Abstract

Concept erasure techniques have recently gained significant attention for their potential to remove unwanted concepts from text-to-image models. While these methods often demonstrate success in controlled scenarios, their robustness in real-world applications and readiness for deployment remain uncertain. In this work, we identify a critical gap in evaluating sanitized models, particularly in terms of their performance across various concept dimensions. We systematically investigate the failure modes of current concept erasure techniques, with a focus on visually similar, binomial, and semantically related concepts. We propose that these interconnected relationships give rise to a phenomenon of concept entanglement resulting in ripple effects and degradation in image quality. To facilitate more comprehensive evaluation, we introduce EraseBENCH, a multidimensional benchmark designed to assess concept erasure methods with greater depth. Our dataset includes over 100 diverse concepts and more than 1,000 tailored prompts, paired with a comprehensive suite of metrics that together offer a holistic view of erasure efficacy. Our findings reveal that even state-of-the-art techniques struggle with maintaining quality post-erasure, indicating that these approaches are not yet ready for real-world deployment. This highlights the gap in reliability of the concept erasure techniques.

1. Introduction

As text-to-image generative models [6, 15, 16, 31, 33, 37] have become increasingly popular and widely adopted, the demand for techniques that allow for the targeted removal of specific concepts has grown in parallel. Concept erasure methods [7, 8, 13, 23, 25, 27, 47] promise to address important concerns such as ensuring the safe deployment of models by removing undesirable or harmful concepts [7, 10, 44].

Figure 1. The ripple effects of concept erasure on 'entangled' concepts. The images on the left show the output generated by Stable Diffusion (SD) prior to erasure, while those on the right depict the post-erasure results. We observe a noticeable negative impact on the generation quality of concept that are not erased. Assessment using our EraseBench framework helps identify these effects and provides a framework to evaluate the reliability and robustness of concept erasure techniques.

Whether applied to mitigate bias [3, 27, 38], protect privacy [7, 10, 17, 44], or filter out unwanted content. These techniques aim to create "sanitized" models capable of generating content without triggering unwanted associations.

Generative models interact with a variety of contexts and need to handle diverse, interrelated concepts. The ability to erase one concept without inadvertently affecting related or visually similar concepts remains a critical challenge. For example, erasing "cat" from a model should ideally remove

[†] The work was done during an internship at Google.

all representations of a cat, yet leave semantically or visually related concepts like "lion" unaffected. Figure 1 shows various failures modes observed in state-of-the-art concept erasure techniques. These techniques are highly sensitive after a concept has been erased. Closely related non-target concepts often suffer unintended consequences, resulting in poor-quality image generation or even complete mode collapse. In this work, we argue that current concept erasure techniques often fall short in such real-world conditions. Specifically, we show that even state-of-the-art methods are vulnerable to failure modes when tasked with erasing concepts that are visually similar, binomially related, or semantically entangled. This lack of robustness indicates that these models may not be ready for deployment in sensitive applications and may have ripple effects that extend beyond their intended targets, potentially leading to unintended consequences such as the distortion of related concepts, which compromises the overall reliability of the textto-image models.

To address this gap, we introduce EraseBENCH, a comprehensive benchmark designed to stress-test concept erasure techniques across multiple dimensions. By evaluating models on a wide range of concepts—spanning different domains, relationships, and complexities—EraseBENCH enables more realistic assessments of concept erasure performance. We present a novel dataset of over 100 diverse concepts and more than 1,000 tailored prompts, along with a suite of metrics to evaluate erasure efficacy, quality retention, and potential leakage of erased concepts. Through our evaluations, we reveal that many erasure techniques struggle with maintaining the generation quality and integrity post-erasure, underscoring the need for continued research in this space.

Our main contributions are summarized as follows:

- We identify key evaluation dimensions where most concept erasure techniques exhibit vulnerabilities, particularly when handling visually similar, binomial, and semantically related concepts.
- 2. We present EraseBench, a comprehensive, multidimensional benchmark designed to rigorously evaluate the robustness and efficacy of concept erasure techniques across a diverse set of concepts and prompts.
- 3. We used a suite of evaluation metrics that captures the effectiveness of concept erasure methods, offering a more holistic assessment of their performance.
- 4. We benchmark five state-of-the-art concept erasure techniques on EraseBench and through this evaluation, demonstrate that many of the current concept erasure techniques are not yet ready for real-world deployment, highlighting significant gaps in their reliability and robustness.

2. Related Works

Text-to-image models have witnessed remarkable advancements since the foundational works [24, 50], driven by breakthroughs in model architectures [5, 14, 36, 41, 45, 49], state-of-the-art generative modeling techniques [1, 2, 9, 11, 18, 19, 22, 22, 26, 30–33, 42], and the availability of large high-quality datasets [20, 34]. These improvements have significantly enhanced their capability to generate realistic and diverse images from textual descriptions, pushing the boundaries of creativity and application. In light of recent advancements in text-to-image models, greater attention has been directed towards reliability considerations. There is a wide variety of concept erasure techniques, each utilizing distinct methods and technologies to achieve concept removal. These approaches range from closed form solutions [8], applying targeted fine-tuning [7, 13, 23, 47], and even using efficient architectures such as adapters [13, 23]. We provide in the Appendix more details about existing concept erasure techniques. Nevertheless, despite the rapid increase of these concept erasure methods, only a few works have critically examined the inherent limitations and vulnerabilities of concept erasure approaches. In particular, the work by (Pham et al.) [28] explores a fundamental vulnerability, which is the potential for erased concepts to be recovered through specific prompting. Meanwhile, other works such as of (Zhang et al.) [48] focus on the efficacy of erasure through a variety of objects and styles to evaluate if the erased concepts have been effectively removed from the model's generative capabilities. In our work, we delve into the broader impact of concept erasure, not only evaluating residual concept generation but also examining how erasure techniques may degrade the quality and fidelity of nontarget concepts. In this work we highlight the ripple effects of concept erasure on model performance and the stability of related concepts via the route of interrelated concepts.

3. Concept Entanglement

Our initial hypothesis stems from observing that many existing evaluations focused on isolated concepts, failing to account for the intricate relationships between concepts. Concept erasure techniques are designed to selectively remove specific concepts from generative models, such as text-to-image models, while maintaining the integrity of the remaining knowledge. However, this task becomes increasingly complex when dealing with concepts that are intertwined, either visually or semantically. Intertwined concepts refer to those that share *overlapping features*, either through *visual similarity*, *semantic connection*, or *frequent co-occurrence in real-world data* (i.e. binomial pairs).

The study of concept entanglement has long been a focus in the literature mainly focusing on exploring how to separate and understand intertwined concepts in representations

Figure 2. **Concept entanglement in SD**. We use DAAM [35] to obtain attribution heatmaps for Stable Diffusion (SD) generations. While "cat" and "elephant" token attributions don't overlap, for "snake" and "turtle" we can see both the snake and turtle objects being attributed, indicating an *entanglement* between concepts snake and turtle in SD. In Table. 1 we present four dimensions of *entanglement* between concepts and present empirical evidence of ripple effects post-erasure.

for better image generation [4, 40, 43, 46]. However, to our knowledge, these discussions have not yet been extended to the context of concept erasure.

Figure 2 showcases the attention attribution heatmaps [35]. For two closely related or co-occuring concepts in the prompt we observe significant overlap in the attention maps, with both concepts being activated by similar visual elements. In contrast, for two unrelated concepts—such as 'cat' and 'elephant' the attention maps remain well-separated. We argue that this *entanglement* results in unintended interference during erasure, making removing or isolating a concept significantly challenging.

In this work, we focus on evaluating the effects of entanglement within the context of concept erasure. Specifically, we analyze this entanglement under four lenses: (1) visual similarity, where concepts share visible characteristics (e.g., tigers and lions); (2) stylistic similarity in art, where visual elements convey similar aesthetics or themes; (3) binomiality, referring to culturally or popularly associated concept pairs (e.g., 'lock and key'); and (4) hierarchical relationships (i.e., subset of a superset), where one concept represents a specific instance within a broader category.

4. EraseBench

To evaluate the robustness of concept erasure techniques, we introduce a dataset designed to challenge model performance across several critical dimensions. Each dimension represents a unique relationship or similarity type that can impact the effectiveness and accuracy of concept erasure. By addressing these dimensions, the dataset provides a comprehensive foundation for understanding where current methods may falter, specifically in managing related and intertwined concepts.

4.1. Dimensions of evaluation

Visual Similarity in Objects: This category includes objects with overlapping visual features, such as cats, tigers, and lions. These classes are selected for their shared characteristics, which can lead models to generalize incorrectly, especially after a concept erasure operation. Testing against these visually similar objects helps reveal if erasure inadvertently impacts non-target but visually close concepts, indicating a lack of precision in the erasure.

Visual Similarity in Art: This dimension focuses on diverse artist signatures that share aesthetic or stylistic attributes or works by closely related artists. Since many erasure methods operate at the level of visual patterns, the subtle differences in style may not be adequately preserved, causing issues with fidelity in generation. This serves as a test for style and nuance preservation post-erasure.

Binomial Concepts: Binomial or paired concepts, like "bread and butter," present a unique challenge for erasure methods due to their strong associative links. This dimension examines how well models handle the erasure of one concept when it is closely linked with another. The goal is to identify if erasure leads to unintended consequences on the associated concept, revealing potential overreach in the erasure process.

Subset-Superset Relationships: This dimension explores hierarchical relationships or what we can call partial erasure, such as "black cat" within the broader "cat" category. Concept erasure techniques should ideally remove specific attributes or concepts while preserving general or encompassing ideas. Testing subset-superset relationships reveals whether erasure disrupts generalized concepts when only specific instances are targeted, offering insights into the granularity and control of the erasure process.

4.2. Curating EraseBench

Concept Gathering. We utilized the semantic knowledge embedded in large language models and structured sources, like the hierarchical taxonomy of ImageNet, to generate clusters of closely related concepts. By treating these language models akin to graph neural networks, we mapped visually similar concepts that share key attributes and gathered distinct sets for each dimension in EraseBench. This approach enabled the capture of nuanced similarities and relationships, essential for challenging the precision of concept erasure techniques. As for artistic style concepts, we narrowed down artists' names from the Wikiart dataset.

Concept Verification. To ensure quality and feasibility, we conducted human verification on the collected concepts. This included assessing whether existing text-to-

Figure 3. **Ripple effects of concept erasure methods across EraseBench entanglement dimensions.** All the erasure baselines display failure cases across different EraseBench tasks. Receler and MACE frequently produce images that are unrelated to the text prompt, indicating they are the most sensitive of the five concept erasure techniques. In contrast, AdvUnlearn shows slightly better robustness across certain dimensions of the benchmark. For publication purposes, if the output appears more like a painting, the human faces remain unmasked; however, for more realistic depictions, the faces have been masked. The black square was added to indicate this masking.

image models could successfully generate accurate, highquality representations of each concept. During this process, we identified and removed any concepts that models consistently struggled to render, preserving only those concepts that aligned with our benchmarks. This step ensures that the dataset maintains a high standard, with each concept suitable for rigorous testing of erasure techniques.

Prompt Construction. We employed large language models to generate a diverse set of prompts for each concept. Prompts were crafted with variations in style, complexity, and length to allow for thorough evaluation. This includes prompts that differ in level of detail (simple vs. elaborate descriptions) and length (short vs. extended prompts). With this range, we enable a finer assessment of how concept erasure techniques handle varying input types and examine the degree of degradation under different conditions.

4.2.1. Concept Description

For each evaluation dimension, we define a primary concept intended for erasure, accompanied by related non-target concepts that share visual, semantic, or contextual similarities. These non-target concepts are used to prompt the sanitized model, allowing us to observe any unintended effects. (1) Visual Similarity (Objects): We select a broad main concept, include four paraphrased (synonym) concepts, and add four visually similar concepts. For example, the main concept "cat" is erased, with synonyms like "kitten," "tabby," "siamese," and "British shorthair," while visually similar non-targets include "tiger," "cheetah," "lynx," and "panther." (2) Visual Similarity (Artist Style): Here, we erase a primary artist, e.g., Vincent van Gogh, and test model behavior on artists with similar styles, such as Paul Cézanne and Émile Bernard. (3) Subset-Superset Relationship: A primary target, such as "goldfish," is erased, while testing is done on related types like "guppy" and "koi" to assess model retention of similar concepts within the category. (4) Binomial Relations: We use pairs of closely associated concepts, such as "sun and moon," erasing one while testing generation for the other. Detailed descriptions of each concept set are available in the Appendix.

4.3. Baseline Methods

We cover a set of five methods recently proposed for concept erasure, as described next.

The Erased Stable Diffusion (ESD)[7] is a fine-tuning based approach that initially generates images that include the concept to be erased and then fine-tunes the model to "unlearn" the chosen concept. More specifically, two images are generated on a random time step: one image conditioned on the concept and one image not conditioned on the concept. Then the unconditioned image is subtracted from the conditioned image to get an image that represents the difference between the two. Finally, the model is finetuned to minimize this difference.

The Unified Concept Editing (UCE) [8] method is built upon two main prior works. Similarly to TIME [27], UCE operates by updating cross attention layers. As in MEMIT [25], UCE proposes a closed-form minimization over the covariance of the text embeddings representing the concepts being edited. Additionally to combining these methods, it explicitly models two sets of concepts corresponding to the set to be edited, and the set to be preserved. Thus, in order to erase a concept, the cross attention weights are modified so that the output for the concept's text embedding aligns with a different concept.

Reliable Concept Erasing (receler) [13] introduces lightweight "eraser" layers after each cross attention layers to remove the target concept from their output. Each lightweight "eraser" layer is composed by a pair or linear layers forming a bottleneck and an activation layer inbetween the two. The "eraser" layers are trained with Adversarial prompting (targeting to induce the model to generate images of the erased concept) and a form of concept-localized regularization. The regularization uses the attention masks related to the erase concept to identify the regions of the image that are most relevant to the target concept, and a binary mask that highlights the areas corresponding to the target concept.

Mass concept erasure (MACE) [23], similarly to UCE, refines the cross-attention layers of the pretrained model using a closed-form solution. Differently from the previous approach, it introduces an unique LoRA module [12] for each erased concept. The LoRA modules are trained to reduce the activation in the masked attention maps that correspond to the target concept. At this phase, a concept-focal importance sampling is introduced to mitigate the impact on unintended concepts by increasing the probability of the sampling smaller time steps, assumed to be closer to the selected concept. Finally, a closed-form solution is used to integrate multiple LoRA modules without mutual interference, leading to a final model that effectively forgets a wide array of concepts.

AdvUnlearn [47] formulates unlearning as an adversarial training process by formulating it as a bi-level optimization problem. The upper-level optimization aims to erase a specific concept from the diffusion model (same objective as the ESD [7] baseline), while the lower-level optimization generates adversarial prompts to attack the concepterased model. It also incorporates a utility-retaining regularization technique for addressing image quality retention. More specifically, uses a curated retain set of additional text prompts to help the model retain its image generation quality while ensuring that this set does not include prompts relevant to the concept being erased.

4.4. Experimental Setup

In our experiments, we use Stable Diffusion (SD) as the text-to-image model. We applied concept erasure techniques to each primary concept in the EraseBench dataset. For each concept, we erase a single target using both the default and reported best settings from the respective baseline papers. After erasing the target concept, we evaluate model behavior across related non-target concepts within the same

Table 1. Evaluation of Erasing concepts from EraseBench under the four different dimensions. We provide the average results across 10 concepts (for visual similarity (object), across 15 artists concepts (for artists similarity), 8 concepts for subset-superset, and 10 concepts (for binomial concepts). CLIP's zero-shot prediction along with the standard error mean (accuracies) are reported for each dimension in four sets: the erased concept (Eff., Efficacy), the paraphrase concepts (Gen., generality), the non-target visually similar concepts (Sens., sensitivity). The values presented are percentages (%). We provide more detailed results per concept in the Appendix. The classification accuracies of images generated by the original SD v1.4 are presented for reference.

	Visua	ll Similarity (O	bject)	Visual Sim	ilarity (Art)	Subset &	Super-set	Binomial

dimension in EraseBench, assessing the effects of erasure on visually or semantically similar concepts. Each concept in EraseBench is represented by over 10 unique prompts, which vary in length from short, simple phrases to more complex, descriptive ones. In order to capture the diverse outputs. We generate 10 distinct image samples per prompt by varying the random seed (total of 10 random seeds). This approach provides a comprehensive view of the erasure impact across different prompts and generations, enabling us to evaluate both the intended erasure and potential ripple effects on related concepts within the same dimension.

Figure 4. Erasure affects fine-grained alignment. Image generated for the prompt "A tiger perched on a rocky outcrop surrounded by mountains and a serene blue sky." before (left) and after (right) erasing the concept cat using MACE [23]). To measure the fine-grained alignment of concepts in complex prompts, we use the visual question answering framework Gecko with question-answers generated via Gemini 1.5.

4.5. Evaluation Metrics

We use three different automated evaluation metrics to quantify the post erasure performance: CLIP [29], Rich Automatic Human Feedback (RAHF [21]), and Gecko [39]. We leverage CLIP [29] as a zero-shot classifier to determine whether a model generates the desired concept. RAHF [21] provides aesthetic and artifact score, with higher numbers denoting better aesthetics and lesser artifacts. RAHF can also provide region proposals containing artifacts in an image. Finally, we use Gecko [39] as a visual question answering based evaluation framework, with a Gemini 1.5 model to both generate the questions in the first step, and answer them for given images in the second step.

5. Results and Discussion

5.1. Concept Erasure Reduces T2I Alignment

Table 1 presents the zero-shot predictions from CLIP as percentages (%). Following the definitions in [23], we measure two key attributes: Efficacy (Eff.) and Generality (Gen.). Efficacy represents the accuracy of concept erasure (accuracy on the erased class), where lower values indicate better erasure. Generality reflects accuracy on paraphrased or synonymous non-erased concepts, showing how well general information is erased. Additionally, we introduce Sensitivity (Sens.), defined as the accuracy for non-target but similar concepts. Most of the concept erasure techniques decreased accuracy on the target concept class (a desired outcome). Receler and AdvUnlearn achieved the best efficacy in erasure. Only a few techniques showed strong generality, indicating that erasure was not applied in a broad, global manner. In particular, Receler consistently displayed the best generality, preserving accuracy across target erased classes and paraphrased non-erased concepts. This may be attributed to the fact that Receler was trained using adversarial prompting and employs "erasers" designed to capture textual semantic concepts effectively. Overall, we ob-

Figure 5. Erasure introduces artifacts during similar concept generation. We erase concept "cat" and generate images for the prompt "an image of a cheetah". We present the RAHF artifact heatmaps for images generated post-erasure via UCE and MACE. We see that the artifact introduced by each method can vary spatially and by intensity, which prompts our inclusion of the artifact score in EraseBench.

served a decrease in sensitivity (a non-desired outcome). This exhibits a text-to-image misalignment for non-targetnon-erased concepts. There is noticeable misalignment between the text prompt and the generated image post erasure of the target concept. Low sensitivity suggests that generated images for similar, non-target concepts frequently fall out of distribution-indicating that the model has, in effect, "learned" to overlook related concepts indirectly rather than through direct erasure. This results in images that fail to align accurately with the intended text, underscoring the model's inability to fully retain non-target concepts after erasure is applied. In Figure 3 (row 1), we observe that when models undergo erasure of the "mouse" concept, prompting them with related concepts like "hamster" reveals unintended effect. These erased models appear to have also "forgotten" how to generate a hamster accurately (at least 4 out 5 techniques). This demonstrates a significant vulnerability in these erasure techniques, highlighting their limitations and the risks associated with deploying them in real-world, unrestricted settings. This trend of low sensitivity is consistent across dimensions of EraseBench. If we want evaluate overall, UCE has presented better sensitivity. Figure 4 shows an example of question answer pairs for a pair of an original and a sanitized image using Gecko [39]. While some aspects of the prompt are still correctly depicted in the image, the score is lower for sanitized model as it is missing the animal.

We compute alignment scores between images generated by original and sanitized models (UCE, MACE, and AdvUnlearn) and prompts corresponding to four different concepts (goat, goldfish, cat, and Vincent Van Gogh) from four different dimensions. In total, we compute alignment scores

Table 2. **Text-to-image alignment scores using Gecko metric.** The average scores and the standard error of the mean between prompts containing the erased and non-erased concepts and images generated with different sanitized models. Drop in score compared to the non-sanitized model shown in brackets.

Technique	Erased Concepts	Non-erased Concepts
Original	84.1 ± 0.9	77.6 ± 0.7
UCE [8]	$57.6 \pm 1.7 (-27.9)$	$74.3 \pm 0.8 (-4.9)$
MACE [23]	$38.2 \pm 1.3 (-47.4)$	$67.9 \pm 0.9 (-11.3)$
AdvUnlearn [47]	$43.1 \pm 1.4 (-28.0)$	$68.6 \pm 0.9 (-10.6)$

for 6246 text-image pairs. The results in Table 2 show an expected drop in scores for images generated with sanitized models compared to images generated with the original model (c.f. column "Erased concepts"), as we expect the erased concept to be missing in images generated by sanitized models. However, we also observe a drop in scores for non-erased concepts across different dimensions. While that drop is much smaller, it is statistically significant across all three comparisons ($\alpha = .01$ using the Wilcoxon signedrank test). The UCE technique has the smallest gap with the original model for non-erased concepts, while MACE has the largest. The results for UCE are consistent with CLIP-score zero-shot prediction in Table 1, where UCE was consistently the technique with highest sensitivity across all dimensions. Per-concept analysis revealed a statistically significant difference in scores between two groups in 2/5cases for UCE, 3/5 for MACE and 4/5 for AdvUnlearn $(\alpha = .01 \text{ using the Wilcoxon signed-rank test})$. We also manually inspected a subset of questions, answers and images, to ensure that the lower score is not caused by the VQA model latching on spurious correlations, but is indeed due to depicted concepts missing or the image being of lower quality. We observe that while some concepts are generally more difficult to depict correctly even in the original model (e.g. goldfish), this is reflected in the lower overall alignment score for the original model (e.g., for all three techniques the alignment score of the original model is in 60s for the concept goldfish, while it is in 80s and 90s for other concepts). But even in that case, Gecko is able to capture the drop in alignment for sanitized images.

5.2. Concept Erasure Reduces Quality For Retained Concepts.

Another important question emerges: what if the erased model retains similar non-target concepts? would this suggest that the model is unaffected by ripple effects? To explore this further, we examined the various dimensions of EraseBench. We specifically employed metrics that better align with human feedback, such as artifact measurements that quantify the degree of perceptible distortions and aesthetic quality—factors that reflect how humans perceive im-

Table 3. RAHF alignment scores [21].	Alignment scores for each c	oncept under the overall of	limension object similarity
	0	1	5

	Visual Similarity (Object)			Bind	omial	Subset of	f superset	
	Erase	"Cat"	Erase	"Goat"	Erase	"Lock"	Erase "C	Goldfish"

Original	87.71 ± 0.07	80.93 ± 0.02	83.23 ± 0.6	78.44 ± 0.2	85.23 ± 1.5	76.72 ± 0.8	84.15 ± 0.1	78.21 ± 0.3
UCE [8]	72.44 ± 0.9	73.77 ± 0.2	75.0 ± 1.0	74.19 ± 0.3	78.88 ± 3.4	78.5 ± 1.0	74.55 ± 0.6	72.20 ± 0.4
MACE [23]	73.5 ± 0.8	71.8 ± 0.07	72.0 ± 1.1	73.4 ± 1.2	72.79 ± 4.0	77.22 ± 0.7	72.64 ± 0.3	75.33 ± 0.2
AdvUnlearn [47]	74.6 ± 0.9	72.3 ± 1.2	69.78 ± 0.6	70.10 ± 0.9	66.23 ± 5.3	76.79 ± 1.1	71.87 ± 0.5	72.49 ± 0.2

age fidelity. In Table 3, we present the RAHF alignment scores of individual concepts under different dimensions of EraseBench. Our results reveal a significant decline in overall quality compared to the original SD, suggesting that even when non-target concepts are preserved, the erasure process still leads to noticeable degradation in image quality. This indicates that similar and related concepts remain vulnerable to generation flaws, despite attempts at concept retention. In Figure 3, we observe that most models capable of retaining and generating the intended concept after erasure still exhibit various types of distortions. These include misaligned body parts for animal classes, cropped concepts, nonsensical text distortions, decreased size of the generated concept, and a general lack of sharpness. Additional examples can be found in the Supplemental Material. What about concepts related to art? We observe a significant drop in text-to-image alignment, highlighting a major challenge in artistic style erasure as highlighted in Table 1. Similar styles or concepts across artists are at risk of being inadvertently erased if one artist's style is closely related to another. We observe this issue in the context of text-to-image alignment and found a marked degradation in quality, particularly in the style of non-target concepts. In Figure 3, we show the erasure of "Bosch" (the artist) and its impact on the ability to generate images of other artists, such as Altdorfer. Notably, we see a significant shift in style even for the non-erased concept. For this reason, we specifically chose not to use the RAHF alignment scores for artistic style, as the models were not trained to evaluate artistic style in line with their documentation.

5.3. Empirical Validation with Human Preferences

Figure 6. Human image preferences between images generated by the original and the erased model. The erased model used is UCE. Results show that humans prefer SD over UCE.

We conduct a human preference study to additionally val-

idate results and we obtained with automated evaluation techniques. We recruited 11 participants from our institution to judge images based on three different criteria: overall image quality, distortions, and text-to-image alignment. All participants were instructed on how to complete the task, and have provided consent to participate in the study. Each participant was presented with 50 side-by-side image comparisons, corresponding to 50 pairs of images generated by the original model and by the model with a concept erased. The order of images was randomized for each pair during presentation. The participants were asked the following three questions: (i) Which image exhibits superior overall quality? (ii) Which of the following images displays LESS noticeable distortions? (iii) Which image most accurately reflects and is aligned with the text label? Participants selected one of the three possible answers: Image A, Image B, Neutral. In total, we collected 1650 responses. We focus on images of non-erased concepts, as the primary hypothesis we wanted to test was whether non-target visually similar concepts were negatively affected with the erasure technique. We used UCE as it was overall the best performing technique on Sensitivity in Table 1 and also the model with the highest alignment score for non-erased concepts in Table 2. The results in Figure 6 show that humans judge images generated with the original model as having better overall quality and having fewer distortions. The original model is also preferred for better alignment, although it is closer to the "Neutral", meaning that either both the original and sanitized images were of equally good or equally poor quality. Overall, we find that human preferences corroborate findings we observe with automatic metrics.

6. Conclusion

This work presents a thorough evaluation of concept erasure techniques, uncovering shortcomings in their robustness and reliability. We introduce EraseBENCH, a comprehensive benchmark that reveals critical gaps in current methods, particularly when faced with visually similar, binomial, and semantically related concepts. Our findings demonstrate that despite recent advancements, existing techniques struggle to preserve model quality and ensure consistent erasure across a variety of scenarios. This highlights the need for more robust and nuanced approaches to concept erasure, as well as more rigorous evaluation protocols and metrics.

EraseBench: Understanding The Ripple Effects of Concept Erasure Techniques

Supplementary Material

We divide the supplemental material into the following sections: Section A details the prompt formulation used to leverage Large Language Models (LLMs) for identifying key entangled concepts, aiding in the systematic selection of challenging scenarios for concept erasure. Section B presents a global overview of the selected concepts included in EraseBench, categorized across various dimensions such as visual similarity, artistic style, binomial relationships, and subset-superset hierarchies. Section C includes sample prompts utilized to generate images with the text-to-image generative model, illustrating the diversity and specificity of inputs used for benchmarking. Section D provides additional quantitative results, presenting concept-wise metrics to supplement the core evaluation, offering deeper insights into erasure performance. Section E highlights qualitative examples, grounding the hypothesis of ripple effects observed post-erasure in entangled concepts, showcasing visual distortions and unintended consequences. Section F demonstrates post-erasure artifact heatmaps generated using the RAHF metric, offering a nuanced view of structural and stylistic distortions in the generated images. Section G concludes with an extended overview of existing concept erasure techniques, providing a comprehensive reference to the state of the art in the literature.

Identifying Concept Entanglement Prompt

Your main task is to help identify concepts for evaluating text-to-image models. The key idea is to identify four concepts that are se-

mantically entangled with the **Given Concept** and another three concepts that are paraphrased versions of it. Below is an example. Given Concept: cat

Paraphrase concepts: kitten, siamese, tabby Similar concepts: tiger, lion, cheetah, panther Now it is your turn.

Given concept:

A. Using LLMs to Identify Entangled Concepts

To compile a diverse set of entangled and related concepts, we utilized Large Language Models (LLMs) to identify key concepts that are likely to exhibit semantic entanglement within a model's representation space. By carefully crafting the main concepts, we prompted the LLM to generate

Table 4. EraseBench concepts designed for evaluating visual similarity within the object dimension. This showcases a diverse selection of target and related concepts that emphasize nuanced variations in appearance, structure, and context to effectively test semantic entanglement and concept erasure capabilities

Main concept	Paraphrase	Similar

Table 6. EraseBench concepts tailored to binomial relationships. This focus on pairs of interrelated concepts to assess the model's handling of semantic dependencies and the impact of concept erasure on closely linked representations.

Main concept	Similar
Cat	Dog
Needle	Thread
Lock	Key
Sun	Moon
Camera	Film
Cup	Saucer
Pen	Pencil

following prompt:

This distinction ensures a nuanced and robust dataset for evaluating the entanglement dynamics in text-to-image models.

B. Selected Concepts for EraseBench

Tables 4, 5, 6, 7 provide more details of the concepts used for each dimension of EraseBench. The tables below pro-

vide a comprehensive summary of the primary concepts and the associated entangled concepts that were carefully considered during the evaluation. EraseBench evaluates concepts that share a high degree of visual similarity. These concepts are chosen to explore how erasure techniques handle subtle distinctions and overlaps between visually similar objects. The tables below highlight the primary concepts to erase, along with closely related concepts to evaluate on that exhibit entanglement, challenging the robustness of concept erasure methods.

C. Example Prompts from EraseBench

We present below some examples of the prompts used to generate images from concepts for EraseBench, with the aim of capturing a diverse range of image generations. For each concept, we vary key elements such as the length of the text prompt and the style (e.g., "a photo of," "a painting of," etc.). This approach ensures a broad exploration of concept representations across different contexts.

Text Prompts Examples for Concept "Cat" Paraphrase

- A cat.
- An image of a cat.
- A cat playing in a pile of autumn leaves with vibrant reds oranges and yellows all around.
- A kitten.
- An image of a kitten.
- A kitten lounging in a cozy tea garden surrounded by cherry blossom trees.
- A tabby.
- An image of a tabby.
- A majestic tabby with bright green eyes sitting near a window gazing a full moon.
- A siamese.
- An image of a siamese.
- A brave British shorthair curled up on a warm windowsill.
- A tiger.
- An image of a tiger.
- A tiger perched on a rocky outcrop surrounded by mountains and a serene blue sky.

The primary goal is to more effectively identify and analyze failure modes arising from entanglement across various dimensions within the EraseBench framework, enhancing our understanding of how these interactions impact model performance.

Text Prompts Examples for Concept "Cat" Similar

- A tiger.
- An image of a tiger.
- A tiger perched on a rocky outcrop surrounded by mountains and a serene blue sky.
- A cheetah.
- An image of a cheetah.
- A cheetah prowling through a moonlit rainforest with glowing eyes reflecting the light and tropical foliage all around.
- A lynx.
- An image of a lynx.
- A lynx stealthily moving through a lush green jungle with dampled sunlight filtering through the leaves.
- A panther.
- An image of a panther.
- A majestic panther drinking from a crystal-clear pool its reflection shimmering on the water's surface framed by vibrant jungle flora.

Table 7. EraseBench concepts for the subset-superset relationships. This can show how specific concepts are related to broader categories or more specialized instances. This set of concepts evaluates the model's ability to distinguish and erase concepts that exist within hierarchical relationships, ensuring effective handling of concept granularity and scope during erasure tasks.

Main concept	Similar
Latte	Espresso
	Cappuccino
Crocodile	Alligator
	Lizard
Cocker Spaniel	Golden Retriever
	Poodle
Ukelele	Acoustic Guitar
	Violin
Goldfish	Guppy
	Clownfish
Emerald	Diamond
	Violin
Ice cream	Popsicle
	Sundae
Humming bird	Wood Pecker
-	Sparrow
Lemon	Lime
	Orange

D. Additional Quantitative Results

In Tables 8, 9 and 10, we present the CLIP zero-shot accuracies for each concept individually, as well as for their corresponding similar and paraphrased concepts, across different dimensions of concept entanglements—namely, visual similarity (object), binomial relationships, artistic similarity, and subset-superset relations. Our observations are as follows:

• Effectiveness of Erasure Techniques: Techniques like Re-

celer, MACE, and AdvUnlearn demonstrate greater robustness in erasing targeted concepts. These methods yield a significant decrease in accuracy, which aligns with the intended outcome of the efficacy metric.

- Generalization to Paraphrased Concepts: When it comes to paraphrased (synonymous) concepts, models like Receler and AdvUnlearn show strong generalization. These techniques, which are heavily reliant on adversarial text training, not only erase the target concepts effectively but also handle paraphrased concepts with high efficiency.
- Challenges with weight perturbation techniques: On the other hand, weight perturbation methods like UCE struggle to efficiently erase target concepts. Moreover, UCE also demonstrates weaker generalization when erasing paraphrased concepts, indicating a limitation in its erasure capabilities compared to adversarial-based techniques.
- Sensitivity to Non-Target Concepts: In terms of sensitivity, defined as the ability to avoid erasing similar,techniques like Receler and AdvUnlearn experience a notable performance drop. This results in a substantial decrease in sensitivity, which is undesirable. In contrast, UCE performs slightly better in terms of sensitivity, likely because it does not rely as heavily on adversarial training, thus retaining a better balance in preserving similar nontarget concepts.

These findings suggest that while adversarial-based techniques excel in erasing target and paraphrased concepts, they may introduce unwanted degradation in sensitivity. Weight perturbation methods like UCE, while less effective at erasing target concepts, maintain better sensitivity, presenting a trade-off between erasure strength and unintended concept interference.

As for concepts unrelated to the target erased concepts (e.g., erasing the concept "cat" and considering "hot air balloon" as the unrelated target), we observe that these methods have little to no effect when it comes to erasing nonentangled concepts. This contrasts with their impact on entangled concepts, where the erasure techniques demonstrate more significant effects. The absence of a noticeable change in unrelated concepts highlights the specificity of these methods and their vulnerability on entangled concepts.

E. Additional Qualitative Results

In figure 7, we illustrate examples of distortions observed in entangled concepts following erasure, along with their impact on performance. Notably, methods such as Receler and MACE exhibit a tendency to entirely forget non-erased but entangled concepts. For instance, erasing the concept "goat" results in a complete erasure of the related concept "ibex." On the other hand, while other techniques manage to retain the "ibex" concept, the images generated post-erasure

Table 8. **CLIP zero-shot prediction accuracies** are reported for the subset of superset dimension in EraseBench: the erased concept (evaluating the efficacy of erasure) and the non-target similar concepts (reflecting the sensitivity of erasure). The results reveal a significant degradation in sensitivity, particularly in scenarios where concept entanglement occurs, highlighting challenges in effectively disentangling related concepts during erasure.

exhibit significant structural distortions. These include alterations in the size of the concept (either enlargement or shrinkage), noticeable blurriness, and overall degradation of image quality, emphasizing the challenges of maintaining fidelity while achieving effective erasure.

Figure 8 highlights the impact of concept entanglement during the erasure of artistic styles and artists with overlapping creative characteristics. For instance, when the concept "Claude Monet" is erased, prompting the model to generate works in the style of "Camille Pissarro" reveals a substantial degradation in Pissarro's distinctive artistic voice, as though it has been unintentionally muted. Similarly, erasing "Wassily Kandinsky" from the model and prompting it to replicate "Kazimir Malevich's" style, rooted in abstract and geometric form, exposes ripple effects across all evaluated concept erasure techniques. The model not only forgets the geometric essence of Malevich's style but also compromises the representation of similar traits in non-erased artists, demonstrating the broader challenges posed by entangled concept erasure. We also provide additional qualitative results for both EraseBench dimensions: Binomial and Subset of superset in Figures 9 and 10.

F. Post-Erasure Artifact Heatmaps

Figures 11, 12, 13, 15, 14, and 16 illustrate the RAHF artifact heatmaps, highlighting the artifacts introduced by

concept erasure techniques both post-erasure and in the entangled, similar concepts. These artifacts exhibit significant variability in terms of size and intensity, presenting challenges for traditional metrics like CLIP scores, which are often insufficient to fully capture these nuanced distortions. Consequently, metrics such as the artifact score and aesthetic score offer a more holistic evaluation, providing deeper insights into the quality and integrity of the generated images under the defined entanglement scenarios.

G. Existing Concept Erasure Techniques

Concept erasure has been explored through a range of techniques, each employing unique methodologies tailored to different challenges in removing specific concepts while retaining overall model utility. These approaches can be broadly categorized into fine-tuning, textual inversion, and more advanced frameworks such as continual learning strategies. Fine-tuning methods are particularly prominent. Techniques like Erased Stable Diffusion (ESD) [A1] finetune the diffusion model's U-Net to steer its generative outputs away from the target concept. Textual inversion techniques, on the other hand, focus on modifying the latent textual representations. These methods, like Textual Inversion (CI) [A2], learn new word embeddings for specific concepts by leveraging fine-tuned diffusion models. This enables precise mapping of concepts in the latent space while retain-

ing the flexibility of text-to-image generation. In addition, continual learning-inspired methods like Selective Amnesia (SA) [A3] frame concept erasure as a dual objective:

forgetting the undesired concept while preserving performance on retained data. By integrating ideas from Elastic Weight Consolidation (EWC) and Generative Replay, SA

penalizes changes in critical weights and employs surrogate likelihoods to ensure robust erasure without compromising unrelated data. Model-Based Ablation [A4] for concept erasure has also shown to be effective. The idea is to fine-tune the model to align the target's representation with the anchor's, and add a Noise-Based Ablation, which redefines training pairs to associate the target concept's prompt with anchor images. These refine specific components, like cross-attention layers or full U-Net weights, ensuring the target concept is effectively overwritten.

In our work, we narrowed down existing techniques and focused on leveraging more recent, advanced and diverse approaches to concept erasure, experimenting with recent techniques that incorporate variations such as fine-tuning model weights (e.g. ESD), introducing targeted weight perturbations (e.g. UCE), and refining textual embeddings and adversarial training (e.g. Receler, AdvUnlearn), and introducing parameter efficient fine-tuning (Receler, MACE). Table 9. **CLIP zero-shot prediction accuracies** are reported for the visual similarity (objects) dimension in EraseBench: the erased concept (evaluating the efficacy of erasure), the paraphrased concepts (demonstrating the generality of erasure), the non-target visually similar concepts (reflecting the sensitivity of erasure), and the non-target unrelated concepts (indicating the specificity of erasure). The results reveal a significant degradation in sensitivity, particularly in scenarios where concept entanglement occurs, highlighting challenges in effectively disentangling related concepts during erasure.

Figure 11. Erasure introduces artifacts during similar concept generation. We erase concept "seal" and generate images for the prompt "an image of a manatee". We present the RAHF artifact heatmaps for images generated post-erasure via UCE and AdvUnlearn. We see that the artifact introduced by each method can vary spatially and by intensity, which prompts our inclusion of the artifact score in EraseBench.

This allowed us to explore the nuanced dynamics of concept erasure and assess its impact under different dimensions.

Figure 12. Erasure introduces artifacts during similar concept generation. We erase concept "koala" and generate images for the prompt "an image of a tree kangaroo". We present the RAHF artifact heatmaps for images generated post-erasure via AdvUnlearn and MACE. We see that the artifact introduced by each method can vary spatially and by intensity, which prompts our inclusion of the artifact score in EraseBench.

Figure 13. Erasure introduces artifacts during subsetof superset concept generation. We erase concept "lemon" and generate images for the prompt "an image of an orange". We present the RAHF artifact heatmaps for images generated post-erasure via AdvUnlearn and ESD. We see that the artifact introduced by each method can vary spatially and by intensity, which prompts our inclusion of the artifact score in EraseBench.

Figure 14. Erasure introduces artifacts during binomial concept generation. We erase concept "sun" and generate images for the prompt "an image of a moon". We present the RAHF artifact heatmaps for images generated post-erasure via AdvUnlearn and UCE. We see that the artifact introduced by each method can vary spatially and by intensity, which prompts our inclusion of the artifact score in EraseBench.
