Abstract. This study focuses on analysing the coverage of publications' metadata available in the Current Research Information System (CRIS) infrastructure of the University of Bologna (UNIBO), implemented by the IRIS platform, within an authoritative source of open research information, i.e. OpenCitations. The analysis considers data regarding the publication entities alongside the citation links. We precisely quantify the proportion of UNIBO IRIS publications included in OpenCitations, examine their types, and evaluate the number of citations in OpenCitations that involve IRIS publications. Our methodology filters and transforms data dumps of IRIS and OpenCitations, creating novel datasets used for the analysis. Our findings reveal that only 37.7% of IRIS is covered in OpenCitations, with journal articles exhibiting the highest coverage. We identified 4,290,096 citation links pointing to UNIBO IRIS publications. From a purely quantitative perspective, comparing our results with broader proprietary services like Scopus and Web of Science reveals a small gap in the average number of citations per bibliographic resource. However, further analysis with updated data is required to support this speculation.

Keywords: Scientometrics, informetrics, Bibliographic metadata, OpenCitations, IRIS, CRIS systems, Open research information

Introduction

The importance of having available *research information*, i.e. metadata that enables one to understand how research is conducted and communicated, is central to several activities that involve research-performing institutions and funding organisations, which includes strategic

prioritisation, policy decisions, and research outcomes. Recently, there has been a lot of pressure, usually from the academic community and advocates for Open Science practices, to convince the producer of such information to release it as open material to maximise its reuse and, thus, foster transparency for the activities mentioned above. Indeed, in the past few years, we have seen great attention to this respect in official international reports, such as the Recommendation on Open Science by UNESCO (2021), and several initiatives born from scholars such as the Initiative for Open Citations (I4OC, https://i4oa.org), and CoARA (Coalition for Advancing Research Assessment, 2022).

These attempts have either framed the problem of the availability of the research information into a bigger picture, as by UNESCO (for Open Science) and CoARA (for research assessment), or focussed the discussion on specific types of research information, as in I4OC (for open citations) and in I4OA (for open abstracts). However, in 2024, the Barcelona Declaration on Open Research Information (DORI, <u>https://barcelona-declaration.org</u>) put research information as the main focus of its activities. Created with the effort of several parties coming from and/or working with academia and already advocated in the production and publication of open research information, the Barcelona Declaration aimed to gather supporters for a critical agenda organised into four main commitments:

- *openness* that should be the default for the research information used and produced by research-performing organisations and funders;
- *collaboration* pushing for working with services and systems that support and enable (i.e. by producing and publishing) open research information;
- *sustainability* by supporting, e.g. financially and taking part in their governance, open infrastructures dedicated to the production and publishing of open research information;
- *transition* taking part in collective actions to accelerate the transition to openness of research information.

An initial agenda of the priorities co-created by the Declaration's signatories and supporters has been published as one of the outcomes of the Paris Conference on Open Research Information, held in September 2024. The agenda is derived from the conference report (Barcelona Declaration on Open Research Information, 2024), where the primary and most voted action item was dedicated to replacing closed systems (e.g. Web of Science and Scopus) with open alternatives. Of course, other actions have been highlighted as very important as well, as they are crucial prerequisites for implementing such a replacement, in particular the evaluation of such existing open data sources on their quality, coverage (in terms of both kinds of research outcomes represented and additional contextual information such as fundings and grants), and openness/transparency aspects.

It is up to the Declaration's signatories to collaborate with providers of open research information to understand the current status of the potential adoption of such open sources in signatories' institutional practices. To reach that level of acknowledgement, preliminary studies and experiments must be set up and run within the involved institutions to share common practices, current statuses, and possible directions to follow to enable broad and systematic adoption of such open research information. Within this scenario, the University of Bologna, one

of the initial signatories of the Declaration, is working to devise possible paths to comply with all the Declaration's commitments.

The work presented in this paper introduces part of the effort at the University of Bologna to analyse fundamental dimensions related to such commitments, focusing on understanding the requirements necessary to meet, in principle, the commitment *transition* of the Declaration. In particular, the research questions (RQs) we address in this work are the following ones:

- 1. What is the current coverage (in terms of number and publication type) of the publications authored by a scholar affiliated with the University of Bologna (UNIBO publications from now on) in an existing and well-recognised source of open research information?
- 2. According to the open source considered, how many citation links involve UNIBO publications (either as citing entity, cited entity, or both)?

To answer these questions and make the whole analysis transparent and reproducible, many requirements, complying with the Declaration's commitments, had to be met. First, we needed access to all bibliographic metadata of UNIBO publications available under open licenses and published using open and machine-readable formats (commitment *openness*). That has been addressed thanks to the collaboration of two units of the University of Bologna, dedicated to IT Systems and Services (CeSIA) and Planning and Communication (APPC), which enabled us to produce a CSV dataset with all the UNIBO publications (as of 14 March 2024) to use for the analysis.

Second, we needed to work with one of the authoritative sources of open research information containing bibliographic metadata and citation data to measure the data coverage highlighted in RQ1 and RQ2 (commitment *collaboration*). We chose to interact with OpenCitations (<u>https://opencitations.net</u>) (Peroni & Shotton, 2020), which is an independent not-for-profit infrastructure organisation dedicated to the publication of open bibliographic and citation data that is managed, for administrative purposes, by the Research Centre for Open Scholarly Metadata (<u>https://openscholarlymetadata.org</u>) of the University of Bologna (commitment *sustainability*).

Given these premises, the results obtained from our analysis sketch out an initial picture of the current status of alignment with open research information providers and set up possible paths for further studies and experimentation. In addition, as a direct consequence of the study, it has initiated a practice of publishing yearly dumps of bibliographic information of all UNIBO publications into the University institutional repository for research data (AMSActa, https://amsacta.unibo.it).

The rest of the paper is organised as follows: In Section "Materials and Methods", we introduce all the data, protocols, and methodology developed for running the analysis. In Section "Results", we present the outcomes of our analysis, which are then largely discussed in Section "Discussion." Finally, Section "Conclusions" concludes the paper and sketches future works.

Materials and methods

This section introduces all the data and protocols adopted for the analysis. All the material produced is available at https://github.com/open-sci/2023-2024/blob/main/docs/Atreides/material.md. In particular, the Data Management Plan (Zilli et al., 2024a), the description of the protocol to gather and analyse the data (Zilli et al., 2024b), the software implementing the protocol (Zilli et al., 2024f), and the final data obtained by running the protocol implementation (Zilli et al., 2024c, 2024d, 2024e) are all available online to enable the reproducibility of the study.

Data reused

The analysis proposed in this paper reuses data included in two different sources: one institutional source, the Institutional Research Information System (IRIS) used by the University of Bologna, which contains metadata about UNIBO publications, and an open science infrastructure providing bibliographic metadata and citation data, i.e. OpenCitations, having a broader scope in coverage worldwide.

IRIS

The IRIS software system (Bollini et al., 2016) has been developed by CINECA, a not-for-profit Consortium comprising 70 Italian universities, 4 Italian Research Institutions, and the Italian Ministry of Education. This software is adopted by most Italian universities to handle their current research information system (CRIS). IRIS enables universities to collect and organise the bibliographic metadata of all the institutions' scientific production, allows the scholars' direct involvement in providing information about their products, and uses a generic data model shared by all IRIS installations – one for each institution involved.

IRIS is used by the University of Bologna, which organised yearly campaigns (having the deadline set to the end of February) to update the status of the related database of research products massively – even if every scholar can update its publications information when preferred during the year. The information contained in IRIS concerns basic bibliographic metadata about scientific products (title, author list, publication year, publication venue, persistent identifiers, etc.) but also contains metadata bound to specific licenses and agreements with the publishers (e.g. the abstract of the scholarly articles) and personal data (e.g. the name of the people who have worked on the curation of such metadata) that cannot be shared with licenses enabling to maximise their reuse such as Creative Commons Zero (CC0, https://creativecommons.org/publicdomain/zero/1.0/).

To this end, we have worked on a dump of the University of Bologna's IRIS data downloaded on 14 March 2024, i.e. immediately after the last massive update at the University, to extract only the relevant metadata we could publish safely using CC0 as a license. The dataset produced and used in this work (Amurri et al., 2024) is hosted in the AMSActa Institutional Research Repository. It comprises bibliographic metadata of all UNIBO publications (research articles, books, databases, etc.) available in IRIS.

This dataset consists of seven distinct CSV files, each descriptive of a specific aspect of the publications, and contains 304,983 bibliographic entities for a total size of 267 MB. As summarised in Table 1, it includes details about the people involved, such as authors and editors, and publication identifiers like DOIs. Additionally, the dataset captures information on the language of the publications, basic bibliographic details like titles, publication dates, and types, along with publisher information. In addition, a README file accompanies the dataset, offering additional documentation and guidance.

As described in the documentation of the schema used for each column in the various files (available online in Italian at https://wiki.u-gov.it/confluence/display/public/UGOVHELP/ODS+-+IR-L1), not all the metadata attributes are mandatory. When information is not provided, the value in the CSV files is left blank.

Filename	Description
ODS_L1_IR_ITEM_CON_PERSON.csv	Information (internal ID, ORCID, name, etc.) about each individual (authors, editors, etc.) involved in the publications of the dataset
ODS_L1_IR_ITEM_DESCRIPTION.csv	List of authors and author count for each publication
ODS_L1_IR_ITEM_IDENTIFIER.csv	Identifiers of publications, such as DOIs, PMIDs, ISBNs and others
ODS_L1_IR_ITEM_LANGUAGE.csv	Language of the publication (if applicable)
ODS_L1_IR_ITEM_MASTER_ALL.csv	Basic metadata (title and publication date)
ODS_L1_IR_ITEM_PUBLISHER.csv	The names and locations of the publishers of the BRs
RELATION.csv	Additional metadata regarding the publication context (venue, editors, etc.)

Table 1. A description of the CSV files included in the IRIS dataset dump.

OpenCitations

OpenCitations (Peroni & Shotton, 2020) is a community-guided open infrastructure that provides access to global scholarly bibliographic and citation data. The infrastructure offers its data for bulk download and enables programmatic access via various interfaces, including REST APIs and Web GUI. OpenCitations uses Semantic Web technologies to model citations and

bibliographic metadata (Daquino et al., 2020), providing comprehensive, freely accessible data (under a CC0 license) while ensuring semantic interoperability.

OpenCitations manages and maintains two main collections, both relevant to the purposes of this work. The first collection is the OpenCitations Index (OC Index from now on) (Heibi et al., 2024), a unified repository of open citations aggregated from various sources – Crossref (Hendricks et al., 2020, DataCite (Brase, 2009), National Institute of Health - Open Citation Collection (Hutchins et al., 2019), OpenAIRE (Manghi et al., 2012), and the last source ingested, i.e. the metadata made available by the Japan Link Centre (Moretti et al., 2024). The second collection, OpenCitations Meta (OC Meta from now on) (Massari et al., 2024), comprises the bibliographic metadata of all citing and cited bibliographic resources included in the OpenCitations Index. Provenance data and change tracking information are also generated for both collections using a provenance model based on the PROV Ontology (Lebo et al., 2013), a W3C Recommendation. This approach ensures transparency and traceability by capturing detailed information about data creation/modification, actors involved, and primary sources.

The OC Meta dump used in this work was published in April 2024 by OpenCitations in CSV format on Figshare (OpenCitations, 2024). Each line in the CSV dump represents a bibliographic entity and its corresponding metadata. These metadata fields provide information such as the document's unique ID(s) (DOI, PMID, ISSN, OpenAlex ID, etc.), title, authors, publication date, and the venue to which the document has been published, if any. In addition, details about the journal issue and volume are tracked (if applicable), page ranges are recorded, and the type of resource, the publisher, and any editors involved. This structured metadata allows for a comprehensive basic description of each bibliographic entry.

All bibliographic entities in OC Meta are identified using an internal identifier called OMID (the OpenCitations Meta Identifier). The OMID structure is as follows:

[entity_type_abbreviation]/[supplier_prefix][sequential_number]

For example, *br/0601* is a valid OMID, where *br* stands for *bibliographic resource*, *060* is one of the supplier prefixes indicating the dataset (OpenCitations Meta), and *1* is the sequential number.

The dataset comprises 114,703,611 bibliographic entities, 298,847,794 authors, 2,465,711 editors, 711,711 publication venues, and 241,783 publishers. The compressed data totals 11 GB (46 GB when uncompressed) and is distributed across CSV 28,249 files. Table 2 shows an example of how an entity is represented in the OC Meta CSV dump.

Table 2. A sample taken from the OC Meta CSV dump; the first column represents the attributes
(columns in the CSV) of the corresponding bibliographic entity.

The OC Index dump used in this work was published by OpenCitations in CSV format on Figshare in December 2023 (OpenCitations, 2023). Each line in the CSV dump represents a citation, treated as a first-class data entity, each with its own specified metadata. Such metadata includes:

- 1. the identifier of the citation;
- 2. the citing entity;
- 3. the cited entity;
- 4. the citation creation date (corresponding to the publication date of the citing entity)
- 5. the time interval between the citing and cited publication dates;
- 6. a flag indicating whether it is an author self-citation (i.e. when the citing and cited entities share at least one author);
- 7. a flag indicating whether it is a journal self-citation (i.e. both citing and cited entities are published in the same journal).

Each citation is identified using an Open Citation Identifier, or OCI (Peroni & Shotton, 2019). The OCI structure of the citations in the OC Index is as follows:

oci:[citing_n_omid]-[cited_n_omid]

For example, *oci:06101801781-062501777134* is a valid OCI, where *06101801781* is the numeral part of the OMID of the citing bibliographic resource (i.e. *br/06101801781*), and *062501777134* is the numeral part of the OMID of the cited bibliographic resource (i.e. *br/062501777134*).

In Table 3, we show an example of how the citation *oci:06404659278-06201483429* and corresponding attributes are represented in the CSV dump. The dump contains 1,975,552,846 citations between 89,920,081 bibliographic resources and weighs 26.8 GB when zipped (171 GB unzipped).

Table 3. A sample taken from the OC Index CSV dump. The first column represents the attributes (columns in the CSV) of the corresponding citation. The citation timespan is represented using the duration XSD datatype (Biron & Malhotra, 2004) having the shape "PnYnMnD", where "P" indicates the period, "nY" indicates the number of years, "nM" indicates the number of months, and "nD" indicates the number of days.

Methodology

To answer our two research questions, we defined a methodology that uses the two datasets described in the previous subsection as input to compare bibliographic data in IRIS against those in OpenCitations. The methodology is summarised in the workflow diagram shown in Figure 1. The workflow comprises five steps, each managed by a dedicated tool (graphically represented by a circle with an engine icon). The diagram also includes the numerical outcomes of each step. We provide a step-by-step explanation of the workflow, detailing the processes involved and the output obtained at each stage.

Figure 1. Overview of the workflow for the adopted methodology. The workflow consists of five steps, beginning with the entire collection of bibliographic resources from IRIS, refining the data, and culminating in a comparison with the OC Meta and Index datasets. Output numbers for each step are also reported.

Trimmer

In this initial stage, we collect all bibliographic entities indexed in IRIS and categorise them based on whether they are associated with permanent unique identifiers (PIDs) from the IRIS dataset. Precisely, we extract entities in IRIS including DOI, ISBN, or PMID identifiers, as these are the only ones present in the IRIS dump and OC Meta.

Of the 304,983 entities in the IRIS dump, we found 201,471 with at least one of these PIDs. From this filtering process, we created the first of our novel datasets, *Iris No ID* (INOID from now on) (Zilli et al., 2024e), containing the metadata of 103,481 IRIS entities without a DOI, ISBN, or PMID. The remaining 201,471 entries with at least one of the PIDs supported in OC Meta are used to build the list of unique identifiers.

Validator

For each bibliographic resource (BR from now on) in IRIS, we select one of the three PIDs, prioritising DOIs, PMIDs, and ISBNs. This heuristics prioritises DOIs and PMIDs because they directly identify content, such as articles and datasets, which are central to our dataset. ISBNs,

as identifiers for books that often serve as containers (i.e. the venue) of aggregated knowledge, are considered only as a fallback when content-specific identifiers are unavailable. In cases in which one BR has more than one identifier available, the first is picked. Malformed identifiers are sanitised (e.g. removing the leading zeros from PMIDs and removing hyphens and spaces from ISBNs), and syntactically invalid ones are discarded by extracting only the identifiers with valid patterns using regular expressions, as exemplified in Table 4. All identifiers are normalised following the OC naming convention used in the OC Meta CSV files – *prefix:identifier*, where *prefix* indicates the identifier type (e.g. doi, pmid, isbn) and *identifier* is the literal string of the identifier in lowercase. Table 5 summarises the number of identifiers before and after the filtering, validation, and normalisation process.

PID Type	BR IDs in IRIS	Discarded/normalised
	10.3303/CET1543057	doi:10.3303/cet1543057
DOI	10. <u>193</u> /infdis/jiu617	discarded

ISBN	<u>88.6080.002.1</u>	discarded
	(OBRA COMPLETA):; (VOL. I)	discarded

Table 4. Examples from the filtering, validation, and normalisation process. All issues recognised during the validation, that brings to the discarding of an identifier, are underlined.

Table 5. Number of entities with DOI, ISBN, and PMID before and after the validation process.

PID Type	IRIS count	Invalid PID count	Valid PID count
DOI	131,048	123	130,925
PMID	45,855	4	45,851
ISBN	81,526	831	80,695
Total	258,429	958	257,471

Deduplicator

The output of the previous step undergoes a process of deduplication to remove the 42,720 cases in which we found the same PID associated with multiple IRIS entries. This may be the result of different scenarios, including either the production of duplicated records, e.g., when two

distinct UNIBO authors add to IRIS the same entity twice, or the specification of the same identifier for a bibliographic resource and its venue (e.g., the same ISBN specified to a book and to all the chapters it contains).

To address these instances, we act on DOIs, ISBNs and PMIDs separately, establishing a priority system that ranks the duplicated BRs based on their type and allows us to pick the preferred one. This system, implemented according to the priorities of the types of bibliographic resources described in Tables 6 and 7 (the lower number, the bigger priority), has been devised following the manual investigation of sample duplicate records, which led to the discovery that only five types ensure that the final dataset includes only the most relevant and accurate entries filtered between DOIs and ISBNs.

The approach works as follows. First, we gather all the BRs having the same DOI specified. Then, we order them according to their type, following the priority number determined for the BR types in Table 6, and simply pick the first out of the ordered entities. This method allows us to deduplicate BRs that share the same type, as well as BRs with different types. For instance, if we have three entities with the same DOI, and two have been defined as journal articles and the other as a proceeding article, we deduplicate them as a single entity, choosing the journal article as its final type, having better priority than the proceeding article. We run a similar approach for ISBNs, applying the priority specified in Table 7, while for the deduplication of PMID, we just choose the first out of the duplicate entities as they all share the same type.

The cases addressed with these priority tables mostly involved multiple entries referring to the insertion of the same PID for both content (e.g. a book chapter) and container/venue (e.g. a book). By the end of this process, we had a list of 169,685 unique BRs, reduced from the original 258,429 BRs, as described in Table 8.

Table 6. DOI priority table. The first column indicates the related BR type we used for alignment
purposes in OC Meta. In contrast, the second column lists the IRIS type specified in the IRIS
dataset (with its Italian label). A lower number (third column) has a higher priority for that type.

OC Meta type	IRIS type	Number
Journal article	1.01 Articolo in rivista	0
Book	3.02 Curatela	1
Book chapter	2.01 Capitolo / saggio in libro	2
Proceedings article	4.01 Contributo in Atti di convegno	3

Table 7. ISBN priority table. The first column indicates the related BR type we used for alignment purposes in OC Meta. In contrast, the second column lists the IRIS type specified in the IRIS dataset (with its Italian label). A lower number (third column) has a higher priority for that type.

OC Meta type	IRIS type	Number
Book	3.01 Monografia	0
Journal article	1.01 Articolo in rivista	1

Table 8. Number of BRs uniquely identified by a DOI, PMID (a	and not by a DOI), and ISBN (and
not by a DOI nor PMID) after deduplication.	

PID schema	Final Unique PIDs count
DOI	129,906
PMID	1,852
ISBN	37,927
Total	169,685

Comparator

At this stage, we extract the data from the OC Meta dataset. We look for the BRs in the current collection of IRIS, obtained in the previous passage, in the OC Meta dataset. During this process, we identified that 2,121 unique BRs appear two or more times in OC Meta – where the same IRIS BR appears multiple times with different OMIDs. We remove these duplicates, keeping the first occurrence we found in OC Meta.

This action allows us to create the two primary output datasets for our study, *Iris in Meta* (IIM, from now on) and *Iris Not in Meta* (INIM, from now on) (Zilli et al., 2024d), which contain all deduplicated IRIS BRs that are included and not included in OC Meta, respectively.

Citation Scanner

In the final stage, we run a preliminary citation analysis of the IRIS BRs in IIM. This is achieved by looking for citation links in the OC Index involving any BRs as citing or cited entities. As a result, a new dataset, *Iris in Index* (III, from now on) (Zilli et al., 2024c), has been created. Specifically, this dataset is constructed by extracting all OMIDs from the IIM and filtering the OC Index dataset to identify all citations where an OMID from the list appears as the cited or the citing entity.

Results

In this section, we present and highlight key results derived from the analysis of the four datasets produced by running our methodology: Iris No ID (INOID), Iris in Meta (IIM), Iris not in Meta (INIM), and Iris in Index (III). These results provide critical support for our discussion of addressing the research questions introduced in Section "Introduction."

BRs types

The number of records in IIM amounts to 115,083 rows, representing 67.8% of the list of deduplicated PIDs extracted from IRIS and 37.7% of the unfiltered IRIS dump (Amurri et al., 2024). The complete breakdown of IRIS publication types as included in the deduplicated IRIS dataset and IIM is provided in Appendix 1, showing that journal articles have the highest coverage rate at 90.1%, followed by brief publications (79.0%, which shows a minimal number of items in IRIS) and conference proceedings (48.2%).

Comparing the types of the BRs as described in IRIS and OC Meta, according to the data in IIM, also reveals some interesting insights on the extent to which the types align between the two systems. We analysed the types of IRIS BRs in IIM and the corresponding OC Meta types resulting from the type alignment we performed (introduced in Appendix 2). Then, we checked the number of BRs that respected such an alignment according to the type we retrieved from OC Meta. This analysis shows that most BRs (108,036) have a coherent type between the two datasets, while a smaller portion (7,047 BRs) shows a different BR type in IRIS and OC Meta. As shown in Figure 2, there is a more heterogeneous and diversified distribution for types when the number of BRs of that IRIS type is significant. In contrast, perfect matches are observed only for specific types, such as series, computer programs, and book series, often represented by a single item.

Figure 2. Overview of the mismatching types between IRIS and Meta.

BRs with no PIDs

Analysing INOID, we found that 33.9% of the BRs in the original IRIS data dump do not have any of the PID schemes that OC Meta collects in their databases. The distribution of entries in this dataset, shown in Table 9, highlights a predominance of journal-based products, with relatively fewer contributions for books and reviews.

IRIS type	count
1.01 Articolo in rivista	37,670
4.02 Riassunto (Abstract)	16,356
4.01 Contributo in Atti di convegno	13,267
2.01 Capitolo / saggio in libro	6,666

Table 9. Overview of the top 5 types of BR in the INOID dataset.

IRIS type	count
1.03 Recensione in rivista	5,343

BRs not in OpenCitations Meta

From the INIM, we discovered that 32.1% of the PIDs stored in the list created from IRIS and searched within OC Meta did not find a match. The vast majority of this portion of BRs comprises entities for which only the ISBN identifier was found while extracting the list of PIDs from IRIS. We identified 37,763 ISBNs, 15,915 DOIs, and 926 PMIDs that are not present in OpenCitations Meta. Table 10 provides a detailed breakdown of the five most frequently occurring types of BRs missing from OC Meta.

IRIS type	count
2.01 Capitolo / saggio in libro	19,102
1.01 Articolo in rivista	11,009

3.01 Monografia / trattato scientifico in forma di libro	6,372
3.02 Curatela	2,692

Table 10. Overview of the top 5 types of the IRIS BRs not present in OC Meta.

Duplicated BRs

While extracting the list of identifiers from IRIS, we identified cases where IRIS entries were associated with more than one PID. Specifically, 42,720 duplicates were found, involving 11,771 PIDs linked to more than one IRIS entry. This issue is particularly prevalent with ISBNs, as most duplications stem from incorrect aggregation of content and container identifiers.

Indeed, it is common in IRIS to find entries for distinct items sharing the same PID, where the PID does not explicitly refer to any of the individual items but rather to the larger container (i.e. the venue) that holds them. A clear example of this issue is the case of 275 IRIS entries, which represent a series of individual entries from the *Dizionario Bibliografico degli Italiani*, all linked to the same ISBN of the volume of the dictionary in which they are contained. This pattern is frequently observed in similar cases involving dictionary or encyclopedia entries, book chapters, proceedings articles, and journal articles. Table 11 summarises the number of duplicate BRs in IRIS grouped by PID schema.

duplicate PID schema	BR count
ISBN	40,856
DOI	1,851
PMID	13
total	42,720

Table 11. The number of duplicate BRs in IRIS by PID schemas.

BRs in OC Index

As derived from III, the total count of the OC Index citations involving deduplicated IRIS BRs amounts to 7,723,941. Table 12 breaks this number down by counting the number of times IRIS BRs take on the role of citing entities (in 3,787,267 citations) and cited entity (in 4,290,096 citations), with an overlap (i.e. IRIS BRs as both citing and cited entities) of 353,422 citations.

Table 12. Count of the citations in III involving IRIS BRs.

Role of IRIS BR	Citation count
Citing	3,787,267
Cited	4,290,096
Citing and Cited	353,422

Discussion

According to the IRIS dump analysed, of the overall 304,983 BRs in IRIS, 37.7% (115,083) is included in OC Meta (RQ1). Two possible factors can explain this partial coverage. On the one hand, it is important to stress that OC Meta only includes bibliographic resources that take part (either as citing entity or cited entity) in citations included in the OC Index. While the latter collection includes more than two billion citation links, OpenCitations does not have all the possible citation links existing in the literature since that information is lacking from the primary sources used for creating the OC Index. For instance, if a BR available in IRIS has no (incoming and outgoing) citation links in the OC Index, that is not included in OC Meta by construction – resulting in a missing for the present study. However, this issue can be addressed, for instance, by complementing OpenCitations data with those coming from other open sources, such as OpenAIRE (Manghi et al., 2012) and OpenAlex (Priem et al., 2022) for traditional publications and other archives and repositories for different kinds of research outcomes – e.g. Software Heritage (Di Cosmo & Zacchiroli, 2017).

On the other hand, IRIS includes many types of research outputs (as summarised in Appendix 1) that go beyond those usually available in existing (open and closed) bibliographic databases. A few examples are book chapter or essay (IRIS type: 2.01 Capitolo / saggio in libro),

monograph or scientific book (3.01 Monografia / trattato scientifico in forma di libro), curatorship (3.02 Curatela), legal comment (2.06 Commento giuridico), abstract in journal (1.06 Abstract in rivista), databases (7.05 Banche dati). In this case, a possible path to fulfil this gap is to work systematically with open infrastructures to create, at least, alignments to enable different systems to technically and semantically interoperate and to enable filling the gap in one system (e.g. UNIBO IRIS) with information in another system (e.g. OpenCitations) and vice-versa. Such layers of system interoperability are one of the core pillars studied and investigated by several task forces – and introduced related reports (Corcho et al., 2021; Kakaletris et al., 2023; Nyberg Åkerström et al., 2024) – working on the European Open Science Cloud (EOSC) (Burgelman, 2021) set up by the EOSC Association (https://eosc.eu) in the past years. Recent efforts in this direction have been devised and proposed in the context of the RDA Scientific Knowledge Interoperability Framework (SKG-IF) Graphs Working Group (https://www.rd-alliance.org/groups/scientific-knowledge-graphs-interoperability-framework-skg-if -wq/), which proposed a set of specifications (https://skq-if.github.io) to simplify the exchange of metadata about research products and their related contextual information.

We have also analysed the number of incoming and outgoing citations that involve IRIS BRs included in OpenCitations Meta (RQ2). The number of citations IRIS BRs receive is particularly important for local and national-wide activities, particularly those related to research assessment exercises. Currently, the main platforms adopted at a national level for extracting such information – as required by the *Italian National Agency for the Evaluation of Universities and Research Institutes* (in Italian: Agenzia Nazionale di Valutazione del Sistema Universitario e della Ricerca, or ANVUR – <u>https://www.anvur.it/</u>) – are proprietary services, i.e. Scopus (Baas et al., 2020) and Web of Science (Birkle et al., 2020). As of 7 January 2025, as kindly computed by the Planning and Communication unit of the University of Bologna, the number of citations received by IRIS BRs (that include those in our dataset plus all the BRs added in the meantime) that are also included in SCOPUS (138,201 distinct BRs) are 5,074,320, while they are 4,350,794 for Web of Science – involving 124,188 cited distinct IRIS BRs it includes.

Thus, from a quantitative point of view, the number of incoming citations from these proprietary services is greater than that of the OC Index – 4,290,096, close to the citation count returned by Web of Science. However, the numbers from Scopus and Web of Science are inflated by all the citations from publication entities that these two databases have added between the last published version of OC Meta and OC Index (in July 2024) and the beginning of January 2025. Indeed, to make these data more comparable, while considering different timeframes for the data gathering, we have measured the average amount of citations received by IRIS BRs included in Scopus, Web of Science, and OpenCitations – as summarised in Table 13. The table shows that the average number of citations per BR in OpenCitations outperforms those of the two proprietary services – 37,28 citations per BR against 36,72 (Scopus) and 35,03 (Web of Science). This may suggest that the distance in coverage of OpenCitations with the other proprietary database may be lesser than what is observed in the pure quantitative counting above. However, it is necessary to replicate the analysis once new OpenCitations data is available – in Q1 2025 – and to apply additional statistics (e.g. standard deviation) to confirm this speculation.

Source	IRIS BRs in source	Citations to IRIS BRs	Citations / BRs ratio
Scopus	138,201	5,074,320	36,72 citations per BR
Web of Science	124,188	4,350,794	35,03 citations per BR
OpenCitations	115,083	4,290,096	37,28 citations per BR

Table 13. Count of the citations in III involving IRIS BRs.

Another interesting analysis point in this context is the overlap of the citing entities that cite IRIS BRs in the three sources. It would be important to see, for instance, if the coverage of the citing entities involved in each citation pointing to IRIS BRs is similar across the three sources or, instead, is partially overlapping and complementing each other. However, for running such an analysis, we would need the open availability of the complete citation data from all three sources, thus comprising information about the basic bibliographic metadata of all the citing entities and the actual link between the citing entities and the IRIS BRs. However, this information is only openly available in OpenCitations data since the citations in Scopus and Web of Science are grouped, and only the citation count is available for this study. This situation again stresses the importance of having available open research information, particularly when running comparative studies.

Comparing OC Meta and UNIBO IRIS, we have noticed that 6% of the IRIS BRs included in OC Meta (7,047) have different publication types between the two sources. These mismatches could impact the accuracy of our analysis, especially when comparing publication types in OC Meta and IRIS. Further study for such mapping is necessary in the future and should consider the OC Meta documentation (https://github.com/opencitations/metadata/blob/master/documentation/csv_documentation-v1_1_0.pdf) for the complete uptake of bibliographic resource types.

Conclusions

In this work, we have presented the result of an analysis where we have compared the publications' metadata contained in the institutional bibliographic database of the University of Bologna, i.e. UNIBO IRIS, with an Open Science infrastructure containing the same kind of open research information, i.e. OpenCitations. The study's main aim has been to check, on the one hand, the current coverage of the IRIS' publications in OpenCitations and, on the other hand, to see the availability of citations for all these matched publications. The results have shown how, potentially and in perspective, open research information systems can be adopted and replace the currently used closed information systems, at least in the context of the University of Bologna.

Further studies, locally (within the University of Bologna) and globally (involving other universities among the signatories of the Barcelona Declaration, for instance), should be

performed to confirm this initial speculation. Indeed, the final research question that, in the future and with a coordinated effort across universities, institutions and infrastructures, we would like to answer should be: is the open research information currently available enough to implement the transition from closed to open systems aimed by the Barcelona Declaration? To address this issue, we must gather evidence from different institutional and applicative contexts and use as many potential sources of open research information as possible. Indeed, it is unlikely we will have, in the future, a unique open research information system with all the metadata to handle all the potential activities and needs of different institutions across the world. Instead, a federation of providers of open research information, coordinated between them and technically/semantically interoperable, may better serve the needs of the scholarly community.

Considering the work presented in this paper, we are planning further activities for the following months. One material produced and used as a consequence of the present work is the publication of the UNIBO IRIS dataset in CC0 to maximise its reuse in several contexts beyond this analysis and to comply with the Barcelona Declaration's *openness* commitment. We aim to keep the dataset updated by releasing future versions of it every year, initially, and then every six months. In addition, the scripts developed for filtering the data from the original IRIS dump to create the current dataset – which avoids the presence of personal information, as explained in Section "Data reused", will also be tested with other IRIS installations external to the University of Bologna. In principle, this would allow us to have an implemented methodology to be reused, at least in the Italian context, to enable and facilitate the creation of dumps of open metadata about the Italian scholarly publication landscape.

Finally, from the data production perspective, we plan to run the analysis introduced in this paper again once OpenCitations releases the updated versions of its collections. This step is necessary to confirm or not the conjectures stated in Section "Discussion", in particular those related to the potential replacement of closed systems with data coming from open infrastructures. In addition, along these lines, we aim to initiate an active collaboration with OpenCitations to devise strategies and protocols to potentially extend the coverage of IRIS BRs in OC Meta by implementing plugins for ingesting IRIS-compliant data into OpenCitations collections – e.g. by processing all the entities in the dataset *Iris no ID*. The new ingestion workflow, recently implemented by OpenCitations (Moretti & Heibi, 2023), enables the creation of components for plugging additional sources of bibliographic metadata and citation data in and can be used to facilitate the processing of these missing data in IRIS. Such components will, in principle, allow any IRIS installation to be interoperable with OpenCitations, thus enabling the increment of coverage of Italian publications within such an Open Science infrastructure.

Acknowledgement

This work has been partially funded by the European Union's Horizon Europe framework programme under Grant Agreement No 101095129 (GraspOS Project).

This study was based on the outcomes of the analysis held during the Open Science 2023/2024 course (https://www.unibo.it/en/teaching/course-unit-catalogue/course-unit/2023/443753) of the Second Cycle International Degree in Digital Humanities and Digital Knowledge (https://corsi.unibo.it/2cycle/DigitalHumanitiesKnowledge) of the University of Bologna, taught by SP. We thank all the people who participated in the workshop organised in the context of the Open Science course who provided insightful feedback and, thus, implicitly contributed to some of the aspects of the present study. Also, we want to thank Elena Giachino from the Planning and Communication unit (APPC) and Alberto Amurri from the IT Systems and Services unit (CeSIA) of the University of Bologna for having provided the raw UNIBO IRIS we elaborated to produce the IRIS dataset used in this study, and, again, Elena Giachino for having provided crucial statistics about IRIS BRs in Scopus and Web of Science, including their related citation counts.

Conflict of interest

SP is the University of Bologna's representative for the Barcelona Declaration and Director of OpenCitations. IH is the Chief Technology Officer of OpenCitations. OpenCitations is one of the open infrastructures that formally supports the Declaration.
