{anant_mehta, mcarthur, nkolloju, tzz}@tamu.edu

Abstract

The rapid progress in deep generative models has led to the creation of incredibly realistic synthetic images that are becoming increasingly difficult to distinguish from real-world data. The widespread use of Variational Models, Diffusion Models, and Generative Adversarial Networks has made it easier to generate convincing fake images and videos, which poses significant challenges for detecting and mitigating the spread of misinformation. As a result, developing effective methods for detecting AI-generated fakes has become a pressing concern. In our research, we propose HFMF, a comprehensive two-stage deepfake detection framework that leverages both hierarchical cross-modal feature fusion and multi-stream feature extraction to enhance detection performance against imagery produced by state-of-the-art generative AI models. The first component of our approach integrates vision Transformers and convolutional nets through a hierarchical feature fusion mechanism. The second component of our framework combines object-level information and a fine-tuned convolutional net model. We then fuse the outputs from both components via an ensemble deep neural net, enabling robust classification performances. We demonstrate that our architecture achieves superior performance across diverse dataset benchmarks while maintaining calibration and interoperability. The code is available at <https://github.com/taco-group/HFMF>.

1. Introduction

The rapid advancement of deep generative models has led to the creation of highly realistic and convincing fake digital media, including applications like image generation [1, 2], generative editing [3, 4], video generation [5, 6], audio recordings [7–9], and text generation [10]. These manipulated media, commonly known as deepfakes, have the potential to deceive, defame, and destabilize individuals, communities, and societies. The proliferation of deepfakes has become a pressing concern, as they can be used to spread misinformation, propaganda, and disinformation,

posing a significant threat to the foundation of trust in the digital age and modern-day life.

Despite the growing awareness of the deepfake problem, detecting and mitigating their spread remains a challenging task. Existing deepfake detection techniques often rely on finding specific trends or artifacts produced by generative models, but proficient attackers may easily bypass these methods [11]. Furthermore, the rapid growth of generative models has sparked a competition between deepfake detectors and deepfake producers, making it harder and harder to create efficient detection approaches [11].

Recent studies have highlighted the limitations of existing deepfake detection approaches, which often suffer from a generalization gap, failing to detect new, unseen deepfake attacks. Furthermore, the increasing computational complexity of deep learning-based detection models has raised concerns about their deployability in real-world applications, particularly on mobile devices with limited computational resources [12]. In this context, there is a significant need for a novel, efficient, and robust deepfake detection framework that can bridge the gap between current approaches and the rapidly evolving landscape of deepfakes.

To address this challenge, we propose a novel deepfake detection framework, which we dub HFMF, that combines hierarchical cross-modal feature fusion and multi-stream feature extraction (See Fig. 1). The first component of our approach leverages Vision Transformers (ViTs) [13–15] and Convolutional Neural Networks (ConvNets) [16, 17] in a hierarchical feature fusion mechanism to effectively capture both **local artifacts** and **global inconsistencies** introduced by deepfake manipulations. The second component integrates edge features, object-level context, and general image-based features extracted using a couple of lightweight expert models, including Sobel edge detection, YOLOv8 [18] object detection, and a fine-tuned Xception [19] model. The outputs from these components are fused through an ensemble deep neural network, enabling robust and accurate classification. Another key aspect of our architecture is its low number of trainable parameters, which is achieved by using various pre-trained models in both modules. Our results demonstrate that increased com-

plexity does not necessarily lead to better performance, and our model achieves competitive accuracy while maintaining high computational efficiency.

2. Related Work

2.1. Visual Generative Models

Visual generative models, including Generative Adversarial Network (GANs), Variational Autoencoders (VAEs), and diffusion models, have made significant strides in image generation. Latent diffusion models, such as those introduced by Rombach *et al.* [2], generate high-resolution images by modeling complex data distributions in a latent space, enabling efficient synthesis of realistic images. Diffusion models have also evolved into highly effective tools for generating diverse media; for example, Ho *et al.* [20] presented video diffusion models, which extend image diffusion models to temporal data. In the context of personalized generation, Guo *et al.* [5] introduced Animatediff, enabling animation with text-to-image diffusion models without extensive tuning. More specialized models, such as Audiogen [8], target audio generation, leveraging similar principles, while 4k4dgen [6] focuses on panoramic 4D generation at ultra-high resolutions. These advancements have enhanced synthetic content’s diversity and resolution, revolutionizing static and dynamic image generation tasks.

Moreover, powerful pre-trained visual generative models like Stable Diffusion [7] have facilitated strong generative editing methods that can easily manipulate or edit copyrighted or personal images to spread fake news [3, 21–24]. Without granting permission from the original publishers, these unauthorized edits, if leveraged by malicious hackers, can cause severe ethical or privacy outcomes [25]. Since these generative methods are highly robust, there is a pressing need for effective techniques to detect deepfakes.

2.2. Deepfake Detection Techniques

One issue in current deepfake detection models exposed by Cavia *et al.* is inherent biases in the commonly used datasets. Previous datasets used are produced by a single SOTA generative model and also include the same file format, resolution, compression encoding, and a few known simulated post-processing augmentations. It was shown that the models in part learn these hidden biases and do not generalize well to images found in the wild. To resolve this, Cavia *et al.* released the WildRF [26] dataset which contains images found in the wild on three social media platforms: Reddit, X (formerly Twitter), and Facebook.

Recent advancements in deepfake detection have primarily focused on addressing generative models like VAEs and GANs. For example, Lanzani *et al.* [27] proposed a lightweight Binary Neural Network (BNN) approach that augments RGB images with FFT and LBP features, achiev-

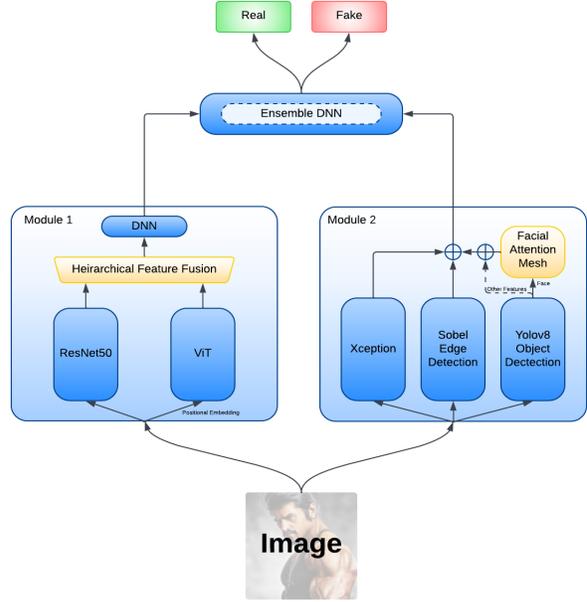

Figure 1. Our proposed dual stage ensemble network HFMF.

ing real-time detection with minimal accuracy loss and efficient memory usage. Similarly, Coccomini *et al.* [28] introduced Transformer-based architectures combining EfficientNet and cross-attention mechanisms, which outperformed traditional networks with lower computational demands. Other techniques, such as Zhao *et al.*’s [29] multi-attentional network with attention-guided augmentation and Bonettini *et al.*’s [30] siamese training with EfficientNetB4, demonstrated state-of-the-art results on popular datasets, although they often relied heavily on dataset-specific training.

As diffusion models become more prominent in generating highly realistic deepfakes, detection methods face increasing challenges. Techniques like Animollah *et al.*’s [31] graph-based framework and vision Transformers have shown promising results with high accuracy across diverse datasets. Additionally, Shiohara *et al.* [32] developed a method using Self-Blended Images (SBI) and EfficientNet for detecting statistical inconsistencies, achieving competitive cross-dataset performance. However, existing works often struggle to generalize across datasets and adapt to rapidly evolving generative technologies, leaving a critical bottleneck in handling deepfakes created with the latest diffusion-based models.

We will fuse together several key components and ideas of these works to develop a novel ensemble for accurate deepfake detection.

3. Proposed Method

In this section, we present the proposed deepfake detection framework, HFMF, which consists of two comple-

mentary modules: a hierarchical cross-modal feature fusion mechanism and a multi-stream feature extraction pipeline. To enhance the reliability of the first module, we apply a calibration technique to address the known issue of miscalibration in deep ResNets, ensuring that uncertainty does not compromise detection performance. Simultaneously, we have designed the second module to be explainable, enabling the interpretability of the model’s predictions. Additionally, we generate explainability maps at the end of this module to provide insights into the regions of the input image that contributed most to the final classification, further validating the robustness and transparency of the proposed framework. Figure 1 shows the final model.

3.1. Module 1: Hierarchical Feature Fusion

Semantics-aware feature extraction Given an input image $X \in \mathbb{R}^{H \times W \times 3}$, the ViT model, specifically ViT_{Base-16} [13], pre-trained on ImageNet [33], partitions X into N patches of size $p \times p \times 3$. Each patch is linearly embedded to form a 768-dimensional feature vector, yielding:

$$E_{ViT} = ViT_{\text{fine-tuned}}(X), \quad E_{ViT} = [e_1, e_2, \dots, e_N] \quad (1)$$

where $e_i \in \mathbb{R}^{768}$. Enjoying the global awareness of the attention mechanisms, the ViT extracted features to capture the contextual or semantic information of the input image, which will be leveraged to fuse with other feature representations.

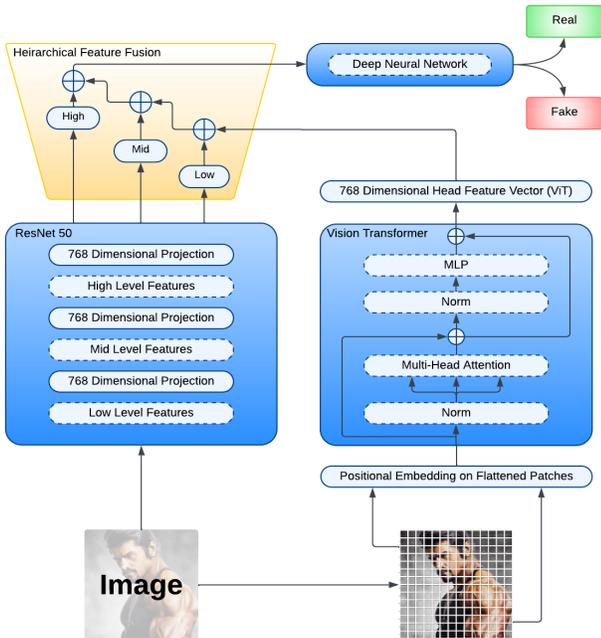

Figure 2. Module 1: Hierarchical Cross Feature Fusion.

Multi-scale feature extraction DeepFake imagery often exhibits abnormalities in local regions, e.g., the famous “finger issues” in many diffusion models [34]. Thus, to account for these local artifacts, we employ the pre-trained ResNet to extract intermediate feature representations from multiple stages, each capturing a different abstraction level:

$$F_1, F_2, F_3 = ResNet(X), \quad (2)$$

Here, F_1, F_2, F_3 represent feature maps at different spatial resolutions, respectively, with F_1 capturing low-level features and F_3 capturing relatively higher-level features. As DeepFake-type distortions may exhibit at a different scale, according to the generative capabilities of the models, we exploit all the ConvNet features to conduct the final detection.

Hierarchical Attention-based Fusion We combine the global contextual features from the ViT branch and the local hierarchical features from the ResNet branch using a hierarchical dot-product similarity mechanism. More specifically, for each feature map F_i , we first reshape it to be in the same resolution ($\mathbb{R}^{(H \cdot W) \times 768}$). Then we compute the dot-product similarity using an attention model:

$$S_{lvi} = \frac{QK^\top}{\sqrt{d_k}}, \quad d_k = 768, \quad (3)$$

where initially $Q = E_{ViT} \in \mathbb{R}^{N \times 768}$, $K = V = F_i \in \mathbb{R}^{(H \cdot W) \times 768}$, and $S_{lvi} \in \mathbb{R}^{N \times (H \cdot W)}$. The hierarchical dot-product similarity operation (HDS) is performed as follows:

$$HDS(Q, K) = \text{softmax}(S_{lvi})V, \quad (4)$$

$$Z_{\text{low}} = HDS(E_{ViT}, F_{\text{low}}) \in \mathbb{R}^{N \times 768}, \quad (5)$$

$$Z_{\text{mid}} = HDS(Z_{\text{low}}, F_{\text{mid}}) \in \mathbb{R}^{N \times 768}, \quad (6)$$

$$Z_{\text{high}} = HDS(Z_{\text{mid}}, F_{\text{high}}) \in \mathbb{R}^{N \times 768}. \quad (7)$$

The final representation, $V_{\text{final}} = Z_{\text{high}}$, integrates multi-scale information fused incrementally with the global context-aware features, capturing a strong representation power by using two types of neural nets. The fused vector $V_{\text{final}} \in \mathbb{R}^{N \times 768}$ serves as the input to the deep neural network for further processing and obtaining raw logits. Figure 2 depicts this module.

Uncertainty Calibration In deep learning models, predicted probabilities often suffer from miscalibration, where the model’s confidence does not reflect the true likelihood of correctness. To address this, we apply *Platt Scaling* [35], which adjusts the probability estimates using a logistic regression model on the raw logits z from the network. The calibrated probability \hat{p} is given by:

$$\hat{p} = \frac{1}{1 + \exp -(Az + B)}, \quad (8)$$

where A and B are learned parameters that minimize the negative log-likelihood. We use expected calibration error (ECE) to measure miscalibration. Calibration is crucial after the hierarchical fusion in Module 1, as deep residual networks often produce overconfident predictions [35].

$$\text{ECE} = \frac{1}{N} \sum_{i=1}^N \frac{|B_i|}{N} |\text{acc}(B_i) - \text{conf}(B_i)|, \quad (9)$$

where:

- $|B_i|$ is the number of samples in the i -th bin,
- N is the total number of samples,
- $\text{acc}(B_i)$ is the accuracy in the i -th bin,
- $\text{conf}(B_i)$ is the average confidence in the i -th bin.

3.2. Module 2: Multi-Stream Local-Feature Extraction

DeepFake media also shows artifacts on small, localized regions, including edges, faces, and small objects, to name a few [36]. Here, we propose a three-branched framework as described in figure 3, to capture a variety of localized features using lightweight specialized expert models.

Object and Facial Region Extraction We employ the YOLOv8 [18] to process the full image X . If a face is detected, cropped regions X_f are extracted and layered with a Facial Attention Mesh using MediaPipe [37] to capture facial features like the mouth and eyes. These features are concatenated with object features X_{objects} , forming the final representation:

$$F_X^{\text{YOLO}} = X_f + X_{\text{objects}}.$$

X_{objects} refers to rest of the features from the image, excluding the face. This module not only emphasizes facial features but also addresses background perturbations to improve robustness in feature representation.

Texture Artifact Embedding The Sobel filter [38] operates on X to compute gradients in horizontal (G_x) and vertical (G_y) directions:

$$G = \sqrt{G_x^2 + G_y^2}.$$

These gradients enhance edge detection, producing edge-enhanced images X_s , which emphasize subtle texture-based manipulation artifacts. The features extracted here, F_X^{Sobel} , are passed to the final decision-making layer to ensure texture-related cues are captured.

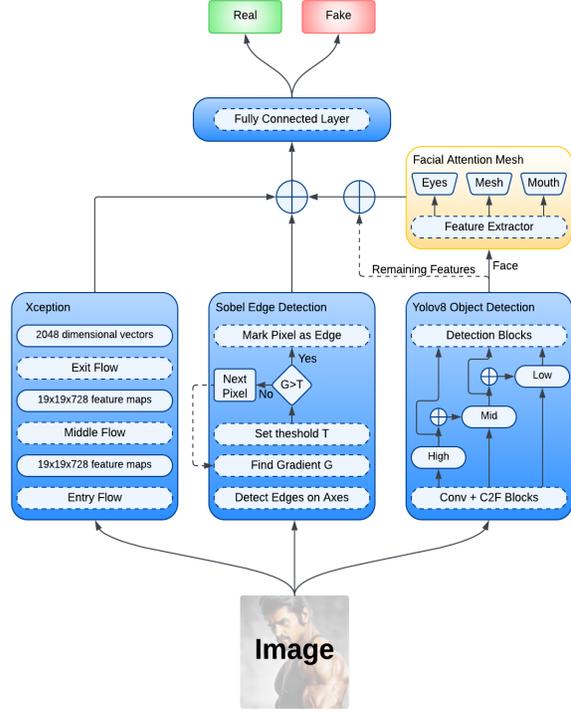

Figure 3. Module 2: Multi-Stream Local Feature Extraction.

Fine-Grained Feature Extraction We utilize the XceptionNet [19], pre-trained on the ImageNet dataset, processes X to extract embeddings $F_X^{\text{Xception}} \in \mathbb{R}^{d_x}$. These embeddings encode fine-grained manipulation patterns and global contextual cues. The module ensures that even nuanced facial alterations or deepfake features are effectively learned.

3.2.1 Integration Across Modules

The outputs from all three modules— F_X^{YOLO} , F_X^{Sobel} , and F_X^{Xception} —are concatenated and fed into a fully connected layer for final classification:

$$F_X = F_X^{\text{YOLO}} \oplus F_X^{\text{Sobel}} \oplus F_X^{\text{Xception}},$$

where \oplus denotes the concatenation operation. This integration ensures a comprehensive feature representation, capturing spatial, texture, and contextual features for distinguishing real versus fake inputs.

3.3. Ensemble Decision Making

HFMF, our ensemble model, depicted in Fig. 1, integrates predictions from two specialized modules to enhance overall performance and robustness, using logits of the final neural networks in both cases. Module one combines global features from Vision Transformer (ViT) and local features from ResNet50 through a hierarchical dot-product

similarity mechanism. The resulting multi-scale representation V_{final} is calibrated using Platt Scaling to correct overconfident predictions, producing reliable logits for a prediction. Module two extracts multi-stream features using YOLOv8 for facial regions, Sobel filtering for texture artifacts, and XceptionNet for fine-grained manipulation patterns. The fused feature vector F_X from Module two is processed through a neural network to generate logits. The respective output logits from these modules are fused through a weighted aggregation mechanism using a deep neural network, leveraging complementary strengths of different feature representations.

This ensemble strategy ensures improved accuracy and interpretability, as each module contributes domain-specific insights while mitigating individual weaknesses.

4. Experiments

4.1. Experimental Setup

We utilized NVIDIA RTX 6000 GPU nodes for training and evaluation of our three models, Module 1, Module 2 and the final HFMF ensemble. We trained final ensemble with early stopping to prevent overfitting. This setup was optimized to balance computational efficiency and model performance. Additionally, we employed a two-stream architecture, where Module One and Module Two were trained separately before ensembling.

4.2. Datasets and Benchmarks

One key to a strong deepfake detection model is training with data from state-of-the-art Generative AI models. Even the best architecture cannot compensate for outdated training data in identifying realistic, high-quality fakes.

For this reason, we use WildRF dataset released by Cavia *et al.* [26] as our primary benchmark. The WildRF dataset is compiled of images, real and fake, found on social media websites Facebook (FB), Reddit (R), and X (formerly Twitter) in 2024 (the year our experiments were conducted). The AI generated images reflect the high quality of the most SOTA models available today including Open AI’s DALL-E 3 [42], Google DeepMind’s Imagen3 [1], X AI’s Grok-2 [43] and more, as well as finetuned versions of these generative models on specialized datasets, making it nearly imperceptible in some cases for the human eye to recognize the deepfakes. Furthermore, WildRF inherently eliminates several biases, such as JPEG compression, found in other generated image datasets. Also, this dataset includes images generated from unknown synthesizer models, making it more practical for real-world scenarios.

A main concern for deepfakes is identity and misinformation attacks with face generation and manipulation. To address this concern, the second benchmark we use is CollabDif [44]. CollabDif uses a recent multi-modal approach

fusing Latent Diffusion Models (LDMs) and Variational AutoEncoders (VAEs) for generating face images as proposed by Huang *et al.* in 2023. The model takes both textual prompts and facial segmentations for more control in generating and editing photo realistic images.

Together, the WildRF and CollabDiff datasets ensure comprehensive testing of our approach. WildRF covers both facial and non-facial manipulations, while CollabDiff focuses on high-quality facial deepfake generation and editing.

4.3. Main Results

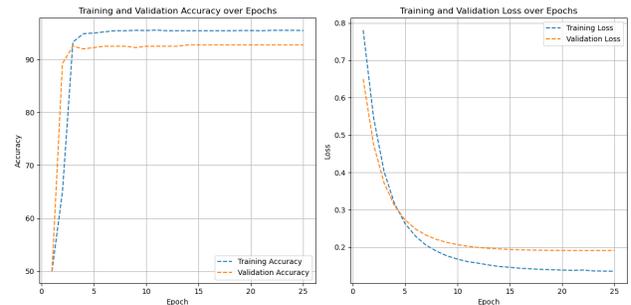

Figure 4. Training and Validation curve for HFMF (WildRF).

We conducted extensive experiments on the WildRF dataset, evaluating the model on three distinct test subsets: Facebook, Reddit, and Twitter, as well as the validation set. Additionally, we tested on the CollabDiff validation set, which is generated using latent diffusion models. Despite its small size, CollabDiff consistently yielded nearly perfect results, a trend corroborated by prior works in the literature.

Our experiments evaluated the performance of Module One, Module Two, and the final ensemble. In Module One, a Vision Transformer (ViT) architecture was utilized with a patch size of 16×16 , effectively capturing hierarchical visual features. Module Two employed a multi-stream model incorporating Sobel edge detection and XceptionNet, enhancing spatial and contextual feature fusion. These modules were independently trained before combining their outputs in the final ensemble.

For the final ensemble (HFMF), we set 100 epochs for both the datasets, employing early stopping. For example, in the case of WildRF the training halted after 25 epochs. The training process achieved a Train Accuracy of 95.43%, a Validation Loss of 0.1911, and a Validation Accuracy of 92.7%. Figure 4 illustrates the training and validation accuracy and loss curves for the HFMF architecture.

Table 1 presents the accuracy comparisons for various methods tested on the WildRF test subsets. Module One achieved accuracy rates of 86.6% on Facebook, 93.0% on Reddit, and 86.0% on Twitter, with a mean accuracy of

Method	Facebook	Reddit	Twitter	Mean	Validation
LaDeDa [26]	81.9%	91.8%	83.3%	85.7%	-
Tiny-LaDeDa [26]	80.7%	84.5%	82.3%	82.5%	-
CNNDet [39]	70.6%	75.4%	71.4%	72.5%	-
PatchFor [36]	77.1%	87.8%	81.6%	82.2%	-
CLIP [40]	78.4%	80.8%	78.1%	79.1%	-
NPR [41]	76.6%	89.8%	79.5%	81.9%	-
Module 1 (M1)	86.6%	93.0%	86.0%	88.5%	91.7%

HFMF (M1+M2)	86.9%	92.3%	85.8%	89.4%	92.7%

Table 1. Accuracy comparison of different methods. All methods are trained on the WildRF training set and evaluated on the three subsets of the WildRF test set. Our results show remarkable improvement across all test sets over previous methods.

Dataset	ECE (Uncalibrated)	ECE (Calibrated)	Percentage Decrease (↓)
WildRF (Train)	0.0580	0.0473	18.97%
WildRF (Val)	0.1017	0.0921	9.48%
WildRF (FB)	0.1549	0.1330	14.13%
WildRF (Reddit)	0.0830	0.0666	19.79%
WildRF (Twitter)	0.1668	0.1399	16.14%

Table 2. ECE on Datasets after Calibration of Module 1.

88.5% and a validation accuracy of 91.7%. Module Two achieved accuracy rates of 81.9% on Facebook, 90.9% on Reddit, and 85.4% on Twitter, with a mean accuracy of 86.0% and a validation accuracy of 88.4%. The final ensemble which we call HFMF further enhanced these results, achieving 86.9% on Facebook, 92.3% on Reddit, and 85.4% on Twitter, with a mean accuracy of 89.4% and a validation accuracy of 92.7%. Table 3 highlights the classifica-

Dataset	Acc.	Prec.	Rec.	F1
WildRF (FB) [26]	86.9%	0.92	0.81	0.86
WildRF (R) [26]	92.3%	0.95	0.91	0.93
WildRF (X) [26]	85.8%	0.97	0.81	0.88
CollabDif (VAL) [44]	100%	1.00	1.00	1.00

Table 3. Classification scores across different test sets using our final HFMF (M1+M2).

Method	CollabDif(VAL)
Module 1 (M1)	100%
Module 2 (M2)	99.50%
HFMF (M1+M2)	100%

Table 4. Proposed methods’ results on CollabDif.

tion metrics, including accuracy (Acc.), precision (Prec.), recall (Rec.), and F1 scores, across different test subsets. On the CollabDif validation set, as shown in Table 4, Module One and the final ensemble achieved 100% accuracy, while Module two closely followed at 99.50%. These results emphasize the effectiveness of hierarchical fusion and multi-stream modeling in HFMF in delivering robust and accurate deepfake detection. In the following sections, we also discuss the ablation study results.

4.4. Calibration Results

For calibrating Module 1 on the datasets, we utilized 500 bins for probability calibration. This approach was driven due to the highly skewed distribution of predicted probabilities, which tended to concentrate around the extreme values close to 0 or 1. Using a large number of bins allowed for finer granularity in capturing and adjusting these probability estimates, thereby improving the model’s calibration and ensuring that the predicted probabilities better aligned with the observed outcomes. This approach was particularly critical given the dataset’s characteristics and the need for precise probability estimates in downstream tasks. After calibration on the training dataset, the Expected Calibration Error (ECE) was significantly reduced, demonstrating the effectiveness of the calibration method. The uncalibrated and calibrated ECE values for various datasets (training, validation, and social media subsets) are provided below in table

Method	ViT-B/16	ResNet50	Facebook	Reddit	Twitter	Mean
Pre-trained ViT-B/16	✓	×	78.1%	89.4%	85.0%	84.1%
Pre-trained ResNet50	×	✓	84.4%	94.6%	84.0%	87.7%
Module 1 (ViT-B/16+ResNet50)	✓	✓	86.6%	93.0%	86.0%	88.5%
HFMF (Module 1+Module 2)	✓	✓	86.9%	92.3%	85.8%	89.4%

Table 5. Ablation studies for Module 1 (ViT-B/16: Vision Transformer, ResNet50) on WildRF.

Method	XCN	Yolo	SOBEL	Facebook	Reddit	Twitter	Mean
Pre-trained XCN + SOBEL	✓	×	✓	88.2%	89.4%	78.2%	85.3%
Yolo + SOBEL	×	✓	✓	66.9%	76.8%	70.6%	71.4%
Pre-trained XCN + Yolo	✓	✓	×	80.9%	91.6%	84.2%	85.6%
Module 2 (Yolo+XCN+SOBEL)	✓	✓	✓	81.9%	90.9%	85.4%	86.0%
HFMF (Module 1+Module 2)	✓	✓	✓	86.9%	92.3%	85.8%	89.4%

Table 6. Ablation studies for Module 2 (XCN: XceptionNet, Yolo: Yolov8, SOBEL: Sobel Edge Detection) on WildRF.

2. Relative change or the decrease in ECE is also analyzed.

The table above shows the ECE values for both uncalibrated and calibrated models across various datasets. As seen, calibration significantly reduces the ECE, with the largest decrease observed on the Reddit test dataset (19.79%) and the smallest on the validation set (9.48%). These improvements demonstrate the effectiveness of calibration in enhancing model performance, especially when evaluated on real-world data from platforms like Facebook, Reddit, and Twitter present in WildRF dataset.

In the case of the CollabDif dataset, the model’s initial calibration yielded an ECE almost 0, indicating perfect calibration, i.e. model’s predictions were already well-aligned with true probabilities, and further calibration was unnecessary.

4.5. Grad-CAM for Feature Visualization

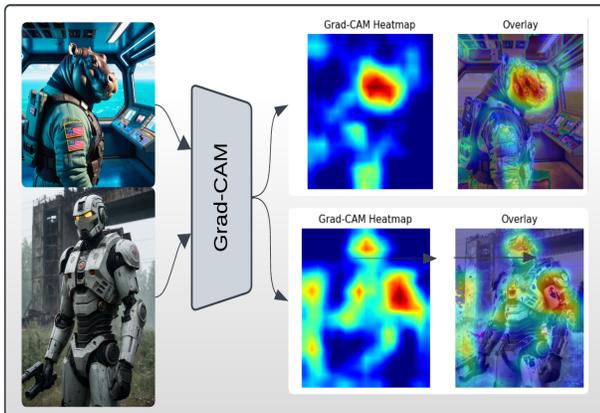

Figure 5. Grad-CAM visualization for WildRF

To explain feature extraction in Module 2, we employ Grad-CAM (Gradient-weighted Class Activation Mapping) [45], which generates a localization map $L_c^{\text{Grad-CAM}} \in \mathbb{R}^{u \times v}$ highlighting regions in the input image X relevant to the model’s decision. For a target class c , Grad-CAM computes the gradients of the class score y_c (pre-softmax) with respect to feature map activations A_k , and combines them using importance weights α_k^c :

$$L_c^{\text{Grad-CAM}} = \text{ReLU} \left(\sum_k \alpha_k^c A_k \right),$$

where ReLU suppresses irrelevant regions. Grad-CAM enhances interpretability by visualizing class-relevant features, as shown in Fig. 5 and Fig. 6. These heatmaps illustrate the rationale behind why Module 2 classified the images in the respective categories.

4.6. Ablation Studies

As shown in Table 5, Module 1 (M1), which combines Vision Transformer (ViT-B/16) and ResNet50, achieves a mean accuracy of 88.5%, surpassing standalone ViT-B/16 (84.1%) and ResNet50 (87.7%). This demonstrates the benefit of leveraging complementary features from both architectures using proposed hierarchical cross feature fusion.

Similarly, Module 2 (M2) as depicted in Table 6, which integrates Yolov8, Sobel edge detection, and XceptionNet, achieves a mean accuracy of 86.0%, outperforming simpler combinations among these models. Notably, the addition of XceptionNet in M2 significantly enhances performance by providing robust feature extraction capabilities, complementing the edge detection of Sobel and the object localization of Yolov8. This synergy highlights the importance of

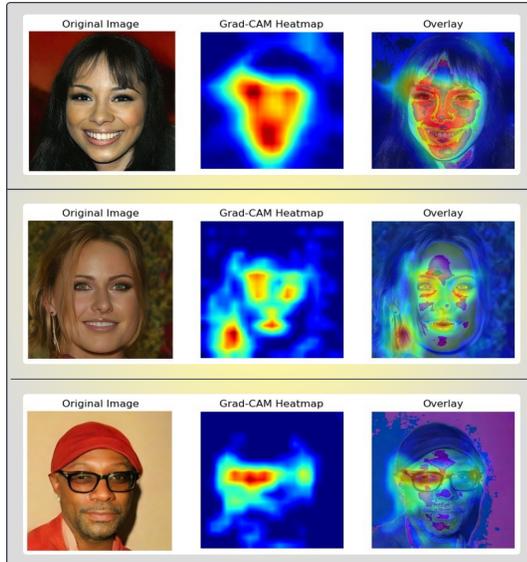

Figure 6. Grad-CAM visualization for CollabDif

combining diverse model functionalities to achieve superior results across datasets. The inclusion of all three components in M2 allows it to leverage edge detection and object localization alongside deep feature extraction, resulting in more robust performance across datasets.

However, neither M1 nor M2 alone could consistently achieve top performance across all datasets. While M2 performs slightly lower than M1 in terms of mean accuracy (86.0% vs. 88.5%), it adds valuable explainability through its integration of Sobel edge detection and object localization, which enhances interpretability. By fusing M1 and M2 in HFMF, the model achieves a mean accuracy of 89.4%, successfully combining the strengths of both modules. This fusion allows HFMF to deliver superior results while maintaining both certainty and explainability.

5. Conclusion & Future Scope

In this work, we present a robust multi-module dual stream approach for deepfake detection, combining state-of-the-art techniques in feature extraction, hierarchical fusion, and ensemble decision-making. By leveraging calibrated outputs, Grad-CAM explainability, and a combination of modern architectures such as YOLOv8, Sobel filtering, and XceptionNet, our model demonstrates improved reliability and accuracy. The integration of training data from recent Generative AI models ensures adaptability to real-world scenarios. This comprehensive pipeline not only enhances detection performance but also provides interpretability, making it a step forward in addressing the challenges posed by realistic deepfakes.

In future work, this framework can be extended to mul-

timedia forensics by incorporating multi-modal inputs like video, audio, and textual metadata, enabling detection beyond images. The hierarchical fusion mechanism can also address disinformation and credibility assessment in real-world scenarios, such as social media and forensic investigations. We will also focus on improving robustness and real-time efficiency in constrained environments.

Our fully supervised approach will be extended to semi-supervised or unsupervised settings, broadening applicability to real-world scenarios with unseen synthesizers.

Ethical Statement: This work aims to address the ethical challenges posed by deepfakes, focusing on combating their misuse for misinformation, fraud, and privacy violations. Our detection framework is intended for responsible applications that promote transparency and safety. We encourage its ethical use and advocate for continued collaboration to mitigate the broader societal impacts of generative AI.
