#### Abstract

Mitigation of biases, such as language models' reliance on gender stereotypes, is a crucial endeavor required for the creation of reliable and useful language technology. The crucial aspect of debiasing is to ensure that the models preserve their versatile capabilities, including their ability to solve language tasks and equitably represent various genders. To address this issue, we introduce streamlined *Dual Dabiasing Algorithm through Model Adaptation* (*2DAMA*). Novel *Dual Debiasing* enables robust reduction of stereotypical bias while preserving desired factual gender information encoded by language models. We show that *2DAMA* effectively reduces gender bias in English and is one of the first approaches facilitating the mitigation of stereotypical tendencies in translation. The proposed method's key advantage is the preservation of factual gender cues, which are useful in a wide range of natural language processing tasks.

#### 1 Introduction

Gender representation in large language models (LLMs) has been the topic of significant research effort [\(Stanczak and Augenstein,](#page-14-0) [2021;](#page-14-0) [Kotek](#page-12-0) [et al.,](#page-12-0) [2023\)](#page-12-0). Past studies have predominantly focused on such representation to identify and mitigate social biases. Admittedly, biases are a challenging issue limiting the reliability of LLMs in real-world applications. Yet, we argue that preserving particular types of gender representation is crucial for fairness and knowledge acquisition in language models.

To provide a more detailed perspective, we draw examples of both unwanted and beneficial types of gender signals in LLMs. Undesirable biases are typically inherited from stereotypes and imbalances in the training corpora and tend to be further amplified during the model training [\(Van Der Wal](#page-14-1)

<span id="page-0-0"></span>

Figure 1: Dual character of gender signals encoded in language models: stereotypical cues are shown on the left, and factual gender cues are shown on the right-hand side. "*Die Ärztin*" and "*der Arzt*" are respectively female and male German translation for "*the doctor*".

[et al.,](#page-14-1) [2022;](#page-14-1) [Gallegos et al.,](#page-12-1) [2024\)](#page-12-1). Biases are manifested in multiple ways, including unequal representation (models are more likely to generate mentions of a specific overrepresented gender), stereotypical associations (particular contexts are associated with one gender based on stereotypical cues, e.g., "*politics and business are male domains*", while "*family is a female domain*"). It has been shown that, due to bias, LLMs struggle with highstakes decision-making and are prone to produce discriminatory predictions. Examples of such a sensitive application are the automatic evaluation of CVs and biographical notes [\(De-Arteaga et al.,](#page-10-0) [2019\)](#page-10-0), where some professions are stereotypically associated with a specific gender. Therefore, individuals of that gender could benefit from unfair advantage when assessed by an LLM-based evaluator.

Nevertheless, LLMs should understand and represent gender signals. For instance, chatbots should be persistent in addressing the user with their preferred gender pronouns after they are re-vealed (Limisiewicz and Mareček, [2022\)](#page-13-0). Adequate representation of gender is also required for knowledge acquisition, for example, in question answering (QA), to correctly answer "*Maria Skłodowska-Curie*" to the question "*Who was the first woman to win a Nobel Prize?*". Gender sensitivity is even more critical in morphologically rich languages, where gender mentions are much more ubiquitous, e.g., through morphological markings (as in German, Czech, or Russian) [\(Hellinger and](#page-12-2) [Bußmann,](#page-12-2) [2002\)](#page-12-2). Examples of dual characters of gender encoding are shown in Figure [1.](#page-0-0)

## 1.1 Solution

To address these intricate ways gender signals are present in natural language, we introduce a new method *2DAMA* that post-hoc modifies pre-trained language models to represent gender in an equitable way, i.e., without stereotypical bias but with factual gender information. The approach leverages recent effective methods for model adaptation [Limisiewicz et al.](#page-13-1) [\(2024\)](#page-13-1); [Meng et al.](#page-13-2) [\(2022\)](#page-13-2), and concept erasure [Belrose et al.](#page-10-1) [\(2023\)](#page-10-1). As the core contribution, we introduce the novel method of *Dual Debiasing* that aims at our core problem of decreasing bias while keeping equitable factual gender representation.

We present a strong theoretical backing of the effectiveness of our new method *2DAMA* in Section [2.](#page-1-0) Subsequently, we show the experimental approach in the results for applying the method to the aforementioned case of gender: stereotypical vs. factual (Sections [3,](#page-3-0) [4\)](#page-6-0). Furthermore, we are the first to mitigate LLMs' multilingual gender bias manifested in translation from English to three morphologically rich languages, presented in Section [5.](#page-7-0)

### 1.2 Research Questions

In the experimental part, we present an extensive analysis of the observed patterns in gender representation in four models and the effect of different design choices in the debiasing approach. The analysis specifically answers the research questions, grouped into four areas:

- A. How extensive the update of parameters should be to erase gender bias? Can the extent of the update be implicitly learned by the debiasing method?
- B. To what extent, after debiasing, can we preserve model performance in both genderrelated and other tasks?
- C. What are the similarities and differences in the distribution of two analyzed signals (bias and factual gender) in models' weights?
- D. Does *2DAMA* generalize to other languages? Is the distribution of bias signal in a model shared across distinct languages?

Upon publication of the work, we will release the code and instances of debiasd models.

## <span id="page-1-0"></span>2 Methodology and Theoretical Background

In this section, we introduce *Dual Debaising Algorithm through Model Adaptation* (*2DAMA*), a new dual debiasing method. We first describe the *2DAMA*'s intended function, i.e., how it should alter the pre-trained language model, and describe the algorithmic components that efficiently fulfill these aims. Then, we provide theoretical backing for the presented approach. Appendix [A](#page-15-0) contains the proofs and further terminological explanations.

#### 2.1 Motivations for 2DAMA

The key idea of debiasing through model adaptation is that we can perform a targeted and efficient parameter change in a model to erase the unwanted signals encoded in it. The main risk of such an approach is that erasing bias can also affect the encoded knowledge.

We can draw a specific example of such a tradeoff from gender debiasing. We aim to reduce the models' reliance on stereotypes in predictions, e.g., given a stereotypical prompt as the one in Figure [2a:](#page-4-0) "*The salesperson laughed because*", we intend to coerce equitable probabilities of possible gender predictions manifested by pronouns "*he*", "she", or "them". On the contrary, when considering a prompt containing factual gender information: "*The king laughed because*" the desired output distribution would assign a high probability to the male pronoun.

We call the issue mentioned above *Dual Debiasing* problem. *2DAMA* is designed to alter language models to reduce their reliance on stereotypes while maintaining sensitivity to factual gender.

#### 2.2 Composing 2DAMA Approach

In practice, *2DAMA* leverage on the combination of new (*Dual Debiasing*) and previously introduced algorithms (*DAMA*, *LEACE*). We shortly describe each of *2DAMA*'s components and the role they fulfill:

DAMA *Debiasing Algorithm through Model Adaptation* [\(Limisiewicz et al.,](#page-13-1) [2024\)](#page-13-1) is a method for adapting parameters of language models to mitigate the encoding of harmful biases without affecting their general performance. The method employs model editing techniques [\(Meng et al.,](#page-13-2) [2022\)](#page-13-2) to disassociate specific signals provided in a prompt with the model outputs, i.e., stereotypes in prompts and gendered output. In this work, we use most of *DAMA* design choices, such as the adaptation of mid-upper feed-forward layers and algorithm to distill the stereotypical and gender-related parts of the latent representation (as depicted in Figure [2\)](#page-4-0).

LEACE *LEAst-squares Concept Erarsuer* [\(Bel](#page-10-1)[rose et al.,](#page-10-1) [2023\)](#page-10-1) is a method of concept erasure (such as bias signal) in latent representation. In Section [2.3,](#page-2-0) we show that combining *DAMA* and *LEACE* is possible and simplifies model adaptation. The simplification is obtained by replacing the Partial Least Squares concept erasure used in *DAMA*, which required pre-defining the dimensionality of erased signals. Moreover, in Section [4,](#page-6-0) we show that *DAMA* with *LEACE* obtain comparable or better results.

2D *Dual Debiasing* is a new algorithm that we formally introduce in Section [2.4.](#page-3-1) The method uses covariance matrix decomposition to identify correlates related to bias and protected feature signals. A concept erasure algorithm (based on *LEACE*) is modified to erase bias while preserving protected features, in our case, factual gender.

#### <span id="page-2-0"></span>2.3 Model Adaptation with LEACE

*LEACE* provides guarantees of erasing specific variable (concept  $Z$ ) influence on another random variable (signal  $X$ ). In the language of neural networks, we can consider latent vectors output by an intermediate layer as a sample drawn from the distribution given by X. *LEACE* aims to de-correlate latent vectors with an unwanted signal (e.g., gender bias), whose distribution is represented as another random vector Z.

<span id="page-2-3"></span>Theorem 1 (LEACE). *We consider random vectors* X *and* Z *taking values in* R n *. Both random vectors are centered, each with a finite moment.*

*Then the objective:*

$$
\mathop{\arg\min}\limits_{\boldsymbol{P}\in\mathbb{R}^{n\times n}}\mathbb{E}\left[||\boldsymbol{P}X-X||^2\right]
$$

*subject to:*

$$
\mathbb{C}\mathrm{ov}(\boldsymbol{P} X,Z)=0
$$

*is solved by:*

$$
P^* = \mathbb{I} - W^{\dagger} P_{W\Sigma} W,
$$

*where* W *is the whitening transformation*  $(\Sigma_{V,V}^{1/2})^{\dagger}$ ;  $P_{W\Sigma}$  *is an orthogonal projection* matrix onto colspace of  $\boldsymbol{W}\boldsymbol{\Sigma}_{V,Z}.$   $^1$  $^1$ 

The proof can be found in [Belrose et al.](#page-10-1) [\(2023\)](#page-10-1). We extend this theoretical finding to erase the concept in linear transformations instead of latent vectors. We are specifically interested in transformation minimizing the error between input (keys:  $U$ ) and predicted variable (values:  $V$ ), as depicted in Figure [2b.](#page-4-0) We reasonably assume that dense layers of trained neural networks (e.g., feed-forward layers in Transformer) fulfill this purpose, i.e.:

$$
V = SU - \epsilon, \tag{1}
$$

where S is a linear transformation and  $\epsilon$  a vector of errors. Due to gradient optimization in the model's pre-training, we assume that the feedforward layer approximates the least solution, i.e.,  $FF \approx S$ .

Taking this assumption, we can present a theorem guaranteeing concept erasure in the model adaptation algorithm (*DAMA*):

<span id="page-2-2"></span>Theorem 2 (DAMA-LEACE). *We consider ran*dom vectors: U taking values in  $\mathbb{R}^m$ , V and Z tak- $\lim_{n \to \infty}$  values in  $\mathbb{R}^n$ , where  $m \geq n$ . Under assump*tions that: A) random vectors*  $U, V, Z$  *are centered, and each of them has finite moment; B) the regression relation between* U *and* V *fulfill the assumption of ordinary least squares, and there exist least squares estimator*  $V = SU - \epsilon$ *.* 

*Then the objective:*

$$
\underset{\boldsymbol{P} \in \mathbb{R}}{\arg \min } \mathbb{E} \left[ ||\boldsymbol{P} U - V||^2 \right],
$$

*subject to:*

$$
\operatorname{Cov}(\boldsymbol{P} U, Z) = 0
$$

<span id="page-2-1"></span> $1$ Notation:  $\dot{+}$  denotes Moonrose-Penrose psuedoinverse. For brevity, we use  $\Sigma_{V,Z}$  for covariance matrix  $\mathbb{C}\text{ov}(V, Z)$ . The complete terminological note can be found in Appendix [A](#page-15-0)

*is solved by:*

$$
\pmb P^* = \left( \mathbb{I} \, {-} \pmb W^\perp \pmb P_{\pmb W \pmb \Sigma} \pmb W \right) \pmb S,
$$

*where* W *is the whitening transformation*  $(\Sigma_{\text{SU,SU}}^{1/2})^{\ddagger}$ ;  $P_{\text{W}\Sigma}$  is an orthogonal projection *matrix onto colspace of*  $W\Sigma_{SU,Z}$ *;* S is a least  $squares$  estimator of  $V$  given  $U$ :  $\boldsymbol{S} = \boldsymbol{\Sigma}_{U,V} \boldsymbol{\Sigma}_{U,U}^{-1}$ .

Based on the theorem and the assumption that  $FF \approx S$  applying projections would break the correlation between stereotypical keys and gendered values with minimal impact on other correlations stored by the feed-forward layer. We call the algorithm realizing such adaptation in a neural network: *DAMA*-*LEACE*. [2](#page-3-2)

### <span id="page-3-1"></span>2.4 Dual Debiasing

In *Dual Debiasing*, we extend the concept erasure problem by considering two type signals and corresponding random variables:  $Z_b$  bias to be erased and  $Z_f$  feature to be preserved. We posit that:

<span id="page-3-3"></span>Theorem 3 (DUAL-DEBIASING). *We consider random vectors*  $X$ *,*  $Z_b$ *, and*  $Z_f$  *in*  $\mathbb{R}^n$ *. Under the assumptions that: A)*  $Z_b$  *and*  $Z_f$   $Z_b$   $\perp$   $Z_f$ |X, *i.e.*,  $Z_b$  *and*  $Z_f$  *are conditionally independent, given*  $(X; B)$   $\Sigma_{X,Z_b}\Sigma_{X,Z_f}^T$ , *i.e., the variable* X *is correlated with*  $Z_f$  *and*  $\dot{Z}_b$  *through mutually orthogonal* subspaces of  $\mathbb{R}^n$ . The solution of the objective:

$$
\underset{\boldsymbol{P}\in\mathbb{R}^{n\times n}}{\arg\min}\mathbb{E}\left[||\boldsymbol{P}X-X||^2\right],
$$

*subject to:*

$$
\mathbb{C}\mathrm{ov}(\boldsymbol{P} X,Z_b)=0,
$$

*satisfies:*

$$
Cov(PX, Z_f) = Cov(X, Z_f).
$$

The theorem shows that the correlation with the conditionally independent features is left intact by applying *LEACE* erasure to a bias signal. However, the assumption of conditional independence is strong and unlikely to hold when considering the actual signals encoded in the model. Thus, for practical applications, we need to relax the requirements.

In *Dual Debiasing*, we abandon theoretical guarantees of the theorem to consider bias and feature signals that can be conditionally correlated. In constructing the debiasing projection  $(P*)$ , we must decide whether specific dimensions should be nullified or preserved. We propose to nullify dimensions of  $X$  with  $t$  times higher correlation with  $Z_f$  than  $Z_b$ , where the threshold t (later referred to as *bias-to-feature threshold*) is empirically chosen. To analyze the correlations we consider correlation matrix  $W\Sigma_{X,[Z_f,Z_b]}$ . By using singular value decomposition, we can identify the share of variance in each column's first  $n$  rows (associated with  $Z_f$ ) and the latter n rows (associated with  $Z_b$ ). In modified colspace projection  $P_{W\Sigma}$ , we only consider the column with t times higher variance with  $Z_f$  than with  $Z_b$ . Thus the final *Dual Debiasing LEACE* projection  $\tilde{P}^*$  =  $(\mathbb{I} - W^{\dagger} \tilde{P}_{W\Sigma} W)$  will to large extent preserve the protected feature while reliably erasing bias. In Section [4.2,](#page-7-1) we study the impact of feature-tobias threshold  $t$  in practice.

#### <span id="page-3-0"></span>3 Experimental Setting

This section presents an empirical setting to examine the practical application of model editing methods. Specifically, we describe models, data, and evaluation metrics for gender bias and general performance.

#### 3.1 Models

In experiments, we focus on Llama family models [\(Touvron et al.,](#page-14-2) [2023;](#page-14-2) [Dubey et al.,](#page-10-2) [2024\)](#page-10-2), which are robust and publically available language models developed by Meta AI. We analyze Llama 2 models of sizes 7 and 13 billion parameters and Llama 3 with 8 billion parameters. In multilingual experiments, we use ALMA-R 13 billion parameter model [\(Xu et al.,](#page-14-3) [2024\)](#page-14-3). ALMA-R is based on an instance of the Llama 2 model that was fine-tuned to translate using Contrastive Preference Optimization. ALMA-R covers translation between English and five languages (German, Czech, Russian, Icelandic, and Chinese) and shows competitive translation quality results.

In model editing experiments, we adapt the layers starting from the one found in the two-thirds of the layer stack counted from the input to the output. It is the 26th layer for 13 billion parameter models and the 21st layer for smaller models. For example, the adaptation of 11 mid-upper lay-

<span id="page-3-2"></span> $2^2$ Noteworthy, [Belrose et al.](#page-10-1) [\(2023\)](#page-10-1) also proposed using *LEACE* to alter language model predictions. Yet they applied the algorithm to latent representation instead of altering model parameters as in *DAMA*-*LEACE*.

<span id="page-4-0"></span>

Figure 2: Schema (b) shows *DAMA* intervention in a language model layer. (a) We show the model's behavior when presented with a stereotypical prompt in three languages. Specifically, (c) shows the projections of the feed-forward latent vector  $(\vec{u})$  onto the output space. With *DAMA* (lower arrow), we nullify the gender component of the representation. It results in balanced probabilities of gendered tokens in the model's output, as shown in (d). Adapted from [Limisiewicz et al.](#page-13-1) [\(2024\)](#page-13-1).

ers in the 13B model modifies the layers from 26th through 37th.

## 3.2 Data for Dual Debiasing

Following [Limisiewicz et al.](#page-13-1) [\(2024\)](#page-13-1), we feed prompts to the model in order to obtain the latent embeddings in the input of latent layers. We treat these embeddings as key vectors  $(U)$  containing stereotypical or factual gender signals. To obtain the gendered value vectors  $(V)$ , we find the layer's output vector that would maximize the probability of predicting tokens corresponding to gender.

Language Modeling Prompts For debiasing language models, we use solely English prompts. We design 11 prompt templates, such as "*The X laughed because* \_\_\_", where "X" should be replaced by profession name. This prompt construction provokes the model to predict one of the gendered pronouns ("*he*", "*she*", or "*them*"). To distinguish stereotypical signals for debiasing, we use 219 professions without factual gender that were annotated as stereotypically associated with one of the genders by [Bolukbasi et al.](#page-10-3) [\(2016\)](#page-10-3).

Multilingual Prompts For debiasing machine translation, we use prompts instructing the model to translate sentences containing the same set of 219 professions to a target language that has the grammatical marking of gender, e.g., "*English: The X is there. German: \_\_\_*". The translation

model would naturally predict one of the German determiners, which denotes gender ("*Der*" for male or "*Die*" for female). For each model, we adjust the template to include instructions suggested by the model's authors. We construct the translation prompts for two target languages, Czech and German, proposing 11 templates for each.

Factual Prompts *Dual debiasing* requires using factual prompts to identify the signal to be preserved. For that purpose, we use the same prompt templates as defined above (both English and multilingual) with the distinction of entities used to populate them. For that purpose, we propose 13 pairs of factually male and female entities, e.g., "*king*" – "*queen*", "*chairman*" – "*chairwoman*".

The examples of language modeling and multilingual prompts are given in Figure [2a.](#page-4-0) We list all of the prompt templates in Appendix [B](#page-17-0)

## 3.3 Bias Evaluation

Language Modeling We assess the bias in language generation following the methodology of [Limisiewicz et al.](#page-13-1) [\(2024\)](#page-13-1). From the dataset of [Bolukbasi et al.](#page-10-3) [\(2016\)](#page-10-3), we select the held-out set of professions that were not included in the 219 used for debiasing. Each profession was assigned two scores: *factual* score  $x_f$  and *stereotypical* score  $x_s$ . The scores define how strongly a word (or a prompt) is connected with the male or female gender, respectively, through factual or stereotypi-

<span id="page-5-0"></span>

		Bias in LM		WinoBias		
	$\downarrow a_s$	$\uparrow a_f$	$\downarrow b$	$\downarrow \Delta S$	$\downarrow \Delta G$	
Llama 2.7B	0.234	0.311	0.090	33.6	7.3	
<b>DAMA</b>	0.144	0.205	0.032	27.3	6.8	
DAMA+LEACE	0.118	0.171	0.028	22.9	5.4	
2DAMA	0.128	0.187	0.042	22.9	5.7	
Llama 2 13B	0.244	0.322	0.097	35.0	0.3	
<b>DAMA</b>	0.099	0.160	0.030	26.4	2.4	
DAMA+LEACE	0.098	0.159	0.026	26.5	2.4	
2DAMA	0.119	0.206	0.023	27.0	1.9	
Llama 3 8B	0.262	0.333	0.082	36.8	2.7	
<b>DAMA</b>	0.069	0.090	0.144	20.3	4.2	
DAMA+LEACE	0.084	0.157	0.082	18.8	2.7	
2DAMA	0.140	0.209	0.051	18.7	2.4	

Table 1: Bias evaluation for the Llama family models, and their adaptation with different debiasing algorithms (*DAMA*, *DAMA* with *LEACE*, and *2DAMA*). The debiasing adaptation was applied to 12 mid-upper layers for the 13B model and 9 midupper layers for the smaller ones. In *2DAMA*, we set bias-to-feature threshold to  $t = 0.05$ .

cal cues. By convention, scores range from −1 for female-associated words to 1 for male ones. We measure the probabilities for gendered prediction for a given prompt  $P_M(o|X)$ . For that purpose, we use pronouns  $o_+$  = "he" and  $o_-$  = "she", as they are probable continuations for given prompts. Subsequently for each prompt, we compute *empirical* score  $y = P_M(o_+|X) - P_M(o_-|X)$ . To estimate the relationship between the observed score and annotated ones  $x_s$  and  $x_f$ , we construct a linear model:

$$
y = a_s \cdot x_s + a_f \cdot x_f + b_0 \tag{2}
$$

The linear fit coefficients have the following interpretations:  $a<sub>s</sub>$  is an impact of stereotypical signal on the model's predictions;  $a_f$  is an impact of the factual gender of the word. Noticeably,  $y, x_s$ , and  $x_f$  take the values in the same range. The slope coefficient tells how shifts in annotated scores across professions impact the difference in prediction probabilities of male and female pronouns. The intercept  $b_0$  measures how much more probable the male pronouns are than the female pronouns when we marginalize the subject.

Other Bias Manifestations in English We evaluate the bias in coreference resolution based on WinoBias dataset [\(Zhao et al.,](#page-14-4) [2018\)](#page-14-4). We use metrics  $\Delta G$  and  $\Delta S$  to evaluate representational

<span id="page-5-1"></span>

	LM	ARC	
	$\downarrow$ ppl	$\uparrow$ acc (C)	$\uparrow$ acc (E)
Llama 27 <sub>B</sub>	21.28	70.2	42.5
<b>DAMA</b>	21.51	69.8	42.8

Llama 3 8B		67.1	39.9
<b>DAMA</b>		64.6	38.1
DAMA+LEACE		63.0	39.8
2DAMA		63.5	37.9

Table 2: General performance in language modeling and reasoning on ARC Chalange and Easy subset. We present results for Llama family models, and their adaptation with different debiasing algorithms (*DAMA*, *DAMA* with *LEACE*, and *2DAMA*). We do not present perplexity for Llama 3 because the model has different vocabulary and the results are not comparable. The hyperparameters are the same as in Table [1](#page-5-0)

and stereotypical bias, respectively.  $\Delta G$  measures the difference in coreference identification correctness (accuracy) between masculine and feminine entities; similarly,  $\Delta S$  measures the difference in accuracy between pro-stereotypical and anti-stereotypical instances of gender role assignments.

Translation [\(Stanovsky et al.,](#page-14-5) [2019\)](#page-14-5) proposed using Winograd Challenge sentences for evaluating bias in translation from English into eight languages with morphological marking of gender (e.g., German, Spanish, Russian, Hebrew). In WinoMT, the correctness of the translation is computed by the F1 score of correctly generating gender inflection of profession words in the target language. The evaluation of gender bias is analogical, as in WinoBias.  $\Delta G$  and  $\Delta S$  measure the difference in F1 scores: male vs. female and provs. anti-stereotypical sets of professions, respectively. The more recent BUG [\(Levy et al.,](#page-12-3) [2021\)](#page-12-3) dataset is based on the same principle of bias evaluation, with the distinction that it contains naturally occurring sentences instead of generic templates used in WinoMT.

<span id="page-6-2"></span>

Figure 3: Visualization of dimensions and their variances related to stereotypical and factual gender signals identified by *Dual Debiasing* algorithm in 26th layer of Llama 2 13B. The red dots denote the bias-to-feature threshold  $t = 0.05$ . In 2DAMA, the dimension is preserved if stereotypical covariance is below the threshold.

#### 3.4 General Performance Evaluation

Language Modeling We evaluate perplexity on general domain texts from Wikipedia-103 corpus [\(Merity et al.,](#page-13-3) [2016\)](#page-13-3).

Reasoning Endtask To assess the models' reasoning capabilities, we compute accuracy on AI2 Reasoning Challenge (ARC) [\(Clark et al.,](#page-10-4) [2018\)](#page-10-4) in both easy and challenging subsets.

Translation To monitor the effect of debiasing on translation quality, we evaluate models on WMT-22 [\(Kocmi et al.,](#page-12-4) [2020\)](#page-12-4) parallel corpora with German, Czech, and Russian sentences and their translations in English. We estimate the quality by two automatic metrics: COMET-22 [\(Rei](#page-13-4) [et al.,](#page-13-4)  $2022$ ) and chrf (Popović,  $2015$ ).

### <span id="page-6-0"></span>4 Debiasing Language Models

In the first batch of the experiments, we evaluate the effectiveness of debiasing language models with model editing. In these experiments, we solely focus on tasks in English. We specifically analyze three model editing approaches: *DAMA* as a baseline; *DAMA* in combination with *LEACE*; and *2DAMA*, which employs *Dual Debiasing* to preserve factual gender information.

#### 4.1 Main Results

Model editing reduces bias and preserves the model's performance. All of the considered methods reduce gender bias both in language modeling and coreference resolution (Table [1\)](#page-5-0). Remarkably, we observe that the model's overall performance, i.e., unrelated to gender, is not significantly affected, as demonstrated by perplexity and question-answering results (Table [2\)](#page-5-1). Relatively worse performance preservation was observed for

<span id="page-6-3"></span>

Table 3: Number of erased and preserved orthogonal dimensions with *2DAMA* in each feedforward layer. We call a dimension "*biased*" when it belongs to col-space spanned by covariance matrix between latent representation and bias signal  $(W\Sigma_{SU,Z})$ . We present the percentage of erased covariance with stereotypical bias and factual gender as the result of the intervention in the layers. The bias-to-feature threshold was set at  $t = 0.05$ .

Llama 3, which could be caused by intervening in too many layers.

Streamlining the approach with *LEACE*. We observe that *DAMA*-*LEACE* reduces bias to a larger extent than baseline *DAMA*. The more substantial debiasing effect comes in pair with a slightly higher drop in general performance, as shown in Table [2.](#page-5-1) Yet, the deterioration is still insignificant compared to the original models' scores. The crucial benefit of *DAMA*-*LEACE* is that projection dimensionality does not need to be pre-defined because it is learned implicitly (details in Section [2.3\)](#page-2-0). [3](#page-6-1) That motivates us to use *DAMA*-*LEACE* in further experiments.

Preserving factual gender with *Dual Debiasing*. The coefficients  $a_s$  and  $a_f$  from Table [1](#page-5-0) indicate how much the models' prediction is affected by gender present through stereotypical and factual cues, respectively. We see that *2DAMA* enables, to a significant extent, preserving factual gender information with a slight increase in susceptibility to gender bias.

<span id="page-6-1"></span><sup>&</sup>lt;sup>3</sup>In baseline *DAMA*, the projection dimensionality is preset to  $d = 256$  for the 7B model and  $d = 512$  for the 13B models.

<span id="page-7-2"></span>

Figure 4: The hyperparameter analysis for *2DAMA* applied to Llama 2 13B model on performance and bias in language modeling. We measured bias on gendered prompts by linear coefficients:  $a_s$  and  $a_f$ , the language modeling capabilities are measured by perplexity. Stars mark the performance of the best setting. The dashed line corresponds to the scores of the original model.

In the remainder of this Section, we describe the relationship between stereotype and factual gender encoding in the model and the role of parameter choice in *2DAMA*.

## <span id="page-7-1"></span>4.2 Relationship between Seterotypical and Factual Signals

With *Dual Debiasing*, we can analyze the covariance of the latent orthogonal dimensions in the model's feed-forward layers with the stereotypical and factual signals (as detailed in Section [2.4\)](#page-3-1). In Figure [3,](#page-6-2) we plot these covariances for each dimension. The visualization reveals that the factual gender is represented by relatively few dimensions with high covariance. In contrast, stereotypical bias is encoded in more-dimensional subspaces, yet each dimension has low covariance.

In Table [3,](#page-6-3) we demonstrate that in *2DAMA* with low bias-to-feature threshold  $t = 0.05$  preserves only a few dimensions responsible for stereotypical bias in each layer. Such intervention in the model erases  $\approx 99\%$  of covariance with a stereotypical signal while keeping over 30% of covariance with a factual gender signal.

## <span id="page-7-3"></span>4.3 Choice of Hyperparameters

We present the impact of two parameters on the effectiveness of *2DAMA* in Figure [4.](#page-7-2) The first is the bias-to-feature threshold  $t$ . We observe that its choice controls the trade-off between mitigating bias and preserving factual information. We set it a low value of 0.05 because our primary objective is the reduction of bias. The second hyperparameter is the number of layers that should be edited. We confirm the findings of [Limisiewicz et al.](#page-13-1) [\(2024\)](#page-13-1) that adaptation should applied to approximately one-third of the midd-upper layers. Notably, the top two layers (38th and 39th) should be left out.

## <span id="page-7-0"></span>5 Beyond English: Multilingual Debiasing

In a multilingual setting, we debias a model finetuned for translation: ALMA-R 13B [\(Xu et al.,](#page-14-3) [2024\)](#page-14-3) by employing the collection of the new multilingual debiasing prompts. We specifically focus on gender bias and quality of translation between English and Czech, German, and Russian.

### 5.1 Main Results

Model editing generalizes to the multilingual settings. Analogically to experiments in English, we show that model editing reduces bias in translation and has a mediocre impact on the translation quality (as shown in Table [4\)](#page-8-0). We observe some differences in results between the two analyzed languages. Overall, the scores after debiasing are better for German than Czech, indicating that German prompts are better quality.

*Dual Debiasing* is required to mitigate representational bias. Our methods are more effective for the stereotypical manifestation of bias  $\Delta S$ than the representational one  $\Delta G$ . In the representational bias, we sometimes observe bias increase after model editing. To remedy that, we use *2DAMA* with higher values of feature-to-bias threshold ( $t = 1.00$  instead of  $t = 0.05$ ), which tends to preserve more factual signal. Factual gen-

<span id="page-8-0"></span>

		comet	$\uparrow$ chrf	$\uparrow$ comet	$\uparrow$ chrf	$\downarrow \Delta S$	$\downarrow \Delta G$	$\downarrow \Delta S$	$\downarrow \Delta G$
	ALMA-R 13B	85.0	57.0	86.7	58.1	30.5	3.7	7.8	32.5
	DAMA+LEACE	85.0	56.7	85.3	55.4	20.5	10.0	5.4	33.6
German	2DAMA $(t = 0.05)$	84.9	56.7	85.1	54.8	22.6	3.3	4.4	27.8
	2DAMA $(t = 1.00)$	84.9	56.6	85.4	55.4	22.1	$-10.1$	7.7	28.4
	ALMA-R 13B	87.0	68.6	89.7	53.8	26.3	2.1	11.7	9.2
	DAMA+LEACE	86.9	68.2	88.6	50.1	21.6	17.7	10.4	18.0
Czech	2DAMA $(t = 0.05)$	86.9	68.1	88.5	49.9	18.0	14.6	4.5	11.0
	2DAMA $(t = 1.00)$	86.9	68.1	88.8	50.4	22.4	7.2	8.6	9.8

Table 4: Evaluation of gender bias and quality of translation. In all the methods, ALMA-R was used as the base model. Adaptations were applied to 11 mid-upper feed-forward layers. Translation quality was evaluated on the WMT-22 dataset.

<span id="page-8-1"></span>

(a) Representational bias  $(\Delta G)$ 

(b) Stereotypical bias  $(\Delta S)$ 

Table 5: Bias evaluation based on WinoMT challenge-set. The evaluation language is shown at the top of each column. Each row corresponds to a set of languages for which prompts were used in model adaptation. The debiasing adaptation was performed with *2DAMA* on 11 mid-upper layers with the biasto-feature threshold set to  $t = 0.05$ .

der understanding is especially essential for equitable representation of factual gender in morphologically rich languages, as evidenced by  $\Delta G$ scores for  $t = 1.00$  setting. This finding emphasizes the utility of *2DAMA* in a multilingual setting.

The extended study of hyperparameters in translation debiasing is presented in Appendix [C.](#page-17-1)

## 5.2 Cross-lingual Debiasing

An intriguing question of multilingual bias is whether its encoding is shared across languages [\(Gonen et al.,](#page-12-5) [2022\)](#page-12-5). We test this hypothesis by editing models with prompts in one or multiple languages and testing on another language. The results show evidence of effectiveness in crosslingual mitigation of stereotypical gender bias. In Table [5b,](#page-8-1) we observe that some languages are more effective in debiasing than others, e.g., German prompts offer the strongest  $\Delta S$  reduction for both Czech and German. Whereas to control representational bias mitigation  $(\Delta G)$ , it is recommended to use in-language prompts, as indicated by Czech, German, and Russian results in Table [5a.](#page-8-1)

## 6 Related Work

We refer to the related work grouped into three areas.

## 6.1 Model Editing and Concept Erasure

Model editing is a method of applying targeted changes to the parameters of the models to modify information encoded in them. Notable examples of model editing include targeted changes in the model's weight [\(Mitchell et al.,](#page-13-6) [2022;](#page-13-6) [Meng](#page-13-7) [et al.,](#page-13-7) [2023,](#page-13-7) [2022\)](#page-13-2) or adaptation with added modules (adapters) [\(Houlsby et al.,](#page-12-6) [2019;](#page-12-6) [Hu et al.,](#page-12-7) [2022\)](#page-12-7). The technique showed promising results as the tool to erase specific information [\(Patil et al.,](#page-13-8) [2024\)](#page-13-8).

In the literature, bias mitigation was perceived as a theoretically interesting and practical application for concept erasure. [Ravfogel et al.](#page-13-9) [\(2020,](#page-13-9) [2022\)](#page-13-10); [Belrose et al.](#page-10-1) [\(2023\)](#page-10-1) proposed effective linear methods of erasing gender bias from the latent representation of language models. Other approaches aimed to edit pre-trained language models to reduce their reliance on stereotypes. They include: causal intervention [\(Vig et al.,](#page-14-6) [2020\)](#page-14-6), model adapters [\(Fu et al.,](#page-12-8) [2022\)](#page-12-8), or targeted weight editing [\(Limisiewicz et al.,](#page-13-1) [2024\)](#page-13-1). As the name indicates, *2DAMA* primarily builds on the last method.

#### 6.2 Debiasing Machine Translation

Machine translation systems have been shown to exhibit gender bias in their predictions [\(Savoldi](#page-13-11) [et al.,](#page-13-11) [2021\)](#page-13-11). The problem is especially severe in translation from languages that do not grammatically mark gender (e.g., English, Finish) to ones that do (e.g., German, Czech, Spanish) because translation requires predicting gender, which is not indicated in the reference [\(Stanovsky et al.,](#page-14-5) [2019\)](#page-14-5). There have been a few past attempts to mitigate biases in translation systems [\(Saunders and Byrne,](#page-13-12) [2020;](#page-13-12) [Iluz et al.,](#page-12-9) [2023;](#page-12-9) [Zmigrod et al.,](#page-14-7) [2019\)](#page-14-7). Nevertheless, these approaches are based on finetuning for non-stereotypical sentences, which increases the model's specialization but significantly reduces usability, e.g., in tasks unrelated to gender [\(Luo et al.,](#page-13-13) [2023\)](#page-13-13).

One key constraint of multilingual debiasing is the scarcity of bias annotations in various languages. Notable datasets were introduced by [Levy](#page-12-3) [et al.](#page-12-3) [\(2021\)](#page-12-3); [Névéol et al.](#page-13-14) [\(2022\)](#page-13-14). The difficulty of obtaining reliable cross-lingual bias resources stems from the need for deep knowledge of culture in addition to understanding a language. For instance, in different cultures, the same mentions tend to be associated with distinct sets of stereotypes: the word "*doctor*" in English is strongly associated with the male gender due to the overrepresentation of men in this profession in the US and the UK. While in many Slavic and Baltic languages, the "*doctor*"s are to a lesser extent biased or even associated with the female gender, due to the higher proportion of women in medical profes-sions.<sup>[4](#page-9-0)</sup>

To the best of our knowledge, we are the first to propose a method for debiasing LLM in machine translation tasks.

#### 6.3 Controlled Debiasing

Sound practice in model debiasing involves carefully monitoring performance in bias-unrelated tasks and diverse manifestations of bias. The former aspect is needed for the reliability and usefulness of the models after debiasing. The latter's importance is highlighted by the observations that different bias metrics are mutually weakly or even negatively correlated [\(Delobelle et al.,](#page-10-5) [2022;](#page-10-5) [van der Wal et al.,](#page-14-8) [2024\)](#page-14-8), raising the need for holistic evaluation. The aspect of preserving useful features correlated with bias is especially underresearched. A noteworthy study of interactions between factual gender and gender bias was con-ducted by Limisiewicz and Mareček [\(2022\)](#page-13-0). To our knowledge, we are the first to show that keeping factual gender can help mitigate diverse types of bias.

#### 7 Disussion and Conclusion

We highlight the importance of considering the dual character of gender encoding in model editing. Our theoretical and empirical results show that the novel model editing methods: *2DAMA* effectively reduces the impact of stereotypical bias on the predictions while preserving equitable representation of (factual) gender based on grammar and semantics. Maintaining the factual component of gender representation is crucial for debiasing in languages other than English, which denote gender more ubiquitously. Furthermore, our method does not significantly deteriorate the high performance of LLMs in various evaluation settings unrelated to gender.

To answer the research questions. The results show that novel *2DAMA* is an effective debiasing method that can implicitly learn the extent (dimensionality) of bias signals (re: A). Thus, it is easier to apply to new models. Specifically, we do not require setting the number of erased bias dimensions in latent space thanks to changing the underlying erasure to *LEACE*. Furthermore, our method has minimal impact on gender-unrelated tasks (re: B), and thanks to *Dual Debiasing*, it can also identify and preserve factual signals, even though it is significantly correlated with bias (re: C). Lastly, we show that *2DAMA* can be applied to a multilingual setting, and we observe the evidence of bias sharing across languages (re: D).

<span id="page-9-0"></span> $4$ According to [OECD](#page-13-15) [\(2023\)](#page-13-15): in 2021, women made up over 70% of medical doctor numbers in Lithuania, Latvia, and Estonia, while only 36% in the US .

## <span id="page-15-0"></span>A Proofs

## A.1 Terminological Note

For brevity of theorems and proofs, we adopt the following notation convention:

Definition 1 (Moore-Penrose Pseudoinvers). *We denote Moore-Penrose pseudoinverse of matrix*  $M$  *as*  $M^+$ :

$$
\boldsymbol{M}^{\dot{+}}=(\boldsymbol{M}^T\boldsymbol{M})^{-1}\boldsymbol{M}^T
$$

Definition 2 (Matrix Square Root). *We denote a positive semi-definite square root of positive semi*definite matrix  $M$  as  $M^{1/2}$ .

Definition 3 (Covariance Matrix). *For two random vectors:*  $X \in \mathbb{R}^m$  *and*  $Y \in \mathbb{R}^n$ *. We denote the covariance matrix as:*

$$
\Sigma_{X,Y} = \mathbb{C}\mathrm{ov}(X,Y)
$$

#### A.2 Proof for DAMA-LEACE Theorem

We formalize the requirements and implications of that assumption in the following theorem:

<span id="page-15-1"></span>Theorem 4 (Gauss-Markov: Probabilistic Least Squares). *We consider random vectors:* U *taking values in* R <sup>m</sup>*,* V *, and* Z *taking values in*  $\mathbb{R}^n$ ; both are centered and have finite second mo*ments. We seek the linear regression model given by:*

$$
V = \mathbf{S}U - \epsilon,
$$

*given the following assumptions:*

- *A No Multicollinearity: there is no linear relationship among the independent variables, i.e., matrix*  $\Sigma_{U|U}$  *is of full rank m.*
- *B Exogeneity: the expected value of error terms given independent variables*  $\mathbb{E}[\epsilon|U] =$ 0*, this also implies that*  $\mathbb{C}ov(\epsilon, U) = 0$ *.*
- *C Homoscedasticity: the covariance of the error terms is constant and does not depend on the independent variables*  $\mathbb{C}ov(\epsilon, \epsilon | U) = \sigma \mathbb{I}$ .

*Then, the ordinary least squares estimator is given by the formula:*

$$
\boldsymbol{S}^* = \boldsymbol{\Sigma}_{U,V}\boldsymbol{\Sigma}_{U,U}^{-1}
$$

*Such estimator is best linear unbiased estimator and minimizes the variance of error terms:*  $Tr(\mathbb{C}ov(\epsilon, \epsilon)).$ 

The proof of the Theorem [4](#page-15-1) can be found in the classical statistics literature. For instance, [Eaton](#page-12-10) [\(1983\)](#page-12-10) presents proof for the multivariate case presented above.

Equipped with the theorems above, we are ready to present the theorem that is the main theoretical contribution of this work:

Theorem [2.](#page-2-2) *We consider random vectors:* U *tak*ing values in  $\mathbb{R}^m$ , *V* and *Z* taking values in  $\mathbb{R}^n$ , where  $m \geq n$ . Under assumptions that: A) ran*dom vectors* U*,* V *,* Z *are centered, and each of them has finite moment; B) the regression relation between* U *and* V *fulfill the assumption of ordinary least squares, and there exist least squares estimator*  $V = SU - \epsilon$ *.* 

*Then the objective:*

$$
\underset{\boldsymbol{P} \in \mathbb{R}}{\arg \min } \mathbb{E} \left[ ||\boldsymbol{P} U - V||^2 \right],
$$

*subject to:*

$$
Cov(\mathbf{P}U,Z)=0
$$

*is solved by:*

$$
\boldsymbol{P}^* = \left( \mathbb{I} \, {-} \boldsymbol{W}^\top \boldsymbol{P}_{\boldsymbol{W}\boldsymbol{\Sigma}} \boldsymbol{W} \right) \boldsymbol{S},
$$

*where* W *is the whitening transformation*  $(\Sigma_{SU, SU}^{1/2})^{\dagger}$ ;  $P_{W\Sigma}$  *is an orthogonal projection matrix onto colspace of*  $W\Sigma_{SU,Z}$ *; S is a least squares estimator of*  $V$  *given*  $U$ *:*  $\dot{\mathbf{S}} = \mathbf{\Sigma}_{U,V} \mathbf{\Sigma}_{U,U}^{-1}$ .

*Proof.* For simplicity, we will decompose the problem into independent optimization objectives corresponding to each dimension in  $\mathbb{R}^n$ . For the ith dimension, we write the objective as:

<span id="page-15-2"></span>
$$
\underset{\mathbf{P}_i \in \mathbb{R}^n}{\arg \min} \mathbb{E} \left[ \mathbf{P}_i^T V - V_i \right]^2 \quad \text{s.t.} \quad \mathbb{C}\text{ov}(\mathbf{P}_i U, Z) = 0,
$$
\n(3)

where  $P_i$  is *i*th column of matrix  $P$ . From the assumption (B) of the theorem, we can represent the linear relation between U and V, as  $SU = V +$  $\epsilon$ , where  $\epsilon$  is an error term of regression. We use this property to rewrite the minimization objective from expression [3,](#page-15-2) as:

<span id="page-15-3"></span>
$$
\underset{\widetilde{\boldsymbol{P}_i} \in \mathbb{R}^n, \boldsymbol{S} \in \mathbb{R}^{m \times n}}{\arg \min} \mathbb{E} \left[ \widetilde{\boldsymbol{P}_i}^T \boldsymbol{S} U - V_i \right]^2 \tag{4}
$$

We manipulate the term under arg min to rewrite it as a sum of three terms:

$$
\mathbb{E}\left[\widetilde{\boldsymbol{P}_i}^T \boldsymbol{S} U - V_i\right]^2 = \mathbb{E}\left[\widetilde{\boldsymbol{P}_i}^T (V + \epsilon) - V_i\right]^2 =
$$
\n
$$
= \mathbb{E}\left[\widetilde{\boldsymbol{P}_i}^T (V + \epsilon) - (V_i + \epsilon_i) + \epsilon_i\right]^2 =
$$
\n
$$
= 2E\left[\left(\widetilde{\boldsymbol{P}_i}^T (V + \epsilon) - (V_i + \epsilon_i)\right)\epsilon_i\right] +
$$
\n
$$
+ \mathbb{E}[\epsilon_i]^2 + \mathbb{E}\left[\widetilde{\boldsymbol{P}_i}^T (V + \epsilon) - (V_i + \epsilon_i)\right]^2
$$
\n
$$
\mathbb{II}\tag{5}
$$

We will now consider each of the three summands one by one to find the solution to the optimization objective  $P^* = \tilde{P}^* S^*$ .

Summand I zeros out. We show that by observ-ing that the summand is doubled covariance<sup>[5](#page-16-0)</sup>:

$$
E\left[\left(\widetilde{P}_i^T(V+\epsilon) - (V_i + \epsilon_i)\right)\epsilon_i\right] =
$$
  
=  $\mathbb{C}\text{ov}\left(\widetilde{P}_i^T(V+\epsilon) - (V_i + \epsilon_i), \epsilon_i\right) =$   
=  $\left(\widetilde{P}_i^T - \mathbb{1}_i^T\right)\mathbb{C}\text{ov}(V-\epsilon, \epsilon) =$   
=  $\left(\widetilde{P}_i^T - \mathbb{1}_i^T\right)\mathbf{S}\mathbb{C}\text{ov}(U, \epsilon)$  (6)

From assumption B of Theorem [4](#page-15-1) (exogeneity) and, by extension, assumption of this theorem, we have that  $\text{Cov}(U, \epsilon) = 0$  and thus summand I zeros out.

Summand II by the conclusion of Theorem [4](#page-15-1) is minimized by setting:

$$
S^* = \Sigma_{U,V} \Sigma_{U,U}^{-1} \tag{7}
$$

We can also set  $S$  to  $S^*$  in summand III, as the variable under  $E$  is independent of  $\epsilon$ , as shown in the previous paragraph. By finding  $S^*$ , we have solved part of the objective in expression [4.](#page-15-3)

**Summand III** we find the matrix  $\overrightarrow{P}$  minimizing the value of the summand under constraines. By rewriting  $\mathbb{C}\text{ov}(P_iU)$ , Z) as  $\mathbb{C}\text{ov}(\widetilde{P_i}(V+\epsilon, Z))$ , we observe that minimizing the value of summand III under constraint is analogical to solving the problem stated in LEACE (Theorem [1\)](#page-2-3):

$$
\argmin_{\widetilde{P}_i \in \mathbb{R}^n} \mathbb{E} \left[ \widetilde{P}_i^T (V + \epsilon) - (V_i + \epsilon) \right]^2
$$
\n
$$
\text{such that } \operatorname{Cov}(\widetilde{P}_i (V + \epsilon), Z) = 0
$$
\n(8)

We find the solution based on Theorem [1,](#page-2-3) where we substitute X with  $V + \epsilon$  and find  $\widetilde{P}^* = \mathbb{I} - W^+ P_{W\Sigma} W$ , where W is the whitening transformation  $(\Sigma_{V+\epsilon,V+\epsilon}^{1/2})^+$ ;  $P_{W\Sigma}$  is an orthogonal projection matrix onto colspace of  $W\Sigma_{V+\epsilon,Z}$ 

Conclusion for summands II and III, we independently found the matrices minimizing their values. We obtain the matrix  $P^*$  solving our original objective in expression [3](#page-15-2) by multiplying them:

$$
P^* = \widetilde{P}^* S^* = \left(\mathbb{I} - W^{\dagger} P_{W\Sigma} W\right) \Sigma_{U,V} \Sigma_{U,U}^{-1}
$$
\n(9)

#### A.3 Proof for Dual-Debiasing Theorem

**Theorem [3.](#page-3-3)** We consider random vectors  $X$ ,  $Z_b$ , and  $Z_f$  in  $\mathbb{R}^n$ . Under the assumptions that: A)  $Z_b$ and  $Z_f Z_b \perp Z_f | X$ , *i.e.*,  $Z_b$  *and*  $Z_f$  *are conditionally independent, given*  $X$ ;  $B$ )  $\Sigma_{X,Z_b}\Sigma_{X,Z_f}^T$ , *i.e., the variable X is correlated with*  $Z_f$  *and*  $Z_b$  through mutually orthogonal subspaces of  $\mathbb{R}^n$ . *The solution of the objective:*

$$
\underset{\boldsymbol{P}\in\mathbb{R}^{n\times n}}{\arg\min}\mathbb{E}\left[||\boldsymbol{P}X-X||^2\right],
$$

*subject to:*

$$
\mathbb{C}\mathrm{ov}(\boldsymbol{P} X,Z_b)=0,
$$

*satisfies:*

$$
\mathbb{C}\mathrm{ov}(\boldsymbol{P} X, Z_f) = \mathbb{C}\mathrm{ov}(X, Z_f).
$$

*Proof.* First, we observe that the assumption A) can be generalized to any coordinate system. For an orthogonal matrix  $W$ , we have:

$$
\Sigma_{\boldsymbol{W}X,Z_b}\Sigma_{\boldsymbol{W}X,Z_f}^T = \boldsymbol{W}\Sigma_{X,Z_b}\Sigma_{X,Z_f}^T\boldsymbol{W}^T = 0
$$
\n(10)

This guarantees the orthogonality of spaces spanned by columns of two orthogonality matrices. The property will be useful for the second part of the proof:

<span id="page-16-1"></span>
$$
Col(\mathbf{\Sigma_{W}}_{X,Z_b}) \perp Col(\mathbf{\Sigma_{W}}_{X,Z_f}) \qquad (11)
$$

Secondly, we remind the reader that the solution to the objective provided in the theorem (based on Theorem [1\)](#page-2-3) is as follows:

$$
P^* = \mathbb{I} - W^{\dagger} P_{W\Sigma} W \tag{12}
$$

<span id="page-16-0"></span><sup>&</sup>lt;sup>5</sup> From the fact that both factors under  $E$  are centered.

Now, we evaluate the covariance matrix between  $P^*X$  and  $Z_f$  to check that it is the same as the covariance matrix between X and  $Z_f$ .

<span id="page-17-2"></span>
$$
\mathbb{C}\text{ov}(\boldsymbol{P}^*X, Z_f) = \boldsymbol{\Sigma}_{X, Z_f} - \boldsymbol{W}^{\perp} \boldsymbol{P}_{\boldsymbol{W}\boldsymbol{\Sigma}} \boldsymbol{W} \boldsymbol{\Sigma}_{X, Z_f} = \\ = \boldsymbol{\Sigma}_{X, Z_f} - \boldsymbol{W}^{\perp} \boldsymbol{P}_{\boldsymbol{W}\boldsymbol{\Sigma}} \boldsymbol{\Sigma}_{\boldsymbol{W} X, Z_f} \\ (13)
$$

we note that  $P_{W\Sigma}$  is the projection matrix onto the column space of  $\Sigma_{WX,Z_f}$ . From that fact and Equation [11,](#page-16-1) we have:

$$
P_{W\Sigma} \Sigma_{WX, Z_f} = 0 \tag{14}
$$

Thus the last component in Equation [13](#page-17-2) nullifies and we conclude that:

$$
\mathbb{C}\mathrm{ov}(\boldsymbol{P}^*X, Z_f) = \boldsymbol{\Sigma}_{X, Z_f} = \mathbb{C}\mathrm{ov}(X, Z_f) \quad (15)
$$

#### <span id="page-17-0"></span>B Prompts

#### B.1 Monolingual Prompts

The list of 11 prompt templates is given in Ta-ble [6.](#page-17-3) The term <profession> is substituted by 219 professions without factual gender (from [Boluk](#page-10-3)[basi et al.,](#page-10-3) [2016\)](#page-10-3) and 2[6](#page-17-4) gendered entities,  $6$  which makes 2409 stereotypical and 286 factual prompts in total used for *Dual Debiasing*.

#### B.2 Multilingual Prompts

For debiasing the translation models, we use 11 English-German and 11 English-Czech prompt templates shown in Table [7.](#page-18-0) These prompts were designed to be as general as possible, and so that the target language prefix does not include any gender information, while the proposed completions, which are always one-token words, do specify the gender. In German, these completions may be determiners. Czech does not use determiners, but gender is included, for example, in the past form of the verb "to be". We use the same sets of professions, and therefore, we generate additional data of equal size for each language. To match the

intended use, we wrap them into ALMA-R translation prompt template:

Translate this from {src\_lang} to {tgt\_lang}: {src\_lang}: <English source> {tgt\_lang}: <Target prefix>

<span id="page-17-3"></span>

Table 6: Monolingual English prompt templates.

### <span id="page-17-1"></span>C Additional Results

## C.1 Stereotypical and Factual Signals across Layers

In Figure [6,](#page-19-0) we observe the variances with stereotypical and factual gender signals in subsequent layers. We see that the number of biased dimensions differs across layers. Nevertheless, we observe the same pattern in each layer: stereotypical signal is encoded in a relatively small number of dimensions with high variance, while the stereotypical variance is spread across more dimensions with lower values in each.

## C.2 Choice of Hyperparameters in Translation

Analogically to Section [4.3,](#page-7-3) we present the impact of bias-to-feature threshold  $t$  and the number of edited layers on translation to German in Figure [5.](#page-18-1) We observe that stronger factual regularization (high  $t$ ) helps in reducing representational bias  $(\Delta G)$  yet offers weaker stereotypical bias mitigation ( $\Delta S$ ). Similar to the results in language modeling, the best performance is obtained when editing 12 mid-upper layers with  $t = 0.05$ .

<span id="page-17-4"></span><sup>6</sup> "*man*", "*boy*", "*gentleman*", "*father*", "*son*", "*brother*", "*husband*", "*king*", "*prince*", "*uncle*", "*nephew*", "*groom*", "*duke*", "*grandfather*", "*widower*", "*hero*", "*wizard*", "*baron*", "*emperor*", "*anchorman*", "*clergyman*", "*chairman*", "*alumnus*", "*woman*", "*girl*", "*lady*", "*mother*", "*daughter*", "*sister*", "*wife*", "*queen*", "*princess*", "*aunt*", "*niece*", "*bride*", "*duchess*", "*grandmother*", "*widow*", "*heroine*", "*witch*", "*baroness*", "*empress*", "*anchorwoman*", "*clergywomen*", "*chairwomen*", "*alumna*"

<span id="page-18-1"></span>

Figure 5: The hyperparameter analysis for *2DAMA* applied to ALMA-R 13B model on performance and bias in translation to German. We measured bias via WinoMT metrics ∆S and ∆G. The translation quality to Germna is measured by chrf on WMT-22. Stars mark the performance of the best setting. The dashed line corresponds to the scores of the original model.
