding ones. Experiments validate the effectiveness of the method.
