# More resourceful states improve quantum channel discrimination

Kenji Nakahira

Quantum Information Science Research Center, Quantum ICT Research Institute, Tamagawa University, Machida, Tokyo 194-8610, Japan (Dated: January 17, 2025)

One of the key issues in quantum discrimination problems is understanding the extent of the advantages in discrimination performance when using resource states compared to resourceless states. We show that in any resource theory of states, which may not be convex, the extent to which the maximum average success probability can be improved in quantum channel discrimination problems without using auxiliary systems can be precisely quantified by the robustness measure. Furthermore, we demonstrate that the robustness measure can also quantify the improvement in channel discrimination problems that use auxiliary systems. Using these findings, resources can be fully characterized to achieve higher success probabilities than any state without the given resource in channel discrimination problems.

Discrimination problems are fundamental in considering the operational properties of quantum theory. Among these, quantum channel discrimination stands out as a critical task, focused on the precise identification of quantum channels by transmitting an input state through them and measuring the resulting output states. This capability is essential for a wide range of applications, including quantum communication [1], quantum sensing [2], and quantum cryptography [3]. The ongoing research in this field [4–14] is pivotal in enhancing the accuracy of channel discrimination, thereby significantly boosting the efficiency and security of quantum protocols.

In channel discrimination problems, appropriately selecting the state to input into the channels directly impacts the effectiveness of the discrimination protocol. For example, it is known that using any entangled state as the input state can improve channel discrimination performance compared to using any separable state [15]. While entanglement is a typical resource in quantum information processing, various other types of quantum resources are also explored, such as coherence [16–18], superposition [19], asymmetry[20, 21], magic[22, 23], non-Gaussianity[24-26], non-Markovianity[27, 28], quantum thermodynamics[29, 30], and imaginarity[31, 32]. These resources can sometimes be treated in a unified manner as quantum resource theories. Recently, Takagi et al. [33] have shown that in any convex resource theory, every resource state is useful for some channel discrimination task compared to any resourceless state, called free state. Continuous analysis of resource states leads to the refinement of strategies to achieve optimal performance in various quantum systems and contributes to extensive discussions on the strategic use of quantum resources.

A natural question arises as to how much the performance can be improved in channel discrimination tasks using a given resource state compared to free states. For this problem, the ratio of the maximum average success probability in channel discrimination problems using a given state to that using the best free state has been a focal point of research. In several resource theories (e.g., entanglement [34], steerability [35], coherence [36, 37], and asymmetry [38]), it has been shown that the supremum of this ratio, which we call the discrimination power, can be precisely quantified by a measure known as the (generalized) robustness (see also [33, 39]). However, these results are limited to specific types resource theories and

are difficult to generalize in their current form. It is also well known that in channel discrimination problems, the maximum average success probability can generally be improved by using auxiliary systems (e.g., [40]). Therefore, the discrimination power of channels with auxiliary systems has also been focused. Nevertheless, it is generally difficult to determine the discrimination power compared to the case without auxiliary systems, and it has only been quantified in some special cases [34, 35].

Instead of focusing on discrimination power, a more analytically tractable indicator has been considered: the ratio of the average success probability when the measurement used for discrimination is fixed in subchannel discrimination tasks in convex resource theories for a given state. It has been shown that the supremum of this ratio can be quantified by the robustness measure [33], and this result has been extended to infinite-dimensional systems, nonconvex resource theories, and general probabilistic theories [41-45]. In this paper, we focus on discrimination power, which appears to be a more straightforward indicator from the perspective of channel discrimination problems, limited to finite-dimensional systems.

We address the problem of whether the discrimination power can be quantified by the robustness measure in general resource theories, which is mentioned as an important outstanding open question in Ref. [33]. First, we show that in channel discrimination problems without auxiliary systems for any convex resource theory, the discrimination power of any resource state can be quantified by the robustness. This implies that the robustness measure can be interpreted as the discrimination power, which is an intuitively clear operational value. We also show that this result can be easily extended to nonconvex resource theories. Furthermore, we demonstrate that in channel discrimination problems using auxiliary systems, the discrimination power of any resource state can similarly be quantified by the robustness. This result provides a necessary and sufficient condition for the maximum average success probability of a given resource state to be higher than that of any free state.

Discrimination power — Let us consider the problem of distinguishing a collection of channels  $\{\Lambda_n\}_{n=1}^N$  from system A to system B. The prior probabilities are given by  $\{p_n\}_{n=1}^N$ . When a state  $\rho$  is input into system A and a measurement  $\Pi := {\{\Pi_n\}_{n=1}^N}$  is performed on the output state in system B, the average success probability is given by

$$P_{\mathrm{S}}(\rho,\Pi;\{p_n,\Lambda_n\}) \coloneqq \sum_{n=1}^{N} p_n \operatorname{Tr}[\Pi_n \cdot \Lambda_n(\rho)].$$
(1)

When distinguishing  $\{\Lambda_n\}_{n=1}^N$  with just one use of the channels, any discrimination strategy can be represented using such a pair of  $\rho$  and  $\Pi$ . Thus, the maximum average success probability when  $\rho$  is fixed is given by

$$P_{\mathcal{S}}(\rho; \{p_n, \Lambda_n\}) \coloneqq \max_{\Pi} P_{\mathcal{S}}(\rho, \Pi; \{p_n, \Lambda_n\}).$$

Let  $Den_A$  denote the set of all density matrices of system A. We consider a subset  $\mathbb{F}$  of  $Den_A$ , the elements of which are regarded as free states. For any state  $\rho$  of A, the supremum ratio of the maximum average success probability using  $\rho$  to that using free states is defined as

$$G(\rho, \mathbb{F}) := \sup_{\{p_n, \Lambda_n\}} \frac{P_{\mathcal{S}}(\rho; \{p_n, \Lambda_n\})}{\sup_{\omega \in \mathbb{F}} P_{\mathcal{S}}(\omega; \{p_n, \Lambda_n\})}$$
(2)

and is referred to as the discrimination power of  $\rho$  with respect to  $\mathbb{F}$ . For some  $\mathbb{F}$ , it has been shown that  $G(\rho, \mathbb{F}) = 1 + R_{\mathbb{F}}(\rho)$ holds [34, 36–38], where  $R_{\mathbb{F}}(\rho)$  is the robustness measure, defined as

$$R_{\mathbb{F}}(\rho) \coloneqq \inf \left\{ \lambda \ge 0 \; \middle| \; \frac{\rho + \lambda \tau}{1 + \lambda} \coloneqq \omega \in \mathbb{F}, \; \tau \in \mathsf{Den}_A \right\}. \tag{3}$$

 $R_{\mathbb{F}}(\rho)$  can be interpreted as the least coefficient needed for the mixture of  $\rho$  and a noise state  $\tau$  to result in a free state.  $R_{\mathbb{F}}(\rho)$  is well defined for any  $\rho$  as long as  $\mathbb{F}$  contains at least one positive definite matrix, which we assume in what follows when referring to  $R_{\mathbb{F}}(\rho)$ . We discuss the case in which this assumption is not satisfied in Appendix D.

**Theorem 1** We have that, for any convex subset  $\mathbb{F}$  of  $Den_A$ ,

$$G(\rho, \mathbb{F}) = 1 + R_{\mathbb{F}}(\rho)$$

**Proof** Let  $cl \mathbb{F}$  denote the closure of  $\mathbb{F}$ . Since  $G(\rho, \mathbb{F}) = G(\rho, cl \mathbb{F})$  and  $R_{\mathbb{F}}(\rho) = R_{cl \mathbb{F}}(\rho)$  hold, we assume, without loss of generality, that  $\mathbb{F}$  is closed.

First, we show  $G(\rho, \mathbb{F}) \leq 1 + R_{\mathbb{F}}(\rho)$ . Let  $\lambda^*$  and  $\omega^*$  be the minimizers of Eq. (3). For any collection  $\{p_n, \Lambda_n\}$  of channels  $\Lambda_n$  with prior probabilities  $p_n$  and for any measurement  $\Pi$ , we have

$$P_{S}(\rho, \Pi; \{p_{n}, \Lambda_{n}\}) \leq (1 + \lambda^{\star}) \cdot P_{S}(\omega^{\star}, \Pi; \{p_{n}, \Lambda_{n}\})$$
$$\leq (1 + \lambda^{\star}) \cdot \max_{\omega \in \mathbb{P}} P_{S}(\omega; \{p_{n}, \Lambda_{n}\}), \quad (4)$$

where the first line follows from  $\rho \leq (1 + \lambda^*)\omega^*$ . Dividing both sides by  $\max_{\omega \in \mathbb{F}} P_{\mathcal{S}}(\omega; \{p_n, \Lambda_n\})$  and using  $\lambda^* = R_{\mathbb{F}}(\rho)$ , we obtain  $G(\rho, \mathbb{F}) \leq 1 + R_{\mathbb{F}}(\rho)$ .

Next, we show  $G(\rho, \mathbb{F}) \ge 1 + R_{\mathbb{F}}(\rho)$ . Considering the Lagrange dual problem of the optimization problem in Eq. (3), we find that  $R_{\mathbb{F}}(\rho)$  is the optimal value of the following optimization problem (e.g., [46]):

maximize 
$$\operatorname{Tr}(x\rho) - 1$$
  
subject to  $x \ge 0$ ,  $\operatorname{Tr}(x\omega) \le 1 \ (\forall \omega \in \mathbb{F}).$  (5)

Let  $x^*$  be the optimal solution of this problem, and let  $e := x^*/||x^*||_{\infty}$ . Also, let  $\omega^*$  be  $\omega \in \mathbb{F}$  that maximizes  $\operatorname{Tr}(e\omega)$ . Choose an *N*-level system *B*, where *N* satisfies the condition  $N \ge 1 + \operatorname{Tr}(e\omega^*)^{-1}$ ; then, we have that, for each  $\sigma \in \operatorname{Den}_A$ ,

$$\frac{1 - \operatorname{Tr}(e\sigma)}{N - 1} \le \frac{1}{N - 1} \le \operatorname{Tr}(e\omega^{\star}).$$
(6)

Let  $p_n := 1/N$  and define the channels  $\Lambda_1, \ldots, \Lambda_N$  as

$$\Lambda_{n}(\sigma) = \operatorname{Tr}(e\sigma) |n\rangle \langle n| + \frac{1 - \operatorname{Tr}(e\sigma)}{N - 1} (I_{N} - |n\rangle \langle n|)$$

for each  $\sigma \in \text{Den}_A$ , where  $\{|i\rangle\}_{i=1}^N$  is the computational basis. Since  $\Lambda_n(\sigma) = X^{n-1} \cdot \Lambda_1(\sigma) \cdot X^{1-n}$  holds for the generalized Pauli-X matrix X,  $\{\Lambda_n\}$  is covariant with respect to the cyclic group  $\mathcal{G} := \{X^k(-)X^{-k}\}_{k=1}^N$ . Thus, there exists a measurement  $\Pi^{\text{sym}}$  that satisfies  $P_S(\sigma, \Pi; \{p_n, \Lambda_n\}) = \text{Tr}[\Pi_1^{\text{sym}} \cdot \Lambda_1(\sigma)]$ for any state  $\sigma$  of A and is covariant with respect to  $\mathcal{G}$ , i.e.,  $\Pi_n^{\text{sym}} = X^{n-1}\Pi_1^{\text{sym}}X^{1-n}$ , proved in Appendix B. For such a measurement  $\Pi^{\text{sym}}$ , let  $c := \langle 1|\Pi_1^{\text{sym}}|1\rangle$ ; then, we have

$$P_{S}(\sigma, \Pi; \{p_{n}, \Lambda_{n}\}) = \operatorname{Tr}\left[\Pi_{1}^{\operatorname{sym}} \cdot \Lambda_{1}(\sigma)\right]$$
$$= c \operatorname{Tr}(e\sigma) + (1-c) \frac{1 - \operatorname{Tr}(e\sigma)}{N-1}, \quad (7)$$

where we use  $\operatorname{Tr} \Pi_1^{\operatorname{sym}} = 1$  from  $\sum_{n=1}^N \Pi_n^{\operatorname{sym}} = I_N$ . Therefore, we have that, for each  $\omega \in \mathbb{F}$ ,

$$P_{\mathsf{S}}(\omega,\Pi;\{p_n,\Lambda_n\}) = c \operatorname{Tr}(e\omega) + (1-c) \frac{1-\operatorname{Tr}(e\omega)}{N-1} \leq \operatorname{Tr}(e\omega^{\star}),$$

where the inequality follows from  $\text{Tr}(e\omega) \leq \text{Tr}(e\omega^*)$  and substituted  $\sigma = \omega$  into Eq. (6). Therefore, we obtain  $P_{\text{S}}(\omega; \{p_n, \Lambda_n\}) \leq \text{Tr}(e\omega^*)$ . Also, for a measurement  $\Pi$  satisfying  $c = \langle 1 | \Pi_1^{\text{sym}} | 1 \rangle = 1$ , Eq. (7) gives  $P_{\text{S}}(\rho, \Pi; \{p_n, \Lambda_n\}) =$  $\text{Tr}(e\rho)$ . Thus, we have

$$\frac{P_{\mathrm{S}}(\rho; \{p_n, \Lambda_n\})}{\sup_{\omega \in \mathbb{F}} P_{\mathrm{S}}(\omega; \{p_n, \Lambda_n\})} \geq \frac{\mathrm{Tr}(e\rho)}{\mathrm{Tr}(e\omega^{\star})} = \frac{\mathrm{Tr}(x^{\star}\rho)}{\mathrm{Tr}(x^{\star}\omega^{\star})} \geq \mathrm{Tr}(x^{\star}\rho),$$

where the last inequality follows from  $\operatorname{Tr}(x^*\omega^*) \leq 1$ . From this equation and  $\operatorname{Tr}(x^*\rho) = 1 + R_{\mathbb{F}}(\rho)$ , we obtain  $G(\rho, \mathbb{F}) \geq 1 + R_{\mathbb{F}}(\rho)$ .

From this proof, the supremum  $\sup_{\{p_n,\Lambda_n\}}$  in Eq. (2) can be replaced with the maximum  $\max_{\{p_n,\Lambda_n\}}$ . While Eq. (2) represents the discrimination power for channels, it is immediately clear that a similar equation holds for the discrimination power for subchannels, defined as completely positive maps  $\{\Gamma_n\}$  such that  $\sum_n \Gamma_n$  is a channel. Furthermore, the robustness can be characterized by

$$\sup_{\{p_n,\Lambda_n\}} \sup_{\Pi} \frac{P_{\mathcal{S}}(\rho,\Pi;\{p_n,\Lambda_n\})}{\sup_{\omega\in\mathbb{F}} P_{\mathcal{S}}(\omega,\Pi;\{p_n,\Lambda_n\})} = 1 + R_{\mathbb{F}}(\rho).$$
(8)

Indeed, from the first line of Eq. (4), it is clear that the lefthand side of this equation is less than or equal to the righthand side, while from the definition of  $G(\rho, \mathbb{F})$ , the left-hand side is at least  $G(\rho, \mathbb{F})$ . It is known that a corresponding equation holds for subchannel discrimination (see Theorem 1 in [33]); Eq. (8) implies that it also holds for channel discrimination.

The case of the set of free states being nonconvex — Let  $\cos S$  denote the convex hull of a set S. Then, the following corollary is immediately obtained.

**Corollary 2** We have that, for any subset  $\mathbb{F}$  of  $\mathsf{Den}_A$ ,

$$G(\rho, \mathbb{F}) = G(\rho, \operatorname{co} \mathbb{F}) = 1 + R_{\operatorname{co} \mathbb{F}}(\rho).$$

**Proof** The right-hand equality is clear from Theorem 1. To prove the left-hand equality, it is sufficient to show

$$\sup_{\omega\in\mathbb{F}}P_{\mathrm{S}}(\omega;\{p_n,\Lambda_n\})=\sup_{v\in\mathrm{co}\,\mathbb{F}}P_{\mathrm{S}}(v;\{p_n,\Lambda_n\}).$$

From  $\mathbb{F} \subseteq \operatorname{co} \mathbb{F}$ , the left-hand side is clearly less than or equal to the right-hand side. The left-hand side is also greater than or equal to the right-hand side since any  $v \in \operatorname{co} \mathbb{F}$  can be expressed as a convex combination of some  $\omega_1, \omega_2, \dots \in \mathbb{F}$ , and  $P_{S}(v; \{p_n, \Lambda_n\}) \leq \max_i P_{S}(\omega_i; \{p_n, \Lambda_n\})$  holds.

In this paper, we denote a resource state  $\rho \notin \mathbb{F}$  that satisfies  $G(\rho, \mathbb{F}) = 1$  as a bound resource state. By this definition, a bound resource state can be seen as a resource state that is not useful for channel discrimination. From Corollary 2, it is immediately clear that  $\rho \notin \mathbb{F}$  being a bound resource state is equivalent to  $\rho \in \operatorname{co} \mathbb{F}$ . In particular, there are no bound resource states if and only if  $\mathbb{F}$  is convex and closed.

Extension to discrimination problems using auxiliary systems — In the problem of distinguishing a collection of channels  $\{\Lambda_n\}_{n=1}^N$  from system *A* to system *B*, using an appropriate auxiliary system *C* can improve the average success probability. When the prior probabilities are  $\{p_n\}_{n=1}^N$ , the average success probability when a state  $\rho$  is input into the composite system  $A \otimes C$  and a measurement  $\Pi := \{\Pi_n\}_{n=1}^N$  is performed on the composite system  $B \otimes C$  is given by

$$P_{\mathbf{S}}(\rho, \Pi; \{p_n, \Lambda_n\}) \coloneqq \sum_{n=1}^{N} p_n \operatorname{Tr}[\Pi_n \cdot (\Lambda_n \otimes \operatorname{id}_C)(\rho)] \quad (9)$$

instead of Eq. (1).

Given a state  $\rho \in \text{Den}_{A \otimes C}$  and the set of free states  $\mathbb{F}$  of the composite system  $A \otimes C$ , let  $G_C(\rho, \mathbb{F})$  denote the discrimination power  $G(\rho, \mathbb{F})$  defined by Eq. (2) using the average success probability in Eq. (9). Let us consider determining this discrimination power. Note that when *C* is a quantum 1level system (i.e., no auxiliary system),  $G_C(\rho, \mathbb{F})$  and  $G(\rho, \mathbb{F})$ are clearly equal. For a set *S* of some states of the composite system  $A \otimes C$ , if for any  $\omega \in S$  and any channel  $\mathcal{E}$  on *C*, the state ( $\mathrm{id}_A \otimes \mathcal{E}$ )( $\omega$ ) is in *S*, then we say that *S* preserves operations on *C*. If  $\mathbb{F}$  preserves operations on *C*, then it means that applying any local channel to system *C* does not turn a free state into a resource state.

**Theorem 3** If a convex subset  $\mathbb{F}$  of  $\mathsf{Den}_{A\otimes C}$  preserves operations on *C*, then we have

$$G_C(\rho, \mathbb{F}) = 1 + R_{\mathbb{F}}(\rho)$$

**Proof**  $G_C(\rho, \mathbb{F})$  can be considered the discrimination power when a collection of channels from  $A \otimes C$  to  $B \otimes C$  is limited to those of the form  $\{\Lambda_n \otimes \operatorname{id}_C\}_{n=1}^N$ . Therefore,  $G_C(\rho, \mathbb{F})$  cannot be greater than  $G(\rho, \mathbb{F})$ , and thus  $G_C(\rho, \mathbb{F}) \leq G(\rho, \mathbb{F}) = 1 + R_{\mathbb{F}}(\rho)$ holds from Theorem 1. It remains to show that  $G_C(\rho, \mathbb{F}) \geq$  $1 + R_{\mathbb{F}}(\rho)$ . Here, we present an outline; the full proof is given in Appendix C.

Let  $x^*$  be the optimal solution of Problem (5). For a nonnormalized maximally entangled state  $|\Phi\rangle := \sum_{n=1}^{N_C} |n\rangle \otimes |n\rangle$ , where  $N_C$  is the level of *C*, we can choose a positive real number *c* and subchannels  $\{\tilde{\Lambda}_n\}_{n=1}^N$  that satisfy

$$\langle \Phi | (\tilde{\Lambda}_1 \otimes \mathsf{id}_C)(\rho) | \Phi \rangle = c \operatorname{Tr}(x^* \rho), \quad \forall \rho \in \mathsf{Den}_{A \otimes C}.$$
 (10)

We consider the collection of channels  $\{\Lambda_{i,q,r}\}_{(i,q,r)=(1,1,1)}^{(N,N_C,N_C)}$  defined by

$$\Lambda_{i,q,r}(-) := \sum_{n=0}^{N-1} |n+i\rangle \langle n+i| \otimes X^{q-1} Z^{r-1} \tilde{\Lambda}_{n+1}(-) Z^{1-r} X^{1-q},$$

where  $|N + 1\rangle := |1\rangle, ..., |2N - 1\rangle := |N - 1\rangle$ , and *X* (resp. *Z*) is the generalized Pauli-*X* (resp. Pauli-*Z*) matrix. Then, it can be seen that this collection is covariant with respect to a certain group, and for equal prior probabilities  $\{p_{i,q,r} := 1/(NN_C^2)\}_{(i,q,r)=(1,1,1)}^{(N,N_C,N_C)}$ ,

$$N_C P_S(\rho; \{p_{i,q,r}, \Lambda_{i,q,r}\}) \ge \langle \Phi | (\Lambda_1 \otimes \mathsf{id}_C)(\rho) | \Phi \rangle$$

holds. It can also be shown that for any positive real number  $\varepsilon$  and any free state  $\omega$ , there exists a channel  $\Gamma$  satisfying

$$N_{C}P_{S}(\omega; \{p_{i,q,r}, \Lambda_{i,q,r}\}) \leq \langle \Phi | (\tilde{\Lambda}_{1} \otimes \Gamma)(\omega) | \Phi \rangle + c\varepsilon$$
$$\leq \sup_{\omega' \in \mathbb{F}} \langle \Phi | (\tilde{\Lambda}_{1} \otimes \mathsf{id}_{C})(\omega') | \Phi \rangle + c\varepsilon,$$

where the second line follows from  $(id_A \otimes \Gamma)(\omega)$  being a free state. Therefore, we have that, from Eq. (10),

$$G_C(\rho, \mathbb{F}) \ge \frac{c \operatorname{Tr}(x^* \rho)}{c \sup_{\omega' \in \mathbb{F}} \operatorname{Tr}(x^* \omega') + c\varepsilon} \ge \frac{1 + R_{\mathbb{F}}(\rho)}{1 + \varepsilon}.$$

Considering the limit as  $\varepsilon \to 0$ , we obtain  $G_C(\rho, \mathbb{F}) \ge 1 + R_{\mathbb{F}}(\rho)$ .

We provide some examples of sets that preserve operations on *C*. An example is a set that is invariant under local operations and classical communication (LOCC). One such example is the set of all  $\omega \in \text{Den}_{A\otimes C}$  satisfying  $\mu(\omega) \leq c$ , where *c* is a constant and  $\mu$  is an entanglement measure that does not increase under LOCC, such as the Schmidt number [47], the entanglement of formation [48], the logarithmic negativity [49], and the concurrence [50]. The set of all separable states can be considered a special case of this. Other examples include the set of unsteerable states (from *A* to *C* or *C* to *A*) [51] and the set of Bell local states [52]. In Ref. [34], it is shown that for the set,  $S_k$ , of states with Schmidt number at most *k*,  $[1 + R_{S_k}(\rho)]/k$  is a lower bound for  $G_C(\rho, S_k)$ . In contrast, Theorem 3 shows that  $G_C(\rho, S_k)$  is exactly  $1 + R_{S_k}(\rho)$ . Additionally, Ref. [35] defines a different robustness measure

FIG. 1. The robustness of  $\rho \in \text{Den}_{A\otimes C}$  with respect to (a) co  $\mathbb{F}$  and (b) co  $\mathbb{F}_C$ .  $R_{co \mathbb{F}}(\rho) \ge R_{co \mathbb{F}_C}(\rho)$  holds from  $\mathbb{F} \subseteq \mathbb{F}_C$ . From Corollaries 2 and 4, these values respectively quantify the discrimination power  $G(\rho, \mathbb{F})$  and  $G_C(\rho, \mathbb{F})$ . The gray areas, co  $\mathbb{F} \setminus \mathbb{F}$  and co  $\mathbb{F}_C \setminus \mathbb{F}$ , represent the sets of bound resource states in the sense of *G* and  $G_C$ , respectively. Note that  $R_{co \mathbb{F}}(\rho) = R_{co \mathbb{F}_C}(\rho)$ , i.e.,  $G(\rho, \mathbb{F}) = G_C(\rho, \mathbb{F})$ , holds for each  $\rho \in \text{Den}_{A\otimes C}$  if and only if co  $\mathbb{F} = \text{co } \mathbb{F}_C$  holds.

for steerability (where  $\mathbb{F}$  is the set of unsteerable states) and shows that it can quantify the discrimination power in subchannel discrimination problems. Theorem 3 implies a more straightforward quantification.

Given a subset  $\mathbb{F}$  of  $\text{Den}_{A\otimes C}$ , let  $\mathbb{F}_C$  denote the set of all states of the form  $(\text{id}_A \otimes \mathcal{E})(\omega)$ , where  $\omega$  is in  $\mathbb{F}$  and  $\mathcal{E}$  is a channel on *C*. Then, the following corollary is obtained from Theorem 3.

**Corollary 4** We have that, for any subset  $\mathbb{F}$  of  $Den_{A\otimes C}$ ,

$$G_C(\rho, \mathbb{F}) = G_C(\rho, \mathbb{F}_C) = 1 + R_{\operatorname{co}\mathbb{F}_C}(\rho).$$
(11)

**Proof** Using the same method as in Corollary 2, we find  $G_C(\rho, \mathbb{F}_C) = G_C(\rho, \mathbb{O} \mathbb{F}_C)$ . Each  $v \in \operatorname{co} \mathbb{F}_C$  can be expressed in the form  $\sum_i q_i (\operatorname{id}_A \otimes \mathcal{E}_i)(\omega_i)$ , where  $\omega_1, \omega_2, \ldots$  are in  $\mathbb{F}$ ,  $\mathcal{E}_1, \mathcal{E}_2, \ldots$  are channels on *C*, and  $\{q_i\}$  is a probability distribution. Therefore, for any channel  $\mathcal{E}'$  on *C*,  $(\operatorname{id}_A \otimes \mathcal{E}')(v) = \sum_i q_i(\operatorname{id}_A \otimes \mathcal{E}' \circ \mathcal{E}_i)(\omega_i) \in \operatorname{co} \mathbb{F}_C$ , and thus  $\operatorname{co} \mathbb{F}_C$  preserves operations on *C*. From Theorem 3, the right-hand equality in Eq. (11) holds. To show the left-hand equality in Eq. (11), it is sufficient to show that

$$\sup_{\omega \in \mathbb{F}} P_{\mathcal{S}}(\omega; \{p_n, \Lambda_n\}) = \sup_{v \in \mathbb{F}_C} P_{\mathcal{S}}(v; \{p_n, \Lambda_n\}).$$

From  $\mathbb{F} \subseteq \mathbb{F}_C$ , the left-hand side is clearly less than or equal to the right-hand side. The left-hand side is also greater than or equal to the right-hand side since for each  $v \in \mathbb{F}_C$  expressed as  $(\mathrm{id}_A \otimes \mathcal{E})(\omega)$  (where  $\omega$  is in  $\mathbb{F}$  and  $\mathcal{E}$  is a channel on *C*), we have that, for any measurement  $\Pi$ ,

$$P_{S}(v, \Pi; \{p_{n}, \Lambda_{n}\}) = \sum_{n=1}^{N} p_{n} \operatorname{Tr}[\Pi_{n} \cdot (\Lambda_{n} \otimes \operatorname{id}_{C})[(\operatorname{id}_{A} \otimes \mathcal{E})(\omega)]]$$
$$= \sum_{n=1}^{N} p_{n} \operatorname{Tr}[(\operatorname{id}_{B} \otimes \mathcal{E})^{\dagger}(\Pi_{n}) \cdot (\Lambda_{n} \otimes \operatorname{id}_{C})(\omega)]$$
$$\leq P_{S}(\omega; \{p_{n}, \Lambda_{n}\}),$$

where  $\dagger$  denotes the adjoint. The inequality follows from  $\{(id_B \otimes \mathcal{E})^{\dagger}(\Pi_n)\}_{n=1}^N$  being a measurement.

Equation (11) allows the discrimination power using auxiliary systems to be formulated in terms of the robustness. This corollary also shows that  $\rho \notin \mathbb{F}$  is a bound resource state in the sense of  $G_C$ , i.e.,  $G_C(\rho, \mathbb{F}) = 1$ , if and only if  $\rho$  is in  $\operatorname{co} \mathbb{F}_C$ . Furthermore, Corollaries 2 and 4 give  $G_C(\rho, \mathbb{F}) = 1 + R_{\operatorname{co} \mathbb{F}_C}(\rho) = G(\rho, \mathbb{F}_C)$ . Figure 1 schematically represents  $R_{\operatorname{co} \mathbb{F}_C}(\rho)$  and  $R_{\operatorname{co} \mathbb{F}_C}(\rho)$ .

*Conclusion* — In this study, we have quantified the discrimination power in quantum channel discrimination problems for any resource theory of states. First, we have quantified the discrimination power of any resource state using the robustness measure in channel discrimination problems without auxiliary systems. This means that the robustness can be fully characterized as a value that can be interpreted operationally as discrimination power of channels. Next, we have shown that in channel discrimination problems using an auxiliary system *C*, the discrimination power can similarly be expressed using the robustness measure with respect to the set co  $\mathbb{F}_C$ . This result is expected to be useful in analyzing the discrimination power in channel discrimination problems involving auxiliary systems.

In our study, we have considered a single-shot channel discrimination strategy that maximizes the average success probability. Future developments of this research could involve considering other optimization criteria, such as an unambiguous criterion or a minimax criterion, or multi-shot strategies to clarify the measures representing discrimination power. Clarifying such measures would deepen our understanding of the relationship between quantum channel discrimination problems and quantum resource theories, promoting further theoretical advancements.

We thank for O. Hirota, M. Sohma, T. S. Usuda, and K. Kato for insightful discussions. This work was supported by the Air Force Office of Scientific Research under award number FA2386-22-1-4056.

# **Appendix A: Preliminaries**

For each quantum system A, let  $N_A$  be the level of A. The set of all positive semidefinite matrices of system A is denoted by  $\mathsf{Pos}_A$ , where square matrices of order  $N_A$  are referred to as square matrices of A. When two Hermitian matrices X and Y of A satisfy  $X - Y \in \mathsf{Pos}_A$ , we write  $X \ge Y$  or  $Y \le X$ . In particular,  $X \ge 0$  (where 0 is the zero matrix) is equivalent to  $X \in \mathsf{Pos}_A$ . The sets of all completely positive (CP) maps, all channels, i.e., trace-preserving CP maps, and all trace-nonicreasing CP maps (called TNI-CP maps) from system A to system B are denoted by  $\mathsf{CP}_{A\to B}$ ,  $\mathsf{Chn}_{A\to B}$ , and  $\mathsf{TNICP}_{A\to B}$ , respectively. A map from A to A is called a map on A, and the identity channel on A is denoted by  $\mathsf{id}_A$ . CP maps { $\Lambda_n \in \mathsf{CP}_{A\to B}$ }<sup>N</sup><sub>n=1</sub> (where N is a natural number) that satisfy  $\sum_{n=1}^{N} \Lambda_n \in \mathsf{Chn}_{A\to B}$  are called subchannels. The convex hull of a set S is denoted by  $\mathsf{co} S$ , and the closure by  $\mathsf{cl} S$ . The composition of maps is denoted by  $\circ$ , and the

The convex hull of a set *S* is denoted by co *S*, and the closure by cl *S*. The composition of maps is denoted by  $\circ$ , and the transpose by <sup>T</sup>. The identity matrix of order *N* is denoted by  $I_N$ . A map *f* is often written as f(-). For example,  $\text{Tr}(e \cdot -)$  with  $e \in \text{Pos}_A$  refers to the map  $\text{Pos}_A \ni x \mapsto \text{Tr}(ex) \in \mathbb{R}_{\geq 0}$ , where  $\mathbb{R}_{\geq 0}$  is the set of all non-negative real numbers, and in particular,  $\text{Tr}(I_{N_A} \cdot -)$  can be written as Tr -.

The computational basis of each system A is denoted by  $\{|n\}_{n=1}^{N_A}$ . The unitary matrix X of order  $N_A$  defined by  $X|n\rangle = |n+1\rangle$ ( $\forall n \in \{1, ..., N_A - 1\}$ ) and  $X|N_A\rangle = |1\rangle$  is called the *generalized Pauli-X matrix*. The unitary matrix Z of order  $N_A$  defined by  $Z|n\rangle = \exp[2\pi n \sqrt{-1}/N_A] |n\rangle$  ( $\forall n \in \{1, ..., N_A\}$ ) is called the *generalized Pauli-X matrix*.

Let  $\Phi_A$  be the non-normalized maximally entangled state of the composite system  $A \otimes A$  denoted by

$$\Phi_A \coloneqq |\Phi\rangle \langle \Phi| \in \mathsf{Pos}_{A \otimes A}, \quad |\Phi\rangle \coloneqq \sum_{n=1}^{N_A} |n\rangle \otimes |n\rangle.$$

We have that, for each  $\rho, \sigma \in \mathsf{Pos}_A$ ,

$$\operatorname{Tr}\left[\Phi_{A} \cdot (\rho \otimes \sigma)\right] = \operatorname{Tr}(\sigma^{\mathsf{T}} \rho). \tag{A1}$$

Also, we have that, for each  $\rho, \sigma \in \mathsf{Pos}_{A \otimes C}$ ,

$$\operatorname{Tr}\left[\Phi_{C} \cdot \left[\left[\operatorname{Tr}(\sigma \cdot -) \otimes \mathsf{id}_{C}\right] \circ \left(\mathsf{id}_{A} \otimes \Phi_{C}\right) \otimes \mathsf{id}_{C}\right](\rho)\right] = \operatorname{Tr}(\sigma\rho) \tag{A2}$$

since, for each  $\rho_1 \in \mathsf{Pos}_A$  and  $\rho_2 \in \mathsf{Pos}_C$ ,

$$\operatorname{Tr} \left[ \Phi_{C} \cdot \left[ [\operatorname{Tr}(\sigma \cdot -) \otimes \operatorname{id}_{C}] \circ (\operatorname{id}_{A} \otimes \Phi_{C}) \otimes \operatorname{id}_{C}](\rho_{1} \otimes \rho_{2}) \right] = \operatorname{Tr} \left[ \rho_{2}^{\mathsf{T}} \cdot \left[ \operatorname{Tr}[\sigma \cdot (\rho_{1} \otimes -)] \otimes \operatorname{id}_{C}](\Phi_{C}) \right] \right]$$
$$= \operatorname{Tr} \left[ (\sigma' \otimes \rho_{2}^{\mathsf{T}}) \cdot \Phi_{C} \right]$$
$$= \operatorname{Tr}(\sigma' \rho_{2})$$
$$= \operatorname{Tr}[\sigma(\rho_{1} \otimes \rho_{2})]$$

holds, where  $\sigma' := \text{Tr}_A[\sigma(\rho_1 \otimes I_{N_C})]$  and the first and third lines follow from Eq. (A1).

## **Appendix B: Group covariant measurements**

For any system *B* and any finite group *G*, let us consider a collection of unitary matrices  $\{U_g\}_{g\in G}$  of order  $N_B$  satisfying  $U_e = I_{N_B}$  for the identity element *e* of *G*, and  $\mathcal{U}_g \circ \mathcal{U}_h = \mathcal{U}_{gh}$  for all  $g, h \in G$ , where  $\mathcal{U}_g$  is  $U_g(-)\mathcal{U}_g^{-1} \in Chn_{B\to B}$ , i.e., the map  $Den_B \ni \rho \mapsto U_g \rho \mathcal{U}_g^{-1} \in Den_B$ . Let  $\mathcal{G} \coloneqq \{\mathcal{U}_g\}_{g\in G}$ ; then,  $\mathcal{G}$  can be seen as an action of *G* on  $Den_B$ .  $\mathcal{G}$  itself is also a group with composition  $\circ$  as the operation and  $\mathcal{U}_e = id_B$  as its identity element.

Let |G| denote the number of elements in G, and consider a collection of channels  $\{\Lambda_g\}_{g\in G}$  from A to B that satisfies  $\Lambda_{gh} = \mathcal{U}_g \circ \Lambda_h$  for all  $g, h \in G$ . Also, let us consider the equal prior probabilities  $\{p_g := |G|^{-1}\}_{g\in G}$ ; then, the collection  $\{p_g, \Lambda_g\}_{g\in G}$  of channels  $\Lambda_g$  with prior probabilities  $p_g$  (or simply the collection  $\{\Lambda_g\}$ ) is called  $\mathcal{G}$ -covariant. Additionally, a measurement  $\Pi := \{\Pi_g\}_{g\in G}$  on system B is called  $\mathcal{G}$ -covariant if it satisfies  $\Pi_{gh} = \mathcal{U}_g(\Pi_h)$  for all  $g, h \in G$ .

**Example 1** In the proof of Theorem 1, we consider a collection of channels  $\{\Lambda_n\}_{n=1}^N$  that satisfies  $\Lambda_n(\sigma) = X^{n-1} \cdot \Lambda_1(\sigma) \cdot X^{1-n}$ . For an integer *n*, let

$$\llbracket n \rrbracket_N := \begin{cases} n, & 1 \le n \le N, \\ \llbracket n - N \rrbracket_N, & n > N, \\ \llbracket n + N \rrbracket_N, & n < 1, \end{cases}$$
(B1)

i.e.,  $[[n]]_N$  is  $n' \in \{1, 2, ..., N\}$  such that n - n' is divisible by N. Consider the cyclic group  $G := \{1, 2, ..., N\}$ , where the product of  $m, n \in G$  is  $[[m + n]]_N$ , and the identity element of G is N. Let  $\mathcal{G} := \{\mathcal{U}_k := X^k(-)X^{-k}\}_{k \in G}$ ; then,  $\{\Lambda_n\}_{n=1}^N$  is  $\mathcal{G}$ -covariant since  $\Lambda_{[[m+n]]_N} = \mathcal{U}_m \circ \Lambda_n$  holds for all  $m, n \in G$ . Note that  $\mathcal{U}_N = id_B$  holds from  $X^N = I_N$ .

The following lemma holds.

**Lemma 5** For any two systems *A* and *B*, consider a *G*-covariant collection  $\{p_g, \Lambda_g\}_{g \in G}$  of channels  $\Lambda_g$  from *A* to *B* with prior probabilities  $p_g$ . For any measurement  $\Pi := {\{\Pi_g\}_{g \in G} \text{ on system } B$ , let us define the measurement  $\Pi^{\text{sym}} := {\{\Pi_g\}_{g \in G} \text{ as}}$ 

$$\Pi_g^{\text{sym}} \coloneqq \frac{1}{|G|} \sum_{h \in G} \mathcal{U}_h(\Pi_{h^{-1}g}),$$

where  $h^{-1}$  is the inverse of  $h \in G$ . Then,  $\Pi^{\text{sym}}$  is *G*-covariant, and we have that, for any state  $\sigma$  of *A*,

$$P_{\mathcal{S}}(\sigma,\Pi;\{p_g,\Lambda_g\}) = P_{\mathcal{S}}(\sigma,\Pi^{\text{sym}};\{p_g,\Lambda_g\}) = \text{Tr}\left[\Pi^{\text{sym}}_{g'}\cdot\Lambda_{g'}(\sigma)\right], \quad \forall g'\in G.$$
(B2)

**Proof** It is clear that  $\Pi^{sym}$  is a measurement since

$$\sum_{g \in G} \Pi_g^{\text{sym}} = \frac{1}{|G|} \sum_{g \in G} \sum_{h \in G} \mathcal{U}_h(\Pi_{h^{-1}g}) = \frac{1}{|G|} \sum_{h \in G} \mathcal{U}_h\left(\sum_{g \in G} \Pi_{h^{-1}g}\right) = \frac{1}{|G|} \sum_{h \in G} \mathcal{U}_h(I_{N_B}) = I_{N_B}$$

and  $\Pi_g^{\text{sym}} \ge 0$  ( $\forall g \in G$ ) hold. Also, we have that, for each  $g, h \in G$ ,

$$\Pi_{gh}^{\text{sym}} = \frac{1}{|G|} \sum_{k \in G} \mathcal{U}_k(\Pi_{k^{-1}gh}) = \frac{1}{|G|} \sum_{k' \in G} \mathcal{U}_{gk'}(\Pi_{k'^{-1}h}) = \mathcal{U}_g\left[\frac{1}{|G|} \sum_{k' \in G} \mathcal{U}_{k'}(\Pi_{k'^{-1}h})\right] = \mathcal{U}_g(\Pi_h^{\text{sym}}),$$

where  $k' := g^{-1}k$ . Thus,  $\Pi^{\text{sym}}$  is *G*-covariant. We have that, for any  $\sigma \in \text{Den}_A$  and  $g' \in G$ ,

$$\operatorname{Tr}\left[\Pi_{g'}^{\operatorname{sym}} \cdot \Lambda_{g'}(\sigma)\right] = \frac{1}{|G|} \sum_{h \in G} \operatorname{Tr}[\mathcal{U}_{h}(\Pi_{h^{-1}g'}) \cdot \Lambda_{g'}(\sigma)]$$
$$= \frac{1}{|G|} \sum_{h \in G} \operatorname{Tr}[\Pi_{h^{-1}g'} \cdot \mathcal{U}_{h^{-1}}[\Lambda_{g'}(\sigma)]]$$
$$= \frac{1}{|G|} \sum_{h \in G} \operatorname{Tr}[\Pi_{h^{-1}g'} \cdot \Lambda_{h^{-1}g'}(\sigma)]$$
$$= P_{S}(\sigma, \Pi; \{p_{g}, \Lambda_{g}\}),$$
(B3)

where the second line follows from  $\text{Tr}[\mathcal{U}_h(x) \cdot y] = \text{Tr}[x \cdot \mathcal{U}_{h^{-1}}(y)]$  for any  $x, y \in \text{Pos}_B$ . Therefore, we obtain

$$P_{\mathcal{S}}(\sigma, \Pi^{\text{sym}}; \{p_g, \Lambda_g\}) = \frac{1}{|G|} \sum_{g' \in G} \operatorname{Tr} \left[ \Pi^{\text{sym}}_{g'} \cdot \Lambda_{g'}(\sigma) \right] = \frac{1}{|G|} \sum_{g' \in G} P_{\mathcal{S}}(\sigma, \Pi; \{p_g, \Lambda_g\}) = P_{\mathcal{S}}(\sigma, \Pi; \{p_g, \Lambda_g\}). \tag{B4}$$

Equations (B3) and (B4) yield Eq. (B2).

# Appendix C: Proof of Theorem 3

After giving two lemmas, we will prove Theorem 3. Let us consider two systems *A* and *C* and a subset *S* of  $\text{Den}_{A\otimes C}$ . If for any  $\omega \in S$  and any TNI-CP map  $\mathcal{E}$  on *C*, the non-normalized state  $\upsilon := (\text{id}_A \otimes \mathcal{E})\omega$ , once normalized, is in *S* or  $\upsilon = 0$ , then we say that *S* preserves probabilistic transformations on *C*.

**Lemma 6** Arbitrarily choose two systems A and C and a positive real number  $\varepsilon$ . If the set of free states  $\mathbb{F}$  of the composite system  $A \otimes C$  is convex and preserves operations on C, then there exist a natural number N and a collection of subchannels  $\{\tilde{\Lambda}_n\}_{n=1}^N$  from A to C such that

$$\frac{\operatorname{Tr}\left[\Phi_{C}\cdot(\tilde{\Lambda}_{1}\otimes \mathsf{id}_{C})(\rho)\right]}{\sup_{\omega\in\mathbb{F}}\sum_{n=1}^{N}\operatorname{Tr}\left[\Phi_{C}\cdot(\tilde{\Lambda}_{n}\otimes\tilde{\Gamma}_{n})(\omega)\right]} \geq \frac{1+R_{\mathbb{F}}(\rho)}{1+\varepsilon}$$
(C1)

holds for any subchannels  $\{\tilde{\Gamma}_n\}_{n=1}^N$  on *C*. In particular, if  $\mathbb{F}$  preserves probabilistic transformations on *C*, then the same holds for  $\varepsilon = 0$ .

**Proof** First, let us consider the case in which  $\mathbb{F}$  preserves operations on *C*. Let  $x^*$  be the optimal solution of Problem (5). Let  $\omega^*$  be  $\omega \in cl \mathbb{F}$  that maximizes  $Tr(x^*\omega)$ . Also, let

$$e := \frac{x^{\star}}{\|\operatorname{Tr}_{C} x^{\star}\|_{\infty}},$$
  

$$\tilde{e} := [\operatorname{Tr}(e \cdot -) \otimes \operatorname{id}_{C}] \circ (\operatorname{id}_{A} \otimes \Phi_{C}),$$
  

$$a := (\operatorname{Tr} -) - \operatorname{Tr}[\tilde{e}(-)]$$

and let  $\tau$  be any state of *C*. Note that since  $\tilde{e}$  is a TNI-CP map, so is *a*. Clearly,  $\text{Tr}(e\omega) \leq \text{Tr}(e\omega^*)$  holds for any  $\omega \in \mathbb{F}$ . Let  $\varepsilon' \coloneqq \varepsilon/||\text{Tr}_C x^*||_{\infty}$ , and choose a natural number *N* such that

$$\frac{1}{N-1}\operatorname{Tr}[\Phi_C \cdot (\tau \circ a \otimes \operatorname{id}_C)(\sigma)] \le \operatorname{Tr}(e\sigma) + \varepsilon', \qquad \forall \sigma \in \operatorname{Den}_{A \otimes C}$$
(C2)

holds. Since the right-hand side is positive, such N exists. Note that since  $\operatorname{Tr}[\Phi_C \cdot (\tau \circ a \otimes \operatorname{id}_C)(\sigma)] \leq 1$  and  $\operatorname{Tr}(e\sigma) \geq 0$  hold, a stricter condition  $\frac{1}{N-1} \leq \varepsilon'$  can be used to choose N. Define  $\{\tilde{\Lambda}_n\}_{n=1}^N$  as

$$\tilde{\Lambda}_n := \begin{cases} \tilde{e}, & n = 1, \\ \\ \frac{1}{N-1}(\tau \circ a), & n \geq 2; \end{cases}$$

then, since  $\sum_{n=1}^{N} \operatorname{Tr}[\tilde{\Lambda}_{n}(-)] = \operatorname{Tr}[\tilde{e}(-)] + a = \operatorname{Tr} - \text{holds}, \sum_{n=1}^{N} \tilde{\Lambda}_{n}$  is a channel, and thus  $\{\tilde{\Lambda}_{n}\}_{n=1}^{N}$  are subchannels. We have that, for any  $\sigma \in \operatorname{Den}_{A \otimes C}$  and any CP map  $\mathcal{E}$  on C,

$$\operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{1} \otimes \mathcal{E})(\sigma)\right] = \operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{e} \otimes \mathcal{E})(\sigma)\right]$$
$$= \operatorname{Tr}\left[\Phi_{C} \cdot \left[\left[\operatorname{Tr}(e \cdot -) \otimes \operatorname{id}_{C}\right] \circ (\operatorname{id}_{A} \otimes \Phi_{C}) \otimes \operatorname{id}_{C}\right]\left[(\operatorname{id}_{A} \otimes \mathcal{E})(\sigma)\right]\right]$$
$$= \operatorname{Tr}\left[e \cdot (\operatorname{id}_{A} \otimes \mathcal{E})(\sigma)\right], \tag{C3}$$

where the last line follows from Eq. (A2). Thus, the numerator of the left-hand side of Eq. (C1) is

$$\operatorname{Tr}\left[\Phi_{C}\cdot(\tilde{\Lambda}_{1}\otimes \mathsf{id}_{C})(\rho)\right] = \operatorname{Tr}(e\rho). \tag{C4}$$

Also, the denominator of the left-hand side of Eq. (C1) is at most  $Tr(e\omega^*) + \varepsilon'$ . Indeed, we have that, for any  $\omega \in \mathbb{F}$ ,

$$\sum_{n=1}^{N} \operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{n} \otimes \tilde{\Gamma}_{n})(\omega)\right] = \operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{1} \otimes \tilde{\Gamma}_{1})(\omega)\right] + \frac{1}{N-1} \operatorname{Tr}\left[\Phi_{C} \cdot (\tau \circ a \otimes \tilde{\Gamma}_{0})(\omega)\right]$$
$$= \operatorname{Tr}\left[e \cdot (\operatorname{id}_{A} \otimes \tilde{\Gamma}_{1})(\omega)\right] + \frac{1}{N-1} \operatorname{Tr}\left[\Phi_{C} \cdot (\tau \circ a \otimes \operatorname{id}_{C})\left[(\operatorname{id}_{A} \otimes \tilde{\Gamma}_{0})(\omega)\right]\right]$$
$$\leq \operatorname{Tr}\left[e \cdot (\operatorname{id}_{A} \otimes \tilde{\Gamma}_{1})(\omega)\right] + \operatorname{Tr}\left[e \cdot (\operatorname{id}_{A} \otimes \tilde{\Gamma}_{0})(\omega)\right] + \varepsilon'$$
$$= \operatorname{Tr}\left[e \cdot \left[\operatorname{id}_{A} \otimes (\tilde{\Gamma}_{1} + \tilde{\Gamma}_{0})\right](\omega)\right] + \varepsilon'$$
$$\leq \operatorname{Tr}(e\omega^{*}) + \varepsilon', \tag{C5}$$

where  $\tilde{\Gamma}_0 := \sum_{j=2}^N \tilde{\Gamma}_n$ . The second line follows from Eq. (C3) with  $\sigma$  substituted by  $\omega$  and  $\mathcal{E}$  substituted by  $\tilde{\Gamma}_1$ . The third line follows from Eq. (C2), and the last line follows from  $\left[ id_A \otimes (\tilde{\Gamma}_1 + \tilde{\Gamma}_0) \right](\omega) \in \mathbb{F}$ , derived from the fact that  $\mathbb{F}$  preserves operations on *C* and  $\tilde{\Gamma}_1 + \tilde{\Gamma}_0$  is a channel. Therefore, from Eqs. (C4) and (C5), we obtain

$$\frac{\operatorname{Tr}\left[\Phi_{C}\cdot(\tilde{\Lambda}_{1}\otimes \operatorname{id}_{C})(\rho)\right]}{\sup_{\omega\in\mathbb{F}}\sum_{n=1}^{N}\operatorname{Tr}\left[\Phi_{C}\cdot(\tilde{\Lambda}_{n}\otimes\tilde{\Gamma}_{n})(\omega)\right]} \geq \frac{\operatorname{Tr}(e\rho)}{\operatorname{Tr}(e\omega^{\star})+\varepsilon'} = \frac{\operatorname{Tr}(x^{\star}\rho)}{\operatorname{Tr}(x^{\star}\omega^{\star})+\varepsilon} \geq \frac{1+R_{\mathbb{F}}(\rho)}{1+\varepsilon},\tag{C6}$$

where the last inequality follows from  $\text{Tr}(x^*\rho) = 1 + R_{\mathbb{F}}(\rho)$  and  $\text{Tr}(x^*\omega^*) \le 1$ .

Next, let us consider the case in which  $\mathbb{F}$  preserves probabilistic transformations on *C*. This is similar to the case in which  $\mathbb{F}$  preserves operations on *C*, but instead of Eq. (C2), we choose *N* such that

$$\frac{1}{N-1}\operatorname{Tr}[\Phi_C \cdot (\tau \circ a \otimes \operatorname{id}_C)(\omega)] \le \operatorname{Tr}(e\omega^*), \qquad \forall \omega \in \mathbb{F}$$
(C7)

holds. Note that since  $\text{Tr}[\Phi_C \cdot (\tau \circ a \otimes \text{id}_C)(\omega)] \leq 1$  holds, a stricter condition  $\frac{1}{N-1} \leq \text{Tr}(e\omega^*)$  can be used to choose N. We have

$$\sum_{n=1}^{N} \operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{n} \otimes \tilde{\Gamma}_{n})(\omega)\right] = \operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{1} \otimes \tilde{\Gamma}_{1})(\omega)\right] + \frac{1}{N-1} \operatorname{Tr}\left[\Phi_{C} \cdot (\tau \circ a \otimes \tilde{\Gamma}_{0})(\omega)\right]$$
$$= \operatorname{Tr}\left[e \cdot (\operatorname{id}_{A} \otimes \tilde{\Gamma}_{1})(\omega)\right] + \frac{1}{N-1} \operatorname{Tr}\left[\Phi_{C} \cdot (\tau \circ a \otimes \operatorname{id}_{C})\left[(\operatorname{id}_{A} \otimes \tilde{\Gamma}_{0})(\omega)\right]\right]$$
$$= \alpha \operatorname{Tr}(e\omega') + \frac{1-\alpha}{N-1} \operatorname{Tr}\left[\Phi_{C} \cdot (\tau \circ a \otimes \operatorname{id}_{C})(\omega'')\right]$$
$$\leq \alpha \operatorname{Tr}(e\omega^{\star}) + (1-\alpha) \operatorname{Tr}(e\omega^{\star})$$
$$= \operatorname{Tr}(e\omega^{\star}), \tag{C8}$$

where the first two lines are the same as Eq. (C5), and let  $\alpha := \operatorname{Tr}[(\operatorname{id}_A \otimes \tilde{\Gamma}_1)(\omega)]$ . In the third line, we chose  $\omega' \in \mathbb{F}$  such that  $(\operatorname{id}_A \otimes \tilde{\Gamma}_1)(\omega) = \alpha \omega'$  holds, and similarly,  $\omega'' \in \mathbb{F}$  such that  $(\operatorname{id}_A \otimes \tilde{\Gamma}_0)(\omega) = (1 - \alpha)\omega''$  holds. Since  $\mathbb{F}$  preserves probabilistic transformations on *C*, such  $\omega'$  and  $\omega''$  exist. Note that  $\alpha + \operatorname{Tr}\left[(\operatorname{id}_A \otimes \tilde{\Gamma}_0)(\omega)\right] = 1$  holds since  $\tilde{\Gamma}_1 + \tilde{\Gamma}_0$  is a channel. The fourth line follows from  $\operatorname{Tr}(e\omega') \leq \operatorname{Tr}(e\omega^*)$  and Eq. (C7). Therefore, from Eqs. (C4) and (C8), Eq. (C6) with  $\varepsilon' = \varepsilon = 0$  holds.

**Lemma 7** Arbitrarily choose two systems *A* and *C*, a natural number *N*, and a collection of subchannels  $\{\tilde{\Lambda}_n\}_{n=1}^N$  from *A* to *C*. Define the collection of channels  $\{\Lambda_{i,q,r} \in Chn_{A \to B \otimes C}\}_{(i,q,r)=(1,1,1)}^{(N,N_C,N_C)}$  by

$$\Lambda_{i,q,r}(\sigma) = (\tilde{X}^{i-1} \otimes X^{q-1} Z^{r-1}) \left[ \sum_{n=1}^{N} |n\rangle \langle n| \otimes \tilde{\Lambda}_{n}(\sigma) \right] (\tilde{X}^{1-i} \otimes Z^{1-r} X^{1-q}), \qquad \forall \sigma \in \mathsf{Den}_{A}, \tag{C9}$$

where *B* is an *N*-level system,  $\{|n\rangle\}_{n=1}^{N}$  is the computational basis of *B*,  $\tilde{X}$  is the generalized Pauli-*X* matrix of order *N*, and *X* (resp. *Z*) is the generalized Pauli-*X* (resp. Pauli-*Z*) matrix of order *N*<sub>C</sub>. Also, let us consider the equal prior probabilities  $\{p_{i,q,r} \coloneqq 1/(NN_{C}^{2})\}_{(i,q,r)=(1,1,1)}^{(N,N_{C},N_{C})}$ . Then, the following two properties hold.

(1) For any measurement  $\Pi := \{\Pi_{i,q,r}\}_{(i,q,r)=(1,1,1)}^{(N,N_C,N_C)}$  on  $B \otimes C \otimes C$ , there exists a measurement  $\Pi^{\text{sym}} := \{\Pi_{i,q,r}^{\text{sym}}\}_{(i,q,r)=(1,1,1)}^{(N,N_C,N_C)}$  on  $B \otimes C \otimes C$  satisfying

$$P_{\mathsf{S}}(\rho,\Pi;\{p_{i,q,r},\Lambda_{i,q,r}\}) = P_{\mathsf{S}}(\rho,\Pi^{\mathrm{sym}};\{p_{i,q,r},\Lambda_{i,q,r}\}) = \mathrm{Tr}\left[\Pi^{\mathrm{sym}}_{1,1,1}\cdot(\Lambda_{1,1,1}\otimes\mathsf{id}_{\mathcal{C}})(\rho)\right], \qquad \forall \rho \in \mathsf{Den}_{A\otimes \mathcal{C}}$$
(C10)

and

$$\Pi_{i,q,r}^{\text{sym}} = (\tilde{X}^{i-1} \otimes X^{q-1} Z^{r-1} \otimes \text{id}_C) \Pi_{1,1,1}^{\text{sym}} (\tilde{X}^{1-i} \otimes Z^{1-r} X^{1-q} \otimes \text{id}_C).$$
(C11)

(2) For such  $\Pi^{sym}$ , let

$$\tilde{\Gamma}_{n} \coloneqq N_{C} \left[ \mathsf{id}_{C} \otimes \operatorname{Tr} \left[ \Pi_{1,1,1}^{\operatorname{sym}} \cdot (|n\rangle \langle n| \otimes \mathsf{id}_{C \otimes C}) \right] \right] \circ (\Phi_{C} \otimes \mathsf{id}_{C}) \in \mathsf{CP}_{C \to C}, \qquad n \in \{1, 2, \dots, N\};$$
(C12)

then,  $\{\tilde{\Gamma}_n\}_{n=1}^N$  are subchannels on *C* that satisfy

$$\sum_{n=1}^{N} \operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{n} \otimes \tilde{\Gamma}_{n})(\rho)\right] = N_{C} P_{S}(\rho, \Pi^{\operatorname{sym}}; \{p_{i,q,r}, \Lambda_{i,q,r}\}), \qquad \forall \rho \in \operatorname{\mathsf{Den}}_{A \otimes C}.$$
(C13)

**Proof** (1): Let us consider the following group:

$$\mathcal{G} \coloneqq \left\{ g_{i,q,r} \coloneqq (\tilde{X}^i \otimes X^q Z^r \otimes \mathsf{id}_C) \cdot - \cdot (\tilde{X}^{-i} \otimes Z^{-r} X^{-q} \otimes \mathsf{id}_C) \right\}_{(i,q,r)=(1,1,1)}^{(N,N_C,N_C)} \subset \mathsf{Chn}_{B \otimes C \otimes C \to B \otimes C \otimes C}.$$
(C14)

Since  $\Lambda_{[i+i']_N, [q+q']_{N_C}, [r+r']_{N_C}} \otimes id_C = g_{i,q,r} \circ (\Lambda_{i',q',r'} \otimes id_C)$  holds for any i, i', q, q', r, r' (where  $[n]_N$  is defined in Eq. (B1)), the collection  $\{\Lambda_{i,q,r} \otimes id_C\}_{(i,q,r)=(1,1,1)}^{(N,N_C,N_C)}$  is *G*-covariant. Note that the corresponding group *G* is

$$G \coloneqq \{(i, q, r) \mid i \in \{1, 2, \dots, N\}, q, r \in \{1, 2, \dots, N_C\}\}$$

with the product  $(i, q, r) \cdot (i', q', r')$  being  $(\llbracket i + i' \rrbracket_N, \llbracket q + q' \rrbracket_{N_C}, \llbracket r + r' \rrbracket_{N_C})$  and the identity element  $(N, N_C, N_C)$ . Therefore, from Lemma 5, there exists a *G*-covariant measurement  $\Pi^{\text{sym}}$  (i.e., satisfying Eq. (C11)) that satisfies Eq. (C10).

(2): We have

$$\operatorname{Tr} \circ \left(\sum_{n=1}^{N} \widetilde{\Gamma}_{n}\right) = N_{C} \operatorname{Tr} \circ \sum_{n=1}^{N} \left[ \operatorname{id}_{C} \otimes \operatorname{Tr} \left[ \Pi_{1,1,1}^{\operatorname{sym}} \cdot \left( |n\rangle \langle n| \otimes \operatorname{id}_{C \otimes C} \right) \right] \right] \circ \left( \Phi_{C} \otimes \operatorname{id}_{C} \right)$$
$$= N_{C} \operatorname{Tr} \circ \left[ \operatorname{id}_{C} \otimes \operatorname{Tr} \left[ \Pi_{1,1,1}^{\operatorname{sym}} \cdot \left( I_{N} \otimes \operatorname{id}_{C \otimes C} \right) \right] \right] \circ \left( \Phi_{C} \otimes \operatorname{id}_{C} \right)$$
$$= N_{C} \operatorname{Tr} \left[ \Pi_{1,1,1}^{\operatorname{sym}} \cdot \left( I_{N} \otimes I_{N_{C}} \otimes \operatorname{id}_{C} \right) \right]$$
$$= N_{C} \operatorname{Tr} \left[ \left( \operatorname{Tr}_{B \otimes C} \Pi_{1,1,1}^{\operatorname{sym}} \right) \cdot - \right], \tag{C15}$$

where  $\operatorname{Tr}_{B\otimes C}$  is the partial trace over the first two systems *B* and *C* of the composite system  $B \otimes C \otimes C$ . Since  $\Pi^{\text{sym}}$  is a measurement, we have

$$I_N \otimes I_{N_C} \otimes I_{N_C} = \sum_{i=1}^N \sum_{q=1}^{N_C} \sum_{r=1}^{N_C} \prod_{i,q,r}^{\text{sym}} = \sum_{i=1}^N \sum_{q=1}^{N_C} \sum_{r=1}^{N_C} g_{i-1,q-1,r-1}(\Pi_{1,1,1}^{\text{sym}}) = I_N \otimes I_{N_C} \otimes N_C \operatorname{Tr}_{B \otimes C} \Pi_{1,1,1}^{\text{sym}}$$

where the last equality follows from  $\sum_{i=1}^{N} \sum_{q=1}^{N_C} \sum_{r=1}^{N_C} g_{i-1,q-1,r-1} = I_N \otimes I_{N_C} \otimes (N_C \operatorname{Tr}_{B \otimes C} -)$ . This gives  $N_C \operatorname{Tr}_{B \otimes C} \Pi_{1,1,1}^{\text{sym}} = I_{N_C}$ , and thus  $\operatorname{Tr} \circ \left(\sum_{n=1}^{N} \tilde{\Gamma}_n\right) = \operatorname{Tr} -$  holds from Eq. (C15). Therefore,  $\sum_{n=1}^{N} \tilde{\Gamma}_n$  is a channel, i.e.,  $\{\tilde{\Gamma}_n\}_{n=1}^{N}$  are subchannels. We obtain

$$\begin{split} \sum_{n=1}^{N} \operatorname{Tr} \left[ \Phi_{C} \cdot (\tilde{\Lambda}_{n} \otimes \tilde{\Gamma}_{n})(\rho) \right] &= N_{C} \sum_{n=1}^{N} \operatorname{Tr} \left[ \Phi_{C} \cdot \left[ \tilde{\Lambda}_{n} \otimes \left[ \operatorname{id}_{C} \otimes \operatorname{Tr} \left[ \Pi_{1,1,1}^{\operatorname{sym}} \cdot (|n\rangle \langle n| \otimes \operatorname{id}_{C \otimes C}) \right] \right] \circ (\Phi_{C} \otimes \operatorname{id}_{C}) \right] (\rho) \right] \\ &= N_{C} \sum_{n=1}^{N} \operatorname{Tr} \left[ \Phi_{C} \cdot \left[ \left[ \operatorname{id}_{C} \otimes \operatorname{Tr} \left[ \Pi_{1,1,1}^{\operatorname{sym}} \cdot (|n\rangle \langle n| \otimes \operatorname{id}_{C \otimes C}) \right] \right] \circ (\tilde{\Lambda}_{n} \otimes \Phi_{C} \otimes \operatorname{id}_{C}) \right] (\rho) \right] \\ &= N_{C} \sum_{n=1}^{N} \operatorname{Tr} \left[ \Pi_{1,1,1}^{\operatorname{sym}} \cdot \left[ (|n\rangle \langle n| \otimes \operatorname{id}_{C \otimes C}) \circ (\tilde{\Lambda}_{n} \otimes \operatorname{id}_{C}) \right] (\rho) \right] \\ &= N_{C} \sum_{n=1}^{N} \operatorname{Tr} \left[ \Pi_{1,1,1}^{\operatorname{sym}} \cdot (|n\rangle \langle n| \otimes \tilde{\Lambda}_{n} \otimes \operatorname{id}_{C}) (\rho) \right] \\ &= N_{C} \sum_{n=1}^{N} \operatorname{Tr} \left[ \Pi_{1,1,1}^{\operatorname{sym}} \cdot (\Lambda_{1,1,1} \otimes \operatorname{id}_{C}) (\rho) \right] \\ &= N_{C} P_{S}(\rho, \Pi^{\operatorname{sym}}; \{p_{i,q,r}, \Lambda_{i,q,r}\}), \end{split}$$

and thus Eq. (C13) holds. The last line follows from the right-hand equality of Eq. (C10).

**Proof of Theorem 3** Since  $G_C(\rho, \mathbb{F}) \leq 1 + R_{\mathbb{F}}(\rho)$  holds as stated in the main text, it suffices to show  $G_C(\rho, \mathbb{F}) \geq 1 + R_{\mathbb{F}}(\rho)$ . Choose an arbitrary positive real number  $\varepsilon$ , and consider a collection of subchannels  $\{\tilde{\Lambda}_n\}_{n=1}^N$  from *A* to *C* obtained by Lemma 6. Define the collection of channels  $\{\Lambda_{i,q,r} \in Chn_{A \to B \otimes C}\}_{(i,q,r)=(1,1,1)}^{(N,N_C,N_C)}$  by Eq. (C9), and consider the equal prior probabilities  $\{p_{i,q,r} \coloneqq 1/(NN_C^2)\}_{(i,q,r)=(1,1,1)}^{(N,N_C,N_C)}$ . Furthermore, define the measurement  $\Psi \coloneqq \{\Psi_{i,q,r}\}_{(i,q,r)=(1,1,1)}^{(N,N_C,N_C)}$  on  $B \otimes C \otimes C$  by

$$\Psi_{i,q,r} \coloneqq (\tilde{X}^{i-1} \otimes X^{q-1} Z^{r-1} \otimes \mathsf{id}_C)(|1\rangle \langle 1| \otimes N_C^{-1} \Phi_C)(\tilde{X}^{1-i} \otimes Z^{1-r} X^{1-q} \otimes \mathsf{id}_C).$$
(C16)

Define  $\mathcal{G}$  by Eq. (C14); then, both  $\{p_{i,q,r}, \Lambda_{i,q,r} \otimes id_C\}$  and  $\Psi$  are  $\mathcal{G}$ -covariant. Let us consider  $\tilde{\Gamma}_n$  obtained by substituting  $\Psi_{1,1,1} = |1\rangle \langle 1| \otimes N_C^{-1} \Phi_C$  into  $\Pi_{1,1,1}^{\text{sym}}$  in Eq. (C12). Then, from

$$\tilde{\Gamma}_n = [\mathsf{id}_C \otimes \mathrm{Tr}[(|1\rangle \langle 1| \otimes \Phi_C) \cdot (|n\rangle \langle n| \otimes \mathsf{id}_{C \otimes C})]] \circ (\Phi_C \otimes \mathsf{id}_C) = |\langle 1|n\rangle|^2 \cdot \mathsf{id}_C,$$

 $\tilde{\Gamma}_1 = \mathrm{id}_C$  and  $\tilde{\Gamma}_2 = \tilde{\Gamma}_3 = \cdots = \tilde{\Gamma}_N = 0$  hold, and thus we obtain  $\mathrm{Tr}\left[\Phi_C \cdot (\tilde{\Lambda}_1 \otimes \mathrm{id}_C)(\rho)\right] = N_C P_S(\rho, \Psi; \{p_{i,q,r}, \Lambda_{i,q,r}\})$  from Eq. (C13) with  $\Pi^{\mathrm{sym}}$  substituted by  $\Psi$ . Therefore, we have

$$P_{\mathcal{S}}(\rho; \{p_{i,q,r}, \Lambda_{i,q,r}\}) \ge P_{\mathcal{S}}(\rho, \Psi; \{p_{i,q,r}, \Lambda_{i,q,r}\}) = N_{C}^{-1} \operatorname{Tr} \left[ \Phi_{C} \cdot (\tilde{\Lambda}_{1} \otimes \mathsf{id}_{C})(\rho) \right].$$
(C17)

Let  $\omega^*$  be  $\omega \in \text{cl} \mathbb{F}$  that maximizes  $P_S(\omega; \{p_{i,q,r}, \Lambda_{i,q,r}\})$ . From Lemma 7, there exists a  $\mathcal{G}$ -covariant measurement  $\Pi^{\text{sym}}$  that satisfies  $P_S(\omega^*; \{p_{i,q,r}, \Lambda_{i,q,r}\}) = P_S(\omega^*, \Pi^{\text{sym}}; \{p_{i,q,r}, \Lambda_{i,q,r}\})$ . Define the collection of subchannels  $\{\tilde{\Gamma}_n\}_{n=1}^N$  by Eq. (C12); then, we have

$$\sup_{\omega \in \mathbb{F}} P_{S}(\omega; \{p_{i,q,r}, \Lambda_{i,q,r}\}) = P_{S}(\omega^{\star}, \Pi^{\text{sym}}; \{p_{i,q,r}, \Lambda_{i,q,r}\}) = N_{C}^{-1} \sum_{n=1}^{N} \text{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{n} \otimes \tilde{\Gamma}_{n})(\omega^{\star})\right],$$
(C18)

where the right-hand equality follows from Eq. (C13). Thus, from Eqs. (C17) and (C18), we obtain

$$\frac{P_{S}(\rho; \{p_{i,q,r}, \Lambda_{i,q,r}\})}{\sup_{\omega \in \mathbb{F}} P_{S}(\omega; \{p_{i,q,r}, \Lambda_{i,q,r}\})} \geq \frac{\operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{1} \otimes \mathsf{id}_{C})(\rho)\right]}{\sum_{n=1}^{N} \operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{n} \otimes \tilde{\Gamma}_{n})(\omega^{\star})\right]} \geq \frac{\operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{n} \otimes \tilde{\Gamma}_{n})(\omega)\right]}{\sup_{\omega \in \mathbb{F}} \sum_{n=1}^{N} \operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{n} \otimes \tilde{\Gamma}_{n})(\omega)\right]} \geq \frac{1 + R_{\mathbb{F}}(\rho)}{1 + \varepsilon}, \quad (C19)$$

where the second inequality follows from

$$\sum_{n=1}^{N} \operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{n} \otimes \tilde{\Gamma}_{n})(\omega^{\star})\right] \leq \max_{\omega \in cl \mathbb{F}} \sum_{n=1}^{N} \operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{n} \otimes \tilde{\Gamma}_{n})(\omega)\right] = \sup_{\omega \in \mathbb{F}} \sum_{n=1}^{N} \operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{n} \otimes \tilde{\Gamma}_{n})(\omega)\right]$$

and the last inequality follows from Lemma 6. Since this equation holds for any positive real number  $\varepsilon$ , we have  $G_C(\rho, \mathbb{F}) \ge 1 + R_{\mathbb{F}}(\rho)$ . Therefore,  $G_C(\rho, \mathbb{F}) = 1 + R_{\mathbb{F}}(\rho)$  holds.

In particular, if  $\mathbb{F}$  preserves probabilistic transformations on *C*, then Eq. (C19) with  $\varepsilon = 0$  holds, and thus the supremum  $\sup_{\{p_{i,q,r},\Lambda_{i,q,r}\}}$  of  $G_C(\rho, \mathbb{F})$  can be replaced by the maximum  $\max_{\{p_{i,q,r},\Lambda_{i,q,r}\}}$ . We provide two typical examples of subsets of  $\text{Den}_{A\otimes C}$  that preserve probabilistic transformations on *C*. The first example is the set of states with Schmidt number at most *k* (where *k* is any natural number) [47]. The second example is the set of all unsteerable states from *A* to *C* [53]. Note that the set of all unsteerable states from *C* to *A* does not necessarily preserve probabilistic transformations on *C* [54].

### Appendix D: The case in which positive definite free states do not exist

## 1. Without considering auxiliary systems

Let us consider the set of free states  $\mathbb{F}$  of an arbitrary system A. Assume that  $\mathbb{F}$  is not empty so that  $G(\rho, \mathbb{F})$  and  $R_{\mathbb{F}}(\rho)$  are well-defined for at least one state  $\rho \in \text{Den}_A$ . For any subset T of Den<sub>A</sub>, let  $S_T$  be the set of all  $\rho \in \text{Den}_A$  such that there exists  $\omega \in T$  and a positive real number c satisfying  $c\rho \leq \omega$ .  $S_T = \text{Den}_A$  is equivalent to T containing a positive definite matrix.

The following lemma holds.

**Lemma 8** For any  $\rho \in \text{Den}_A$ , (1)  $\rho \in S_{\text{co}\mathbb{F}}$ , (2)  $R_{\text{co}\mathbb{F}}(\rho) < \infty$ , and (3)  $G(\rho,\mathbb{F}) < \infty$  are all equivalent.

**Proof** (1)  $\Rightarrow$  (2): Assume  $\rho \in S_{coF}$ ; then, there exists  $\omega \in coF$  and a positive real number *c* such that  $c\rho \leq \omega$  holds.  $c \leq 1$  clearly holds, and if c = 1 holds, then  $\rho = \omega$  implies  $R_{coF}(\rho) = 0$ . If c < 1 holds, then  $\lambda := \frac{1}{c} - 1$  and  $\tau := \frac{\omega - c\rho}{1 - c}$  satisfy  $\tau \in Den_A$  and

$$\frac{\rho+\lambda\tau}{1+\lambda}=c\rho+(1-c)\tau=c\rho+(\omega-c\rho)=\omega.$$

Thus, we have  $R_{\operatorname{co}\mathbb{F}}(\rho) \leq \lambda < \infty$ .

(2)  $\Rightarrow$  (3):  $G(\rho, \mathbb{F}) = G(\rho, \operatorname{co} \mathbb{F}) \leq 1 + R_{\operatorname{co}\mathbb{F}}(\rho) < \infty$  obviously holds, where the equality follows from the fact the proof of  $G(\rho, \mathbb{F}) = G(\rho, \operatorname{co} \mathbb{F})$  in Corollary 2 applies directly, and the first inequality follows from the fact the proof of  $G(\rho, \mathbb{F}) \leq 1 + R_{\mathbb{F}}(\rho)$  in Theorem 1 with  $\mathbb{F}$  replaced by  $\operatorname{co} \mathbb{F}$  applies directly.

(3)  $\Rightarrow$  (1): We show the contrapositive, i.e.,  $G(\rho, \mathbb{F}) = \infty$  for any  $\rho \notin S_{co\mathbb{F}}$ . Let **V** be the smallest complex vector space containing the support spaces of all  $\omega \in co\mathbb{F}$ ; then,  $S_{co\mathbb{F}} = \{\sigma \in \text{Den}_A \mid \text{supp } \sigma \subseteq \mathbf{V}\}$  holds. Let  $P \in \text{Pos}_A$  be the projection matrix onto the orthogonal complement of **V**.  $\text{Tr}(P\omega) = 0$  holds for any  $\omega \in \mathbb{F}$  since  $\text{supp } \omega \subseteq \mathbf{V}$  holds. Also,  $\text{Tr}(P\rho) > 0$  holds from  $\text{supp } \rho \notin \mathbf{V}$ . Choose any natural number *N* and an *N*-level system *B*. Let  $p_n \coloneqq 1/N$  ( $\forall n \in \{1, 2, ..., N\}$ ) and define channels  $\Lambda_1, \ldots, \Lambda_N$  from *A* to *B* by

$$\Lambda_n(\sigma) = \operatorname{Tr}(P\sigma) |n\rangle \langle n| + \frac{1 - \operatorname{Tr}(P\sigma)}{N - 1} (I_N - |n\rangle \langle n|), \qquad \forall \sigma \in \mathsf{Den}_A.$$

Then, we can use a similar method as in the proof of Theorem 1. Specifically, let  $\mathcal{G} := \{X^k(-)X^{-k}\}_{k=1}^N$ , where X is the generalized Pauli-X matrix of order N; then,  $\{\Lambda_n\}$  is  $\mathcal{G}$ -covariant. Thus, from Lemma 5, for each measurement  $\Pi$ , there exists a  $\mathcal{G}$ -covariant measurement  $\Pi^{\text{sym}}$  satisfying

$$P_{S}(\sigma,\Pi;\{p_{n},\Lambda_{n}\}) = \operatorname{Tr}\left[\Pi_{1}^{\operatorname{sym}}\cdot\Lambda_{1}(\sigma)\right] = c\operatorname{Tr}(P\sigma) + (1-c)\frac{1-\operatorname{Tr}(P\sigma)}{N-1}, \qquad \forall \sigma \in \operatorname{Den}_{A}, \tag{D1}$$

where  $c := \langle 1 | \Pi_1^{\text{sym}} | 1 \rangle$ . The right-hand equality follows from  $\text{Tr} \Pi_1^{\text{sym}} = 1$ , which is derived from  $\sum_{n=1}^N \Pi_n^{\text{sym}} = I_N$ . Therefore, we have that, for each  $\omega \in \mathbb{F}$ ,

$$P_{\mathsf{S}}(\omega,\Pi;\{p_n,\Lambda_n\}) = c\operatorname{Tr}(P\omega) + (1-c)\frac{1-\operatorname{Tr}(P\omega)}{N-1} = \frac{1-c}{N-1} \le \frac{1}{N-1}$$

For a measurement  $\Pi$  satisfying  $c = \langle 1 | \Pi_1^{\text{sym}} | 1 \rangle = 1$ , since  $P_{S}(\rho, \Pi; \{p_n, \Lambda_n\}) = \text{Tr}(P\rho)$  holds from Eq. (D1), we obtain

$$G(\rho, \mathbb{F}) \ge \frac{P_{\mathsf{S}}(\rho; \{p_n, \Lambda_n\})}{\sup_{\omega \in \mathbb{F}} P_{\mathsf{S}}(\omega; \{p_n, \Lambda_n\})} \ge \frac{\operatorname{Tr}(P\rho)}{\frac{1}{N-1}} = (N-1)\operatorname{Tr}(P\rho).$$

Thus, taking the limit as  $N \to \infty$  yields  $G(\rho, \mathbb{F}) = \infty$ .

It is easy to see that Theorem 1 and Corollary 2 hold when  $R_{co\mathbb{F}}(\rho) < \infty$ , or equivalently  $G(\rho, \mathbb{F}) < \infty$ , holds. That is, even if co  $\mathbb{F}$  does not contain a positive definite matrix, Theorem 1 and Corollary 2 hold for any  $\rho \in S_{co\mathbb{F}}$ , and, from Lemma 8,  $R_{co\mathbb{F}}(\rho) = \infty$  and  $G(\rho, \mathbb{F}) = \infty$  hold for any  $\rho \notin S_{co\mathbb{F}}$ .

# 2. Considering auxiliary systems

For any two systems *A* and *C*, let us consider the set of free states  $\mathbb{F}$  of the composite system  $A \otimes C$ . Assume that  $\mathbb{F}$  is not empty; then, the following corollary holds.

**Corollary 9** For any  $\rho \in \text{Den}_{A\otimes C}$ , (1)  $\rho \in S_{co \mathbb{F}_C}$ , (2)  $R_{co \mathbb{F}_C}(\rho) < \infty$ , and (3)  $G_C(\rho, \mathbb{F}_C) < \infty$  are all equivalent.

**Proof** Substituting  $\mathbb{F}_C$  for  $\mathbb{F}$  in Lemma 8 gives (1)  $\Leftrightarrow$  (2). If  $R_{co\mathbb{F}_C}(\rho) < \infty$  holds, then we have  $G_C(\rho, \mathbb{F}_C) \le G(\rho, \mathbb{F}_C) < \infty$ , where the right-hand inequality follows from (2)  $\Rightarrow$  (3) from Lemma 8 with  $\mathbb{F}$  replaced by  $\mathbb{F}_C$ . Thus, (2)  $\Rightarrow$  (3) holds. It remains to show (3)  $\Rightarrow$  (1).

We show the contrapositive of  $(3) \Rightarrow (1)$ , i.e.,  $G_C(\rho, \mathbb{F}_C) = \infty$ , or equivalently  $G_C(\rho, \operatorname{co} \mathbb{F}_C) = \infty$ , for any  $\rho \notin S_{\operatorname{co} \mathbb{F}_C}$ . From the contrapositive of  $(1) \leftarrow (2)$ , we have  $R_{\operatorname{co} \mathbb{F}_C}(\rho) = \infty$ . Choose an arbitrary positive real number R, and a feasible solution x of the problem with  $\operatorname{co} \mathbb{F}_C$  substituted for  $\mathbb{F}$  in Problem (5) that satisfies  $\operatorname{Tr}(x\rho) - 1 \ge R$ , i.e.,  $x \in \operatorname{Pos}_{A \otimes C}$  satisfying

$$\operatorname{Tr}(x\rho) \ge 1 + R$$
,  $\operatorname{Tr}(x\omega) \le 1 \ (\forall \omega \in \operatorname{co} \mathbb{F}_C).$ 

Since the optimal value of this problem is  $R_{\operatorname{co}\mathbb{F}_C}(\rho) = \infty$ , such *x* exists. Fix a positive real number  $\varepsilon$ ; then, similarly to Lemma 6, there exist a natural number *N* and a collection of subchannels  $\{\tilde{\Lambda}_n\}_{n=1}^N$  from *A* to *C* such that

$$\frac{\operatorname{Tr}\left[\Phi_{C}\cdot(\tilde{\Lambda}_{1}\otimes \mathsf{id}_{C})(\rho)\right]}{\sup_{\omega\in\mathrm{co}\,\mathbb{F}_{C}}\sum_{n=1}^{N}\operatorname{Tr}\left[\Phi_{C}\cdot(\tilde{\Lambda}_{n}\otimes\tilde{\Gamma}_{n})(\omega)\right]} \geq \frac{1+R}{1+\varepsilon}$$
(D2)

holds for any subchannels  $\{\tilde{\Gamma}_n\}_{n=1}^N$  on *C*. Indeed, we can use *x* instead of  $x^*$  in the proof of Lemma 6 (note that co  $\mathbb{F}_C$  preserves operations on *C*). The rest can be proved similarly to the proof of Theorem 3. Define the collection of channels  $\{\Lambda_{i,q,r} \in Chn_{A \to B \otimes C}\}_{(i,q,r)=(1,1,1)}^{(N,N_C,N_C)}$  by Eq. (C9), and consider the equal prior probabilities  $\{p_{i,q,r} \coloneqq 1/(NN_C^2)\}_{(i,q,r)=(1,1,1)}^{(N,N_C,N_C)}$ . Also, let us consider the measurement  $\Psi \coloneqq \{\Psi_{i,q,r}\}_{(i,q,r)=(1,1,1)}^{(N,N_C,N_C)}$  on  $B \otimes C \otimes C$  given by Eq. (C16). Then, similarly to Eq. (C17), we have

$$P_{S}(\rho; \{p_{i,q,r}, \Lambda_{i,q,r}\}) \ge N_{C}^{-1} \operatorname{Tr} \left[ \Phi_{C} \cdot (\tilde{\Lambda}_{1} \otimes \mathsf{id}_{C})(\rho) \right].$$
(D3)

Let  $\omega^*$  be  $\omega \in cl(co \mathbb{F}_C)$  that maximizes  $P_S(\omega; \{p_{i,q,r}, \Lambda_{i,q,r}\})$ . For the group  $\mathcal{G}$  given by Eq. (C14), from Lemma 7, there exists a  $\mathcal{G}$ -covariant measurement  $\Pi^{sym}$  that satisfies  $P_S(\omega^*; \{p_{i,q,r}, \Lambda_{i,q,r}\}) = P_S(\omega^*, \Pi^{sym}; \{p_{i,q,r}, \Lambda_{i,q,r}\})$ . Define the collection of subchannels  $\{\tilde{\Gamma}_n\}_{n=1}^N$  by Eq. (C12); then, similarly to Eq. (C18), we have

$$\sup_{\omega \in \operatorname{co} \mathbb{F}_{C}} P_{S}(\omega; \{p_{i,q,r}, \Lambda_{i,q,r}\}) = N_{C}^{-1} \sum_{n=1}^{N} \operatorname{Tr} \left[ \Phi_{C} \cdot (\tilde{\Lambda}_{n} \otimes \tilde{\Gamma}_{n})(\omega^{\star}) \right].$$
(D4)

Therefore, from Eqs. (D3) and (D4), we obtain

$$\frac{P_{\mathsf{S}}(\rho; \{p_{i,q,r}, \Lambda_{i,q,r}\})}{\sup_{\omega \in \operatorname{co} \mathbb{F}_{C}} P_{\mathsf{S}}(\omega; \{p_{i,q,r}, \Lambda_{i,q,r}\})} \geq \frac{\operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{1} \otimes \operatorname{id}_{C})(\rho)\right]}{\sum_{n=1}^{N} \operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{n} \otimes \tilde{\Gamma}_{n})(\omega^{\star})\right]} \geq \frac{\operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{1} \otimes \operatorname{id}_{C})(\rho)\right]}{\sup_{\omega \in \operatorname{co} \mathbb{F}_{C}} \sum_{n=1}^{N} \operatorname{Tr}\left[\Phi_{C} \cdot (\tilde{\Lambda}_{n} \otimes \tilde{\Gamma}_{n})(\omega)\right]} \geq \frac{1+R}{1+\varepsilon},$$

where the last inequality follows from Eq. (D2). Taking the limit as  $R \to \infty$ , we obtain  $G_C(\rho, \operatorname{co} \mathbb{F}_C) = \infty$ .

Similarly to Theorem 1 and Corollary 2, it is easy to see that Theorem 3 and Corollary 4 hold when  $R_{co\mathbb{F}_C}(\rho) < \infty$ , or equivalently  $G_C(\rho, \mathbb{F}_C) < \infty$ , holds. That is, even if  $co\mathbb{F}_C$  does not contain a positive definite matrix, Theorem 3 and Corollary 4 hold for any  $\rho \in S_{co\mathbb{F}_C}$ , and, from Corollary 9,  $R_{co\mathbb{F}_C}(\rho) = \infty$  and  $G_C(\rho, \mathbb{F}_C) = \infty$  hold for any  $\rho \notin S_{co\mathbb{F}_C}$ .
