Abstract-The recent emergence of the Segment Anything Model (SAM) enables various domain-specific segmentation tasks to be tackled cost-effectively by using bounding boxes as prompts. However, in scene text segmentation, SAM can not achieve desirable performance. The word-level bounding box as prompts is too coarse for characters, while the characterlevel bounding box as prompts suffers from over-segmentation and under-segmentation issues. In this paper, we propose an automatic annotation pipeline named Char-SAM, that turns SAM into a low-cost segmentation annotator with a Characterlevel visual prompt. Specifically, leveraging some existing text detection datasets with word-level bounding box annotations, we first generate finer-grained character-level bounding box prompts using the Character Bounding-box Refinement (CBR) module. Next, we employ glyph information corresponding to text character categories as a new prompt in the Character Glyph Refinement (CGR) module to guide SAM in producing more accurate segmentation masks, addressing issues of over-segmentation and under-segmentation. These modules fully utilize the bbox-to-mask capability of SAM to generate highquality text segmentation annotations automatically. Extensive experiments on TextSeg validate the effectiveness of Char-SAM. Its training-free nature also enables the generation of high-quality scene text segmentation datasets from real-world datasets like COCO-Text and MLT17.

Index Terms—Scene Text Segmentation, SAM, Visual Prompt

I. INTRODUCTION

In the field of scene text research, tasks such as detection [2], [3], recognition [4], [5], spotting [6], [7], processing [8],

[9], VQA [10], [11], and understanding [12], [13] are included. In addition, scene text segmentation has also gradually gained attention. Compared with word-level bounding boxes, scene text segmentation [1], [14]–[19] generates fine-grained pixellevel masks that are more beneficial for downstream tasks, including scene text erasure [20] and scene text editing [21]. However, the expensive cost of pixel-level annotations results in an extreme lack of high-quality datasets for scene text segmentation.

Due to the labor-intensive annotation, pseudo-annotated datasets are often utilized for training scene text segmentation models. For instance, COCO_TS [15] and MLT_S [17] are derived from scene text detection datasets COCO-Text [22] and MLT17 [23] respectively. However, the previous pseudo-

annotation process predominantly employs semi-supervised algorithms and suffers from fragmented text masks and misclassification of non-text pixels. These issues underscore the necessity of developing a scene text segmentation annotation pipeline that wields both high performance and low expense.

As a powerful prompt-based vision foundation model for image segmentation, Segment Anything Model (SAM) [24] can accurately segment objects of interest in an image based on diverse user-input prompts, including point, bounding box, text, and mask. By learning from a large volume of highquality masks in the SA-1B dataset [24], SAM obtains superior generalizability across various domains. Therefore, many recent works have migrated the ability of SAM to domainspecific segmentation tasks such as medical segmentation [25], [26], anomaly segmentation [27] and remote sensing segmentation [28], achieving remarkable performance.

However, applying SAM directly to scene text segmentation reveals two main issues in TextSeg [1] images: 1) Insufficient Prompt Granularity. Solely providing word-level bounding boxes is insufficient for SAM to segment individual characters accurately. As shown in Figure 1(a), SAM treats characters as a united entity rather than separate ones. Therefore, characterlevel bounding box prompts are required, as illustrated in Figure 1(b). 2) Over- and Under-segmentation. Even with a character-level bounding box, SAM struggles to distinguish the hole area (background area surrounded by foreground area) from the text area, resulting in over-segmentation in the hole area, as shown in Figure 1(c). This issue arises because the masks in SA-1B [24] with holes only account for a small part, while many text characters contain hole areas such as 'D', 'A', etc. Additionally, Figure 1(d) shows that the segmentation output of SAM could obtain an incomplete mask, especially when text characters are of large scale.

Based on the above observations and analysis, we propose a framework named **Char-SAM**, which derives from the **Char**acter-level visual prompt **S**egment **A**nything **M**odel. The overall pipeline consists of the Character Bounding-box Refinement (**CBR**) module and Character Glyph Refinement (**CGR**) module. The **CBR** module refines word-level annotations to more fine-grained character-level annotations, and the **CGR** module employs glyph information of text characters to tackle over-segmentation and under-segmentation. Noteworthy, the whole process is training-free. Extensive experiments show that the proposed framework achieves competitive performance and outperforms other methods for generating text segmentation annotations, demonstrating the generality of our proposed approach. The main contributions of this paper can be summarized as follows:

- Leveraging the powerful segmentation ability of SAM, we propose a novel automatic annotation pipeline Char-SAM for scene text segmentation via character-level visual prompts, without any external training process.
- To adapt the scene text segmentation task, CBR and CGR modules are designed to obtain fine-grained prompts and solve over-/ under-segmentation issues respectively.
- Based on real-world datasets COCO-Text and MLT17, we generate character-level text segmentation datasets COCO_TS_refined and MLT_S_refined, which benefits the performance for scene text segmentation.

II. METHOD

A. Framework

Char-SAM aims to refine word-level annotations corresponding to scene images into pixel-level annotations. As illustrated in Figure 2, the input composes of an input image $I \in \mathbb{R}^{H \times W \times 3}$, word bounding boxes $B = \{b_i\}_{i=1}^n$ and text transcriptions $T = \{t_i\}_{i=1}^n$, where b_i is the *i*-th input word bounding box and t_i indicates the corresponding transcription. The CBR module aims to obtain the precise character-level bounding boxes B_{tmp} and its corresponding character categories C_{tmp} . The refined character bounding boxes are regarded as the visual prompts P_{char} . After feeding each input character-level bounding box $b_{tmp} \in B_{tmp}$ and character category $c_{tmp} \in C_{tmp}$, the CGR module uses the glyph information corresponding to the category to generate positive point prompts P_{pos} and negative point prompts P_{nea} . Finally, the input image and the fine-grained prompts including P_{char}, P_{pos} and P_{neq} are fed together into SAM to generate accurate segmentation annotations.

B. Character Bounding-box Refinement Module

Scene text detection datasets [22], [23], [29]–[31] usually provide word-level bounding boxes and transcriptions. However, preliminary results in Figure 1 show that word-level prompts are insufficient for SAM to achieve accurate segmentation. Therefore, the **CBR** module is proposed to refine word-level annotations to character-level.

Specifically, we firstly use the character-awareness text detector CRAFT [32] trained on SynthText [33] dataset for preliminary detection. However, due to the domain gap between synthetic and real-world images, some adjacent character boxes cannot be completely separated, as exemplified by "Movie" in Figure 2(b). This will fail to uniquely assign a character category to a bounding box, and the glyph information corresponding to the character category cannot be used. To address this issue, we further determine whether the current character bounding box is detached based on the number of characters in the input transcription t_i . Subsequently, we use the bounding boxes to crop the input image and feed the cropped regions into the text recognizer to establish a one-to-one correspondence between character-level boxes and character categories. For sequences length greater than one character, such as the "vi" of "movie" in Figure 2(b), we feed the bounding box and the image into SAM and use the watershed algorithm to partition the logical map of the corresponding area of the bounding box into finer segments. Finally, the character-level bounding box is calculated through the connected domain, and an elaborated bipartite matching between character boxes and categories is implemented.

C. Character Glyph Refinement Module

Through the **CBR** module, we obtain both the bounding box and category for each character, whereas the mask obtained by feeding the character-level box as a prompt into SAM still has problems such as over-segmentation and under-segmentation illustrated as Figure 1. We observe that the English character, regardless of font or text direction, follows the fixed glyph structure determined by its category. Therefore, by utilizing known text categories across various English fonts, we can generate corresponding glyph templates and refine segmentation results using glyph information.

In detail, based on the collected text fonts, we can generate glyph templates for character categories with the ImageDraw and ImageFont library functions. We then categorize the pixels of these glyph templates into foreground and hole pixels. Each glyph template casts votes for each category, with pixels receiving votes based on their frequency. It is worth noting that only pixels with a vote rate exceeding a threshold are retained. Hole pixels become false point prompts P_{neg} , while the foreground pixels become positive point prompts P_{seg} . Finally, these visual prompts are fed into SAM to produce the final refined mask.

Baseline #1	-	-	78.30 81.85	83.52 87.81
#2 (TN=40) #3 (TN=80)	\checkmark	\checkmark	84.75 84.80	92.01 92.15

III. EXPERIMENTS

A. Datasets

TextSeg consists of 4024 high-quality images of scene and artistic text, with annotations including word-level and character-level bounding boxes and character-level masks.

COCO_TS contains 14690 low-quality pixel-level annotations for images in COCO-Text dataset. The annotations are obtained from the available bounding-boxes of the COCO-Text dataset exploiting a weakly supervised algorithm.

MLT_S contains 6896 low-quality pixel-level annotations of MLT images. Similarly, the annotations are obtained by a semi-supervised algorithm using bounding boxes.

B. Implementation Details

We choose SAM-B as our baseline, with the lightweight ViT-B [34] as the image encoder. The threshold in the CGR module is set to 0.6 by default. The number of text font files collected is 80. We conduct ablation experiments on the TextSeg dataset.

C. Comparison with SOTA Approaches

To demonstrate the accuracy of our method on scene text segmentation, we compare the performance of Char-SAM with other supervised scene text segmentation SOTA models on TextSeg as shown in Table I. While maintaining single-scale input resolution, Char-SAM still has competitive performances compared to supervised models with the multi-scale evaluation strategy. For the F-score, it is only about 1% behind the SOTA model TFT [14]. It proves our pipeline is solid on automatic annotation in scene text segmentation.

D. Ablation Study

1) Key modules: To evaluate the effectiveness of **CBR** and **CGR**, we conduct ablation studies on these modules, as shown

Fig. 3. Comparison of annotation quality of different scene text segmentation datasets.

in Table II. According to the baseline and #1, the **CBR** module can increase fgIoU and F-score by more than 3%. Illustrated by #1 and #2, the **CGR** module provides more fine-grained prompts based on glyph information, improving fgIoU and F-score by about 3% and 4% respectively. We also prove that the more templates provided, the more fully the font information can be utilized according to #2 and #3.

2) Prompt granularity: We conduct ablation experiments on various prompt types to demonstrate that finer granularity leads to better segmentation performance. As shown in Table III, character-level boxes have significant performance improvement compared to word-level boxes. Moreover, using prompts with positive and negative points can bring further improvement.

3) Dataset quality: To demonstrate that the quality of the dataset generated by our framework is better than COCO_TS and MLT_S generated by semi-supervised methods. We use TextRNet+DeepLabV3+ [1] trained on TextSeg as the baseline. #1 represents adding a 1000 subset of COCO_TS and a 1000 subset of MLT_S to the baseline for training. #2 indicates replacing annotations of the subsets in #1 with annotations generated by Char-SAM. As shown in Table IV, training with low-quality annotations will significantly reduce model performance by 3.96% in fgIoU and 2.90% in F-score, while training with annotations obtained by Char-SAM has a higher performance by 0.65% in F-score compared with the baseline.

E. Visualizations

We apply our framework on COCO-Text [22] and MLT17 [23] datasets respectively. The comparison of the obtained pixel-level annotations with COCO_TS and MLT_S is shown in Figure 3. The visualization shows that the masks obtained

by our method are more complete and smoother, with fewer misclassifications of foreground and background pixels.

IV. CONCLUSION

In order to settle the problem of the expensive annotation cost of the scene text segmentation dataset, we propose a framework that can refine word-level annotations into pixellevel annotations. At the same time, considering various issues of SAM on scene text, we proposed **CBR** and **CGR** modules to obtain character-level visual prompts. Experiments show that the quality of annotations generated by our Char-SAM is much better than that of semi-supervised methods.
