

GeoPix: Multi-Modal Large Language Model for Pixel-level Image Understanding in Remote Sensing

Ruizhe Ou, Yuan Hu*, Fan Zhang, Jiaxin Chen, Yu Liu

Abstract—Multi-modal large language models (MLLMs) have achieved remarkable success in image- and region-level remote sensing (RS) image understanding tasks, such as image captioning, visual question answering, and visual grounding. However, existing RS MLLMs lack the pixel-level dialogue capability, which involves responding to user instructions with segmentation masks for specific instances. In this paper, we propose GeoPix, a RS MLLM that extends image understanding capabilities to the pixel level. This is achieved by equipping the MLLM with a mask predictor, which transforms visual features from the vision encoder into masks conditioned on the LLM’s segmentation token embeddings. To facilitate the segmentation of multi-scale objects in RS imagery, a class-wise learnable memory module is integrated into the mask predictor to capture and store class-wise geo-context at the instance level across the entire dataset. In addition, to address the absence of large-scale datasets for training pixel-level RS MLLMs, we construct the GeoPixInstruct dataset, comprising 65,463 images and 140,412 instances, with each instance annotated with text descriptions, bounding boxes, and masks. Furthermore, we develop a two-stage training strategy to balance the distinct requirements of text generation and masks prediction in multi-modal multi-task optimization. Extensive experiments verify the effectiveness and superiority of GeoPix in pixel-level segmentation tasks, while also maintaining competitive performance in image- and region-level benchmarks.

Index Terms—Remote Sensing, Multi-modal Large Language Model, Multi-referring Segmentation, Memory Bank

I. INTRODUCTION

MULTI-MODAL large language models (MLLMs) in remote sensing (RS) have demonstrated outstanding performance on multi-modal tasks such as image captioning, visual question answering (VQA), and visual grounding. For example, RSGPT [1] adapted a pre-trained MLLM to the RS domain, marking it as the first model to support image-level multi-modal tasks such as image captioning and image-level question answering. Subsequent RS MLLMs [2]–[9], such as GeoChat [2], SkyEyeGPT [3], EarthGPT [4], have

Image Caption

USER: Describe the image in detail.
 GEOPIX: The image features a suburban area with houses, roads, and two storage tanks. The storage tanks are small in size and are positioned within the frame: one towards the top-middle, while the other is located towards the bottom of the image. There are several small vehicles scattered throughout the image, particularly on the right side, along with some trees and grass.

Multi-referring Segmentation

USER: Give me the segment masks of the large storage tank and the storage tank that is a little smaller than the large storage tank.
 GEOPIX: Sure, there are [SEG] and [SEG]

USER: What is the gray rectangular basketball court on the left in this image? Please respond with segmentation mask.
 GEOPIX: Sure, it is [SEG]

USER: What is the vehicle that is on the middle of right, the vehicle on the lower right and the vehicle on the upper right. Please respond with segmentation masks.
 GEOPIX: Sure, it is [SEG], [SEG] and [SEG]

Visual Question Answering

USER: Is there a vehicle located at the lower right in the image?
 GEOPIX: Yes

USER: What is the main type of area shown in the image?
 GEOPIX: residential

USER: What object class is the vehicle on the middle of right?
 GEOPIX: small-vehicle

USER: How many storage tank are visible in the image?
 GEOPIX: 2

Visual Grounding

USER: Where is the storage tank that is a little smaller than the large storage tank?
 GEOPIX: {<37>...<44>}

USER: Where is the intersection in the upper left corner of the image?
 GEOPIX: {<19>...<18>}

Fig. 1. Overview of GeoPix capabilities in multi-modal, multi-task remote sensing image interpretation through dialogue. GeoPix supports image-level tasks, including image captioning and visual question answering, as well as region-level tasks like visual grounding. Additionally, it expands its functionality to pixel-level tasks, specifically multi-referring segmentation, as depicted in the purple panel.

advanced to include region-level dialogue capabilities. These models support tasks such as region captioning, which involves generating captions for specific image regions based on user instructions, and visual grounding, where bounding boxes are predicted for instances in response to user prompts. However, existing RS MLLMs lack pixel-level dialogue capabilities, namely, the ability to generate pixel-level segmentation masks for specific instances based on user instructions.

To this end, we introduce GeoPix in this study, a RS MLLM that extends dialogue capabilities from image- and region-level to pixel-level image understanding. Specifically, GeoPix supports image-level tasks including image captioning and visual question answering, as well as region-level tasks like visual grounding. Moreover, it extends support to pixel-level tasks, including referring segmentation and multi-referring segmentation. Notably, we devise a Class-wise Learnable Memory (CLM) module to facilitate instance segmentation. The core component of the CLM module is a memory bank that extracts and stores class-wise, instance-level geo-context

across the entire dataset during training. During inference, the CLM retrieves the learned class-wise features from the memory bank to enhance the segmentation of the current instance as specified by the user.

In addition, the remote sensing field suffers from a lack of large-scale multi-modal datasets that simultaneously provide instance-level text descriptions, bounding boxes, and segmentation masks, which hampers the development of pixel-level RS MLLMs. To address this gap, we constructed the GeoPix-Instruct dataset, based on RSVG [10] and SAMRS [11]. GeoPixInstruct is a comprehensive large-scale remote sensing multi-modal dataset encompassing 65,463 images and 140,412 instances. Each instance is annotated with pixel-level masks, bounding boxes, and text descriptions, providing the support of pixel-level multi-modal tasks, such as multi-referring segmentation. Generating accurate descriptions for instances in remote sensing imagery is often challenging due to the varying spatial arrangements of objects, including isolated instances, linear arrangements, and clustered groupings. To address this, we develop a description generation pipeline based on GPT-4o, which identifies the spatial arrangement of instances and generates instance-level descriptions using provided examples for each arrangement type. To further enhance the accuracy of the generated descriptions, we manually verify a portion of the data and use it for vision fine-tuning of GPT-4o. Tab. I provides a comparison between GeoPixInstruct and existing remote sensing multi-modal datasets.

In the optimization of pixel-level multi-task MLLMs, a tug-of-war problem arises: text generation typically requires fewer training steps to converge effectively, whereas segmentation demands extended training to achieve precise mask predictions. To address this, we introduce a two-stage training strategy that balances the distinct requirements of text generation and pixel-level mask prediction. Specifically, in the first stage, our training focuses on equipping the model with text generation capabilities in the RS domain using fewer training steps, while introducing segmentation tokens to provide the model with initial mask prediction abilities. In the second stage, our training shifts its focus toward enhancing mask prediction accuracy by increasing the proportion of pixel-level training data and extending the training duration. The two-stage strategy allows GeoPix to achieve state-of-the-art performance in multi-referring segmentation, while also delivering competitive or superior performance on image- and region-level multi-modal benchmarks. Our contributions can be summarized as follows:

- We propose GeoPix, a pixel-level RS MLLM that simultaneously supports image-, region- and pixel-level image understanding.
- We devise a class-wise learnable memory module to effectively enhance segmentation accuracy and consistency of multi-scale objects in RS imagery.
- We construct the GeoPixInstruct dataset, which is a large-scale remote sensing multi-modal dataset that provides text descriptions, bounding boxes, and pixel-level masks for each instance.
- We develop a two-stage training strategy to manage the conflicting training requirements of text generation and

mask prediction during the optimization.

II. RELATED WORKS

A. Multi-modal Large Language Models

The typical architecture of existing multi-modal large language models (MLLMs) typically integrates a pre-trained multi-modal vision encoder with a large language model (LLM) via a linear layer or a MLP. This integration is achieved by concatenating visual tokens and text tokens, enabling the LLM to process multi-modal information simultaneously. Models such as LLaVA [15]–[17], MiniGPT4 [18], [19], Qwen-VL [20], and others [21]–[27] leverage this approach to maintain strong language capabilities of LLM while supporting image-level and region-level multi-modal tasks, including image captioning, visual question answering, and visual grounding. However, these models lack the capability for pixel-level image understanding. Subsequent models have addressed this issue; for example, LISA [28] achieves this by integrating SAM [29] with an LLM, while PixelLM [30] accomplishes it by redesigning a multi-scale mask decoder and integrating it into the LLM. These models establish a separate visual pathway to predict pixel-level masks conditioned on the output embeddings of LLM. Overall, these approaches extend the MLLMs’ capability to handle more fine-grained visual tasks, such as pixel-level segmentation.

B. Remote Sensing Multi-modal Large Language Models

Existing remote sensing (RS) MLLMs have demonstrated capabilities in image-level and region-level image understanding, enabling tasks such as image captioning, visual question answering, and visual grounding. For instance, RSGPT [1] was the first to adapt a pre-trained MLLM to the RS domain, supporting image-level tasks including image captioning and image-level question answering. Models like GeoChat [2], SkyEyeGPT [3], and others [4]–[9] extended these capabilities to the region-level, supporting tasks like grounded image captioning, region-specific visual question answering, and visual grounding. While the aforementioned RS MLLMs have achieved image-level and region-level dialogue capabilities in the RS domain, pixel-level RS MLLMs have not yet been thoroughly explored. Current models with pixel-level vision-language capabilities [12], [13], are limited to image interpretation tasks like referring image segmentation and lack the conversational abilities of a LLM. Therefore, GeoPix is

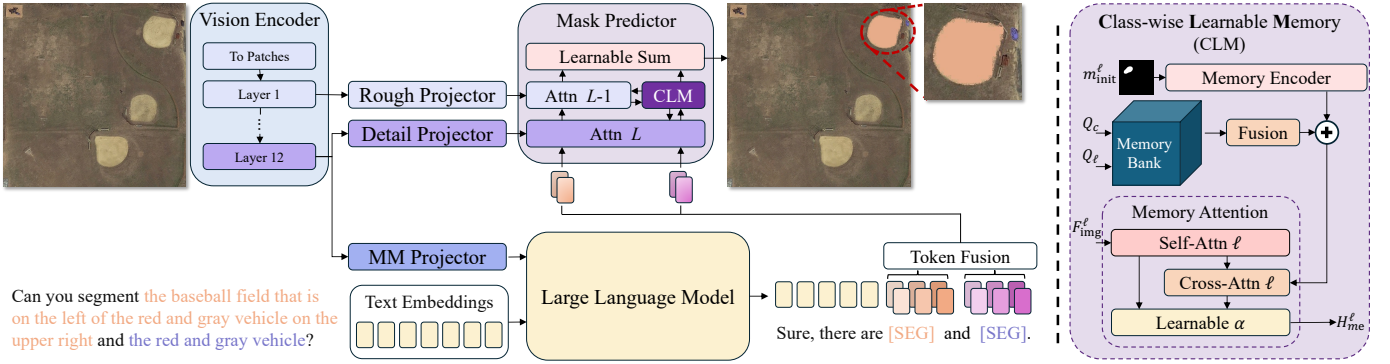

Fig. 2. Overview of the proposed GeoPix model architecture and the detailed design of the class-wise learnable memory (CLM) module. The left panel illustrates the overall architecture of GeoPix. GeoPix takes user text instructions and images as input and outputs corresponding answers and segmentation results (if the user’s instruction requests single or multiple object segmentation). The user-input image is encoded to extract multi-scale visual features via the vision encoder. These features are transformed by independent projectors and fed into both the mask predictor and the LLM. The LLM processes the instructions along with the deepest scale of visual features to predict interleaved text and segmentation tokens. Subsequently, the segmentation tokens serve as conditions for the mask predictor, guiding it to predict masks for the instances specified by the user. The right panel showcases the detailed design of the CLM module. The CLM module first encodes the initial mask m_{init}^ℓ of each scale ℓ into latent representations using the memory encoder, and then retrieves memory features from the memory bank using the category query Q_c and scale query Q_ℓ . The memory features are combined with the encoded initial mask via element-wise addition. Finally, the aggregated features serve as the key and value in the memory attention module, enhancing the visual features to obtain memory-enhanced features H_{me} .

specifically designed to fill this gap by establishing a pixel-level RS MLLM.

C. Remote Sensing Multi-modal Datasets

In the field of RS, existing open-source multi-modal datasets only support image-level and region-level multi-modal tasks. For example, RSICap [1] contains only image-text pairs and facilitates image-level tasks such as image captioning and visual question answering. GeoChatInstruct [2] and VRS-Bench [14] are built on existing object detection datasets [10], [11], [31]–[33] by automatically generating text descriptions for objects or regions within images using rule-based methods or GPT models, enabling region-level tasks like grounded image captioning, region-specific question answering, and visual grounding. However, datasets with pixel-level image-text labels, such as RefSegRS [12] and RRSIS-D [13], are designed for referring image segmentation tasks. They do not include bounding box labels, their annotations are not intended for instruction-following, and they are relatively small in scale. Therefore, we constructed a large-scale dataset to support the training of pixel-level RS MLLMs.

D. Memory Bank

Memory banks have been widely employed in computer vision tasks such as classification [34]–[36], detection [37]–[39], and segmentation [40]–[42], enhancing performance by learning and storing shared features during training and integrating them into predictions for new inputs. In segmentation [42], a class-wise memory module retains features from class-wise objects, supporting segmentation by leveraging intra-class consistency. Recently, SAM-2 [43] applied a memory bank to video instance segmentation. The memory bank in SAM-2 stores instance-level features from previous frames and uses them as conditions for segmenting subsequent frames, ensuring segmentation consistency for the

same object. Similarly, Skysense [44] introduces prototype learning in the remote sensing domain, employing a learnable approach to extract class-wise geo-context representations. By providing complementary cues, prototype learning enhances feature representations, resulting in improved performance in remote sensing tasks such as segmentation and detection. The difference between prototype learning and memory banks lies in that prototype learning employs clustering to identify class centers or prototypes, whereas memory-based methods focus on storing specific features of samples. In this study, we utilize the memory bank mechanism to store class-wise geo-context in remote sensing imagery, thus facilitating segmentation.

III. METHOD

In this section, we first introduce the overall architecture of GeoPix, then elaborate on the proposed class-wise learnable memory module, and finally, we describe the two-stage training strategy.

A. GeoPix Architecture

GeoPix is composed of three primary components: i) a pre-trained vision encoder, ii) a large language model (LLM), iii) a multi-scale mask predictor with class-wise learnable memory. The overall architecture is depicted in Fig. 2. GeoPix processes the input image and user instructions and generates interleaved text descriptions and corresponding masks for a varying number of targets.

For an input image x_{img} , the vision encoder \mathcal{E} extracts a spectrum of multi-scale visual features, represented as $\{F_{img}^\ell = \mathcal{E}(x_{img})\}_{\ell=1}^L$, where L denotes the number of visual scales. Each visual feature F_{img}^ℓ is further transformed by scale-specific projectors \mathcal{P}^ℓ , resulting in $\{F_{img}^\ell = \mathcal{P}^\ell(F_{img}^\ell)\}_{\ell=1}^L$. This forms separate visual pathways connected to the mask predictor. Additionally, the deepest visual feature F_{img}^L is processed through a multi-modal (MM) projector \mathcal{P}^L , resulting in

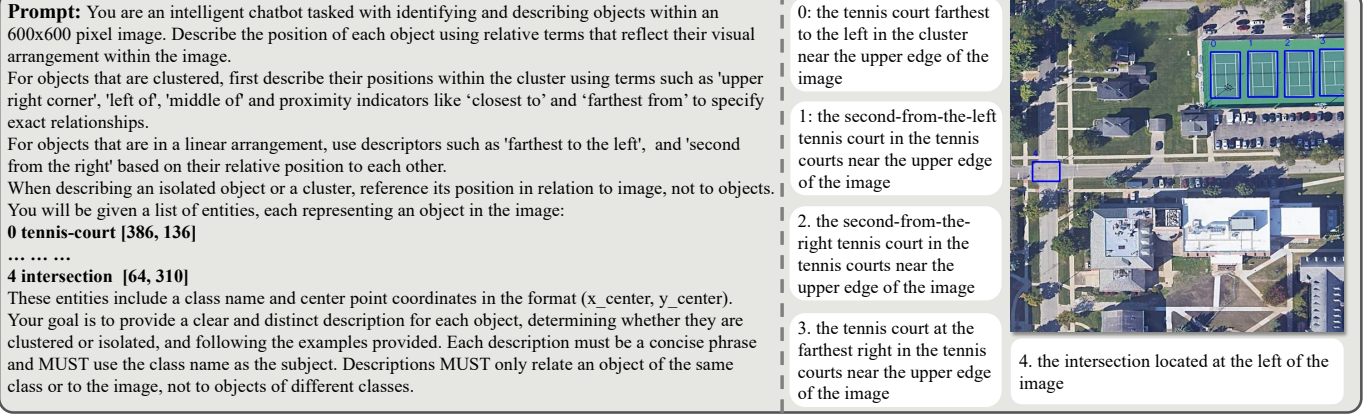

Fig. 3. The left panel displays the instruction used to prompt both GPT-4o and its fine-tuned version within our description generation pipeline. The right panel provides an example description generated by the fine-tuned GPT-4o. Bounding boxes are shown for instance differentiation and are not part of GPT-4o’s input.

$F_{llm_img} = \mathcal{P}^L(F_{img}^L)$. This output is then fed into the LLM to generate textual outputs, and segmentation tokens specifically intended to trigger the mask predictor.

Segmentation tokens are introduced into the LLM to serve as conditioning inputs following [30]. The segmentation tokens are defined as $T_{seg} = \{\tau_n^\ell \in \mathbb{R}^d\}_{n=1, \ell=1}^{N, L}$, where L represents the number of scales, N denotes the number of tokens per scale, and d is the hidden dimension of LLM. These tokens are assigned to each scale, providing scale-specific conditions for the segmentation of each instance, with their embeddings serving as conditioning inputs for the multi-scale mask predictor to facilitate the segmentation of each corresponding instance.

Conditioned by the embeddings of segmentation tokens, the mask predictor interacts with the proposed class-wise learnable memory (CLM) module to transform multi-scale visual features into precise masks. Specifically, the mask predictor first generates initial masks $M_{init} = \{m_{init}^\ell \in \mathbb{R}^{K \times H_p \times W_p}\}_{\ell=1}^L$, for each scale ℓ , where K denotes the number of targets, and H_p and W_p represent the height and width of the pixel-level masks. These initial masks are subsequently refined by the CLM module to produce more accurate segmentation masks. The final masks are obtained through a learnable summation of the masks generated from visual features at different scales, formulated as $P_{mask} = \sum_{\ell=1}^L \beta \cdot P_{mask}^\ell$, where β is learnable. In the following, we detail the design of the proposed CLM module.

B. Class-wise Learnable Memory (CLM) Module

We propose a class-wise learnable memory (CLM) module that learns to extract and store class-wise regional geo-context, thereby facilitating the segmentation of specific instances by leveraging high-level semantic information common within each category. The module consists of three components: i) a memory encoder, ii) a memory bank, and iii) a memory attention block, as depicted in the right panel of Fig. 2.

To adaptively store semantic information across different scales and categories, we design a matrix-like memory bank \mathcal{M} organized by class and scale indices. The scale of visual features and class information serve as queries to retrieve

relevant memory features H_m from the memory bank, as shown in Eq. 1.

$$H_m = \mathcal{M}(Q_c, Q_\ell) \quad (1)$$

where $H_m = \{h^\ell \in \mathbb{R}^{K \times N \times D \times H \times W}\}_{\ell=1}^L$, K and L represent the number of classes and scales. N denotes the memory capacity for expanding the storage capability of each class, and D denotes the dimension of the memory, while H and W correspond to the height and width of the memory features. Q_c and Q_ℓ denote the category query and the scale query that are used to extract class-wise geo-context of specific scale.

Building on this memory bank, we introduce a memory encoder \mathcal{I} and a memory attention block to fuse the multi-scale visual features $\{F_{img}^\ell = \mathcal{P}^\ell(F_{img}^\ell)\}_{\ell=1}^L$ and initial masks m_{init}^ℓ , resulting in memory-enhanced features H_{me} , as expressed in Eq. 2:

$$H_{me} = \mathcal{CA}(\mathcal{SA}(F_{img}^\ell), \mathcal{I}(m_{init}^\ell) + \mathcal{F}(h^\ell)) \quad (2)$$

where \mathcal{CA} and \mathcal{SA} represent cross attention and self-attention, respectively. \mathcal{F} denotes the fusion of memory features. The memory feature fusion \mathcal{F} is performed along the memory capacity N , formulated as $\mathcal{F}(h^\ell) \in \mathbb{R}^{K \times 1 \times D \times H \times W}$. $\mathcal{I}(m_{init}^\ell)$ represents the encoded pixel-level initial masks, where $\mathcal{I}(m_{init}^\ell) \in \mathbb{R}^{K \times D \times H \times W}$. The fused memory features are then combined with the encoded initial mask via element-wise addition. Memory fusion enables the learnable extraction and integration of the most valuable information from the memory capacity. The aggregated representation serves as the key and value in the \mathcal{CA} , interacting with the self-attended visual features $\mathcal{SA}(F_{img}^\ell)$ to generate the memory enhanced semantic features H_{me} . The final output is further refined through a learnable parameter α , forming a residual connection with $\mathcal{SA}(F_{img}^\ell)$ to ensure feature consistency and stability, as shown in Eq. 3:

$$H_{me} = \mathcal{SA}(F_{img}^\ell) + \alpha \cdot H_{me} \quad (3)$$

The memory-enhanced features enrich the visual features at each scale, encapsulating higher-level semantic information

across different classes and regions, leading to more accurate mask predictions.

C. Two-stage Training Strategy

Balancing multi-task training for text generation and multi-referring segmentation presents significant challenges. Text generation tasks typically achieve convergence within fewer training epochs, whereas multi-referring segmentation demands more extensive training to ensure precision. To tackle this disparity, we adopt a two-stage training strategy for GeoPix. In the first stage, the LLM is fine-tuned, while the mask predictor and the CLM module are initially trained from scratch. The model is trained for five epochs using the full VRSBench dataset in combination with GeoPixInstruct. This stage primarily focuses on adapting the pre-trained LLM’s image-level and region-level dialogue capabilities to the remote sensing domain, while simultaneously introducing segmentation tokens to facilitate initial mask prediction. In the second stage, the model undergoes further training with an emphasis on refining segmentation. At this stage, 8,000 samples are randomly selected from the VRSBench to prevent catastrophic forgetting of image-level and region-level dialogue capabilities and are combined with data from each subset of GeoPixInstruct. The proposed two-stage strategy enables progressive refinement of pixel-level segmentation performance without compromising the model’s ability to generate text. This approach ensures that the model excels in both segmentation and text generation tasks across multi-modal remote sensing applications.

IV. GEOPIXINSTRUCT: A PIXEL-LEVEL INSTRUCTION DATASET FOR REMOTE SENSING

In this section, we introduce the GeoPixInstruct dataset, a large-scale remote sensing dataset specifically designed to support the training of pixel-level RS MLLMs. GeoPixInstruct is developed based on SAMRS [11]. As shown in Tab. I, SAMRS comprises three subsets—SIOR, FAST, and SOTA—where each instance is annotated with bounding box and mask. We supplemented the SAMRS dataset with instance-level textual descriptions. Consequently, GeoPixInstruct also includes three subsets: SIOR-T (derived from SIOR), FAST-T (derived from FAST), and SOTA-T (derived from SOTA).

A. Systematic Data Filtering

When constructing the textual descriptions for each instance, our goal is to ensure that the text uniquely refers to the corresponding instance. However, remote sensing images often contain densely clustered instances of the same category, such as yacht marinas or parking lots, posing challenges for generating precise textual descriptions for each instance for such images. Therefore, we first apply predefined rules, as referenced in [10], to filter images from the existing instance segmentation dataset. Specifically, we ensure that the number of instances of the same category within a single image remains below five, and the total number of instances across different categories does not exceed eleven. This filtering process yields 65,463 images and 140,412 instances, encompassing both isolated and clustered instances.

TABLE II
STATISTICS OF GEOPIXINSTRUCT. THE SIZE REFERS TO THE WIDTH AND HEIGHT OF SQUARE IMAGES. φ REPRESENTS THE NUMBER OF INSTANCES PER IMAGE AND THE θ REPRESENTS THE MASK COVERAGE RATIO WITHIN THE IMAGES.

Subset	#Img.	#Cat.	#Inst.	Size	Avg. φ	Avg. θ
SIOR-T	17,402	20	38,320	800	2.20	4.34
FAST-T	38,565	37	77,276	600	2.61	1.12
SOTA-T	9,038	18	24,816	1024	2.00	0.94

Fig. 4. The distribution of instance number (φ) by mask coverage ratio (θ). Subset located toward the lower-left corner represent smaller instance number with lower coverage ratio, indicating higher segmentation difficulty.

B. Construction of SIOR-T

The SIOR subset of SAMRS is constructed based on DIOR [31] and shares the same images as RSVG-DIOR (RSVGD) [10]. Since RSVG provides instance-level descriptions, we integrate these descriptions with the annotations from SIOR to form SIOR-T by matching instance bounding box coordinates between the two datasets, allowing for a margin of error of 10 pixels. This integration equips SIOR-T with both instance-level descriptions and pixel-level mask annotations. In contrast, the other two subsets of SAMRS—FAST and SOTA—do not have existing open-source descriptions. To address this limitation, we designed an automatic description generation pipeline to produce instance-level descriptions for FAST and SOTA, thereby constructing the FAST-T and SOTA-T subsets.

C. Construction of FAST-T and SOTA-T

Previous works [14], [28], [30] have demonstrated the feasibility of constructing descriptions using GPT. Building upon this, we designed a two-step description generation pipeline leveraging GPT-4o. In the first step, we utilize a structured prompt to guide GPT-4o in generating initial descriptions in a zero-shot manner. A subset of these initial descriptions is then manually curated to form a fine-tuning dataset. This dataset is used for vision tuning GPT-4o, enhancing the accuracy of the generated instance-level descriptions. In the structured prompt, we guide GPT-4o to first determine the spatial arrangement status of objects, categorizing them as isolated, arranged in a line, or clustered. For isolated instances, the descriptions follow the methodology outlined in RSVG, highlighting the attributes of the instance and its spatial relationships relative to other instances. For linear and clustered instances, the descriptions begin with the relative position of the instance within the line or cluster, followed by the line or cluster’s overall position in the image. The prompt also includes a

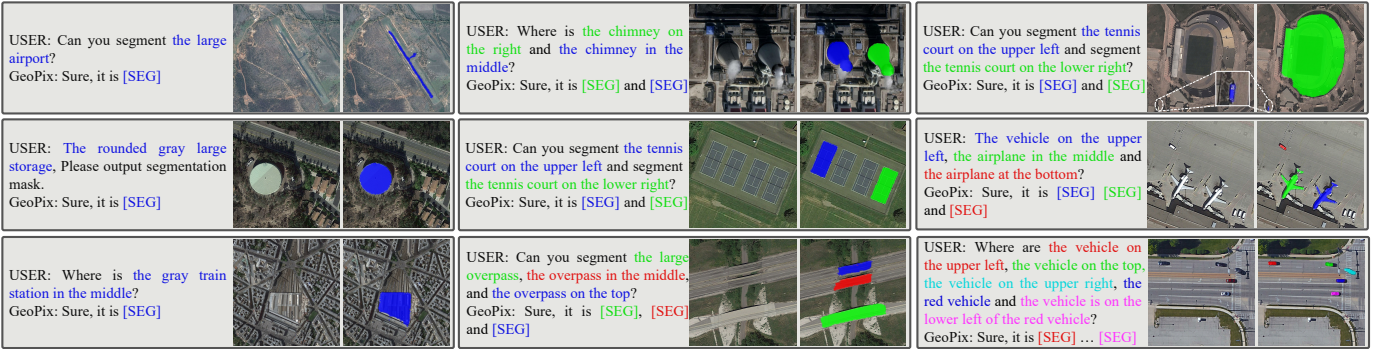

Fig. 5. Visualization of GeoPix referring segmentation results. The left panel displays single-instance referring segmentation. The middle panel showcases multi-instance referring segmentation for instances within the same category. The right panel illustrates multi-instance referring segmentation across different categories.

detailed list specifying each instance’s index, category, and center point coordinates to ensure comprehensive and accurate instructions for GPT-4o. An example of the structured prompt is shown in Fig. 3.

In the second step, to improve the accuracy of descriptions generated by GPT-4o, we implemented a refinement process involving human feedback and fine-tuning. Specifically, 100 images containing isolated instances, instances in linear arrangements, and clustered instances were randomly selected from each category for manual correction of the initial descriptions generated by GPT-4o. Descriptions exhibiting inconsistencies—particularly for clustered instances—were revised to address noise in the generated outputs. These corrected descriptions formed a high-quality fine-tuning dataset, which was subsequently used to conduct vision-based fine-tuning on GPT-4o. This iterative process enhanced the model’s ability to produce accurate and precise descriptions for instances across diverse spatial configurations, improving performance for both isolated and clustered instances.

D. Statistics

GeoPixInstruct comprises three subsets—SIOR-T, FAST-T, and SOTA-T—containing a total of 65,463 images and 140,412 instances. Each instance is annotated with a textual description, instance category, bounding box, and mask. As shown in Tab. II, we provide detailed statistics on the number of images, categories, instances, and corresponding annotations for each subset, along with the image size. Additionally, we report the average number of instances per image (φ) and the average mask coverage ratio (θ) for each subset. θ is calculated as the ratio of the pixel area of an instance mask to the total pixel area of the image. To further analyze the each subset’s characteristics, we visualize the distribution of instance counts by mask coverage ratio (θ) in Fig. 4. The three subsets exhibit distinct variations in φ and θ , with their relationship reflecting differing segmentation difficulty levels. Specifically, lower θ and fewer instances correspond to increased segmentation difficulty. Based on this, the SOTA-T subset is identified as the most challenging, followed by FAST-T, with SIOR-T presenting the lowest level of difficulty.

TABLE III

V. EXPERIMENTS

A. Implementation Details

The vision encoder, MM Projector, and LLM in our model are initialized using the pre-trained LLaVA-1.5 model, while the remaining modules are trained from scratch. The model is consistently trained at an image resolution of 336×336 . In our implementation, the vision encoder remains frozen, and LoRA [45] is applied to finetune the W_q and W_v parameters of LLM. During stage one of our two-stage training strategy, the LoRA rank r is set to 128, while in stage two, the rank r is reduced to 8. We adopt the AdamW optimizer, employing a linear warm-up phase followed by a cosine annealing learning rate scheduler. In stage one, we train for a total of 5 epochs, with the learning rate linearly increasing to 3×10^{-4} during the first epoch as a warm-up. In stage two, the learning rate follows the same warm-up schedule over 2 epochs, with training extended to 50 epochs to ensure optimal performance. The global batch size is maintained at 196 throughout the training period.

B. Multi-referring Segmentation

We first evaluate the performance of our model on the multi-referring segmentation task. We compare GeoPix with RRSIS [12], RMSIN [13], LISA-7B [28] and PixelLM-7B [30] on GeoPixInstruct in terms of mIoU and cIoU. RRSIS and RMSIN are specialized referring segmentation models in the RS domain, while LISA and PixelLM are MLLMs in general domain. All models are trained on the constructed GeoPixInstruct dataset using their original training settings. RRSIS and RMSIN can only predict one mask at a time based on a given textual description. Therefore, we enable RRSIS

Fig. 6. Visualization of additional GeoPix segmentation results across the three subsets of GeoPixInstruct. and RMSIN to perform single-instance referring segmentation multiple times to accomplish multi-referring segmentation. In contrast, GeoPix, LISA, and PixelLM can directly perform multi-referring segmentation by predicting masks for multiple instances simultaneously.

As shown in Tab. III, GeoPix outperforms the specialized models RRSIS and RMSIN on the SIOR-T subset while delivering competitive performance on the FAST-T and SOTA-T subsets. Additionally, GeoPix surpasses LISA and PixelLM across all subsets of GeoPixInstruct.

Fig.5 displays examples of GeoPix’s dialogues for multi-referring segmentation, showcasing segmentation results for a single instance, instances within the same category, and instances across multiple categories. The results show that GeoPix can accurately locate objects specified by users and produce the corresponding segmentation masks. Fig.6 presents additional segmentation results from GeoPix across the three subsets of GeoPixInstruct.

C. Visual Question Answering

We evaluate the visual question answering (VQA) performance of GeoPix on VRSEBench [14] and RSIEval [1]. On

VRSEBench, we compare GeoPix with MiniGPT4-v2 [19], LLaVA-1.5 [16], Mini-Gemini[46], and GeoChat [2], all of which are fine-tuned on VRSEBench. On RSIEval, GeoPix is compared with BLIP2, MiniGPT4 [18], and RSGPT [1], where GeoPix performs predictions in a zero-shot manner. VRSEBench consists of 9,349 images paired with 37,409 question-answer pairs, encompassing ten question types: object category, presence, quantity, color, shape, size, position, direction, scene characteristics, and reasoning. RSIEval includes 100 images with 936 question-answer pairs, covering ten categories: presence, quantity, color, absolute position, relative position, area comparison, road direction, image content, scene, and reasoning. Both benchmarks include object-level, scene-level, and reasoning-level questions, while RSIEval additionally incorporates image-level questions. To quantify model performance, we use GPT to evaluate whether predicted answers align with ground truth, calculating accuracy as the metric. Tab. IV presents the results on VRSEBench. GeoPix achieves superior performance across all question types, surpassing the previous RS MLLM GeoChat [2]. Specifically, GeoPix achieves gains over GeoChat, ranging from 1.6% (presence) to 24.4% (category), with an average overall accuracy increase of

TABLE VI
COMPARISON OF MODEL PERFORMANCE ON THE IMAGE CAPTIONING TASK IN THE RSIEVAL. ALL SCORES ARE EVALUATED AND REPORTED AS PERCENTAGES; † INDICATES MODELS W/O FINE-TUNING ON RSICAP.

Method	BLEU-1	BLEU-2	BLEU-3	BLEU-4	METEOR	ROUGE_L	CIDEr	CLAIR

TABLE VII
COMPARISON OF MODEL PERFORMANCE ON THE IMAGE CAPTIONING TASK IN THE VRSBENCH. ALL SCORES ARE REPORTED AS PERCENTAGES. BOLD INDICATES THE BEST OVERALL PERFORMANCE, WHILE UNDERLINED DENOTES THE BEST RESULT AMONG REMOTE SENSING DOMAIN-SPECIFIC MODELS.

Method	BLEU-1	BLEU-2	BLEU-3	BLEU-4	METEOR	ROUGE_L	CIDEr	CLAIR
MiniGPT4v2	36.8	22.4	13.9	8.7	17.1	30.8	21.4	73
LLaVA-1.5	48.1	31.5	21.2	14.7	21.9	36.9	33.9	78
Mini-Gemini	47.6	31.1	20.9	14.3	21.5	36.8	33.5	77
GeoChat	<u>46.7</u>	30.2	20.1	13.8	21.1	35.2	28.2	<u>77</u>
GeoPix	<u>46.7</u>	<u>30.5</u>	<u>20.6</u>	<u>14.0</u>	23.4	<u>36.3</u>	<u>31.3</u>	<u>77</u>

14%. Similarly, Tab. V presents the results on RSIEval. GeoPix demonstrates competitive or superior zero-shot performance compared to previous MLLMs, outperforming RSGPT [1] by 2%-13% in question types such as color and absolute area comparison. Overall, GeoPix demonstrates superior VQA performance compared to previous models, highlighting its effectiveness in VQA for remote sensing imagery.

D. Image Captioning

We evaluate the image captioning performance of GeoPix on VRSBench [14] and RSIEval [1]. GeoPix is compared with the same models mentioned in the VQA section. Note that GeoPix is evaluated in a zero-shot manner on RSIEval. The models are prompted with the instruction "Describe the image in detail." and the generated captions are evaluated using metrics including BLEU [47], ROUGE_L [48], METEOR [49], CIDEr [50], and CLAIR [51]. Tab. VII presents the results on VRSBench, where GeoPix demonstrates competitive performance compared with GeoChat. Tab. VI shows the results on RSIEval, GeoPix underperforms compared to RSGPT. The reason is that GeoPix learns image captioning capabilities from descriptions generated by GPT-4v on VRSBench, whereas the descriptions in RSIEval are manually annotated. The two differ in description style, content, and length, leading to GeoPix’s suboptimal performance on RSIEval.

E. Visual Grounding

We evaluate our model’s performance on the visual grounding task using the VRSBench [14], which comprises 9,318 images and 16,159 instances, covering both unique and non-unique object referring tasks. Unique objects are the only instance of their category in the image, while non-unique objects have multiple instances, requiring more precise descriptions for accurate localization. We report performance in terms of A@0.5 and A@0.7, representing accuracy at IoU thresholds of 0.5 and 0.7, respectively. As shown in Tab. VIII, GeoPix achieves competitive performance on non-unique object referring tasks, with an accuracy of 44.8% at A@0.5 and 18.2%

TABLE VIII
COMPARISON OF MODEL PERFORMANCE ON THE VISUAL GROUNDING TASK IN THE VRSBENCH. A@0.5 REPRESENTS ACCURACY FOR PREDICTIONS WITH IOU OVER 0.5, WHILE A@0.7 DENOTES ACCURACY AT A STRICTER IOU THRESHOLD OF 0.7.

Method	Unique		Non-Unique		All	
	A@0.5	A@0.7	A@0.5	A@0.7	A@0.5	A@0.7
MiniGPT4v2	40.7	18.9	32.4	15.2	35.8	16.8
LLaVA-1.5	51.1	16.4	34.8	11.5	41.6	13.6
Mini-Gemini	41.1	9.6	22.3	4.9	30.1	6.8
GeoChat	57.4	22.6	44.5	18.0	49.8	19.9
GeoPix	57.0	22.7	44.8	18.2	49.8	20.0

at A@0.7. Compared to GeoChat [2], GeoPix improves by 0.3% at A@0.5 and 0.2% at A@0.7, demonstrating consistent enhancements in our model’s capability for the region-level image understanding task.

F. Ablation Studies

We conduct ablation studies on memory capacity, memory fusion strategies, projector strategies, and the proposed two-stage training strategy of GeoPix. These ablation experiments are performed and evaluated on the SIOR-T subset.

1) *Memory Capacity*: The memory capacity is utilized to enhance the ability of the memory bank to store representative class-wise geo-context. We evaluate the impact of memory capacity $N \in \{\text{w/o}, 32, 64, 256\}$ on segmentation performance. The upper part of Tab. IX shows the results, where "w/o" denotes the absence of memory capacity. As a comparison between w/o and $N = 32$, introducing memory capacity results in a 4-5% increase in mIoU and cIoU, respectively. When $N = 64$, segmentation achieves the highest mIoU. Increasing N to 256 leads to a decrease in mIoU with only marginal improvement in cIoU. Therefore, in subsequent experiments, we set $N = 64$.

2) *Memory Fusion Strategy*: We then compare the segmentation performance across different memory feature fusion \mathcal{F} strategies. Memory feature fusion is adopted to fuse memory features along with the memory capacity N . This process is formulated as $\mathcal{F}(h^\ell) \in \mathbb{R}^{K \times 1 \times D \times H \times W}$. The lower part of Tab. IX presents the results with a fixed memory capacity

TABLE IX

COMPARISON OF MEMORY CAPACITY AND MEMORY FUSION. THE UPPER PART OF THE TABLE COMPARES DIFFERENT MEMORY CAPACITIES, WHERE W/O INDICATES THE ABSENCE OF MEMORY CAPACITY IN THE PROPOSED CLM MODULE. THE LOWER PART EVALUATES THE PERFORMANCE OF VARIOUS MEMORY FUSION METHODS UNDER A FIXED CAPACITY.

Design of CLM module	Learnable Parameter	SIOR-T	
		mIoU	cIoU
<i>Memory Capacity N (Fusion by Conv3D)</i>			
w/o	0	76.56	83.25
32	2.7K	80.77	88.12
64	2.7K	84.25	89.82
256	2.7K	83.88	89.99
<i>Memory Fusion (Capacity = 64)</i>			
Argmax	0	79.24	87.21
Conv2D	2.7K	83.88	89.42
Conv3D	2.7K	84.25	89.82
Attention	532.8K	83.91	88.92
Dual Attention	34.6M	84.20	89.95

TABLE X

COMPARISON OF DIFFERENT PROJECTOR STRATEGIES.

Projector strategy	SIOR-T	
	mIoU	cIoU
Shared	74.65	85.31
Independent	84.25	89.82

of $N = 64$. The Argmax strategy applies an argmax operation over N to reduce it to 1 in a non-learnable manner. Conv2D first reshape h^ℓ into $KD \times N \times H \times W$ and employs a 2D convolution. Conv3D treats N as the depth dimension and employs a 3D convolution. The Attention strategy treats $h^\ell \in \mathbb{R}^{HW \times K \times ND}$ as the key and value, while $\mathcal{I}(m_{\text{init}}^\ell) \in \mathbb{R}^{HW \times K \times D}$ serves as the query. The Dual Attention strategy first uses $\mathcal{I}(m_{\text{init}}^\ell)$ as the key and value and $h^\ell \in \mathbb{R}^{HW \times K \times ND}$ as the query in the first attention step. The roles are then reversed, with h^ℓ serving as the key and value, and $\mathcal{I}(m_{\text{init}}^\ell)$ as the query, as formulated in the Attention strategy. As shown in the lower part of Tab. IX, the Conv3D strategy achieves the optimal balance between performance and parameter efficiency. Comparing the Argmax strategy with others, the learnable fusion of memory capacity N enhances mIoU and cIoU by 2%-4%. Although the Dual Attention strategy achieves the highest cIoU, its introduction of significantly more parameters results in reduced efficiency.

3) *Independent or Shared Projectors*: We next conduct ablation studies on different projector strategies. The independent projector strategy uses separate rough and detail projectors to process features at different scales, whereas the shared projector strategy applies a single projector for all feature scales. Tab. X presents the comparison results, highlighting the superiority of independent projectors over shared ones. The results reveal a 4–5% improvement in mIoU and cIoU on the SIOR-T subset, confirming that decoupling projection across different visual pathways enhances segmentation performance.

4) *Two-stage Training Strategies*: We finally conduct ablation studies to analyze the impact of different training strategies on the performance of multiple tasks, including image captioning (IC), visual question answering (VQA), visual grounding (Grd.), and multi-referring segmentation (Seg.). We compare single-stage and two-stage approaches. A representa-

TABLE XI

COMPARISON OF DIFFERENT TRAINING STRATEGIES IN TERMS OF COMPUTATIONAL COST AND PERFORMANCE ON MULTI-MODAL TASKS.

Training strategy	Cost	IC	VQA	Grd.	Seg.
		CLAIR	Avg.	All.A@0.5	SIOR-T cIoU
Single-stage	1,010	71	73.8	39.5	85.94
Stage1	101	72	74.8	47.4	74.73
+ Stage2	125	77	74.9	49.8	89.95

tive metric is selected for each task to evaluate the results, as shown in Tab. XI. We assess the performance of the models in each stage of the proposed two-stage training strategy, with the training cost measured in A800 GPU hours. For the single-stage training strategy, we randomly select 8,000 samples from VRSBench and combine them with the SIOR-T subset to form the training set, which is trained for 50 epochs. As shown in Tab. XI, the proposed two-stage training strategy achieves superior performance across all tasks while maintaining the highest efficiency. By adjusting the data ratio in multi-task learning, the two-stage training approach effectively mitigates the tug-of-war problem inherent in multi-task optimization for pixel-level MLLMs, leading to improved performance with reduced computational cost.

VI. CONCLUSION

In this paper, we propose GeoPix, a multi-modal large language model (MLLM) for remote sensing that extends the capabilities of previous RS MLLMs from image- and region-level to pixel-level image understanding. We design a class-wise learnable memory module to enhance segmentation accuracy by adaptively extracting and storing class-wise regional geo-context. To facilitate pixel-level RS MLLM training, we constructed GeoPixInstruct by integrating existing datasets and designing a description generation pipeline powered by GPT-4o to produce instance-level descriptions. Moreover, we propose a two-stage training strategy to mitigate the tug-of-war issue in multi-modal, multi-task optimization of pixel-level RS MLLMs. Overall, GeoPix exhibits superior performance on pixel-level tasks while maintaining competitive capabilities at both the image and region levels.

Limitation and Future Work. Given current resource constraints, we are unable to perform manual verification of GeoPixInstruct. Instead, we utilize vision fine-tuning with human feedback to enhance the accuracy of the generated descriptions. In future work, we plan to leverage MLLMs to further improve the quality of generated descriptions and develop an MLLM-driven filtering pipeline to minimize the need for manual verification.
