

# Mean and Variance Estimation Complexity in Arbitrary Distributions via Wasserstein Minimization \*

Valentio Iverson<sup>†</sup>      Stephen A. Vavasis<sup>‡</sup>

January 20, 2025

## Abstract

Parameter estimation is a fundamental challenge in machine learning, crucial for tasks such as neural network weight fitting and Bayesian inference. This paper focuses on the complexity of estimating translation  $\boldsymbol{\mu} \in \mathbb{R}^l$  and shrinkage  $\sigma \in \mathbb{R}_{++}$  parameters for a distribution of the form  $\frac{1}{\sigma^l} f_0\left(\frac{\boldsymbol{x}-\boldsymbol{\mu}}{\sigma}\right)$ , where  $f_0$  is a known density in  $\mathbb{R}^l$  given  $n$  samples. We highlight that while the problem is NP-hard for Maximum Likelihood Estimation (MLE), it is possible to obtain  $\varepsilon$ -approximations for arbitrary  $\varepsilon > 0$  within  $\text{poly}\left(\frac{1}{\varepsilon}\right)$  time using the Wasserstein distance.

## 1 Introduction

A fundamental challenge in machine learning is the estimation of distribution parameters. For instance, in neural networks, estimating the parameters of the model to fit into distribution that underlies the weights can significantly impact model performance. Accurate parameter estimation is also crucial in other area like Bayesian inference, where it affects the choice of prior and posterior distributions.

Recently, modern machine learning methods have increasingly leveraged optimal transport-based distances due to their ability to robustly compare probability measures [AGL+20] [CMZ+19] [IGG+24]. Optimal transport has emerged as a versatile framework for addressing a range of machine learning problems, such as image generation [WLX+23], image restoration [AOEM24] and generative modeling [KFL22] [RKB22]. This motivates us to revisit classical mean and variance estimation methods, such as maximum likelihood estimation (MLE) within the Expectation-Maximization (EM) algorithm [EH21], and explore the advantages of utilizing optimal transport metrics, particularly the minimization of the Wasserstein distance [FZM+15].

This paper focuses on the complexity of estimating translation and shrinkage parameters, specifically  $\boldsymbol{\mu} \in \mathbb{R}^l$  and  $\sigma \in \mathbb{R}_{++}$ , for a class of distributions that are piecewise constant over a finite number of disjoint hyperrectangles. These distributions are expressed as  $\frac{1}{\sigma^l} f_0\left(\frac{\boldsymbol{x}-\boldsymbol{\mu}}{\sigma}\right)$ , where  $f_0$  is a known density function in  $\mathbb{R}^l$ . In this framework,  $\boldsymbol{\mu}$  denotes the translation parameter, and  $\sigma$  controls the scaling of the distribution. The goal is to estimate these parameters from  $n$  samples such that the resulting distribution closely aligns with the samples, a key objective in generative modeling tasks.

We select this specific class of distribution because it allows us to carry out the complexity-theoretic analysis outlined in this paper. Specifically, we require a class of distribution that is both finitely specifiable and universal in some sense, as detailed later in Claim 2.6.

This problem is particularly significant in the context of the Expectation-Maximization (EM) algorithm [DLR77], especially within the Maximization step. The EM algorithm’s variants have been extensively explored, including modifications like those discussed in the Sinkhorn EM algorithm [MNVNW21]. Our study emphasizes the complexity of parameter estimation by comparing Maximum Likelihood Estimation (MLE) with Wasserstein distance approaches. While MLE poses NP-completeness challenges for certain class of distributions, our use of the Wasserstein distance offers a polynomial-time approximation for estimating  $\mu$  and  $\sigma$ . Though our algorithm may not be computationally practical for large-scale optimization, it effectively demonstrates the main result of achieving polynomial-time complexity.

Further supporting this approach, studies like [KRH18] on the Sliced Wasserstein Distance for Gaussian Mixture Models underline the value of Wasserstein metrics in parameter estimation. Additionally, MLE for mixtures of spherical Gaussians has been shown to be NP-hard [TD18], motivating the need to explore alternative methods to MLE.

There has been extensive research on analyzing the computational complexity of optimal transport algorithms [ALXG22, DGK18]. While our study does not focus on algorithmic efficiency, it presents one of the first results on parameter estimation within the optimal transport framework.

Our contributions are as follows: In Section 2, we develop a polynomial-time method for approximating the optimal  $\mu$  and  $\sigma$  using a Wasserstein minimization framework. In Section 3, we establish the NP-hardness of finding  $\mu$  through Maximum Likelihood Estimation (MLE) for general distributions. Section 4 raises several open questions, highlighting potential directions for future research.

## 2 Parameter Estimation in Wasserstein Minimization

### 2.1 Setup and Explicit Formulas for Parameter Estimation

We consider a distribution consisting of a finite union of hyperrectangles and a set of sample points. Our objective is to estimate the parameters  $\mu$  and  $\sigma$  from the discrete samples to minimize the Wasserstein distance induced by these parameters. This problem can be effectively framed as a semidiscrete transport problem. In other words, the selection of  $\mu, \sigma$  is regarded as finding values of these parameters that minimize the transport distance between the sample points, regarded as a sum of delta-functions, and the underlying distributions.

We will adopt the framework established in [PC19] for computational optimal transport in the semi-discrete setup. We will prove that there is a polynomial-time algorithm for estimating  $\mu$  and  $\sigma$  in the semidiscrete setup. Consider the semi-discrete transportation problem where  $c(\mathbf{x}, \mathbf{y}_j) \in \mathbb{R}$  represents the cost of transporting from continuous source  $\mathbf{x} \in \mathbb{R}^l$  to  $n$  discrete sinks  $\mathbf{y}_j \in \mathbb{R}^l$ , for  $1 \leq j \leq n$ , i.e.,  $c : \mathbb{R}^l \times \{\mathbf{y}_1, \dots, \mathbf{y}_n\} \rightarrow \mathbb{R}_+$ . The optimal transport cost can be represented as

follow:

$$\begin{aligned}
& \min_{\pi} \int_{\mathbb{R}^l} \sum_{j=1}^n c(\mathbf{x}, \mathbf{y}_j) d\pi(\mathbf{x}, \mathbf{y}_j) \\
& \text{subject to } \sum_{j=1}^n d\pi(\mathbf{x}, \mathbf{y}_j) = d\alpha(\mathbf{x}) \quad \forall \mathbf{x} \in \mathbb{R}^l, \\
& \int_{\mathbb{R}^l} d\pi(\mathbf{x}, \mathbf{y}_j) = b_j \quad \forall j = 1, \dots, n, \\
& \pi \geq 0.
\end{aligned} \tag{1}$$

Here,  $\pi : \mathbb{R}^l \times \{\mathbf{y}_1, \dots, \mathbf{y}_n\} \rightarrow \mathbb{R}$  is the semidiscrete optimal transport map that measures the flow from  $\mathbf{x}$  to  $\mathbf{y}_i$ , for  $i = 1, \dots, n$ . The given measure  $d\alpha(\mathbf{x})$  represents the capacity at  $\mathbf{x} \in \mathbb{R}^l$ , and  $b_j \geq 0$  represents the demand at sink  $j$ ,  $j = 1, \dots, n$ .

In the original problem we aim to address, we have  $b_j = \frac{1}{n}$  for all  $j$  where  $n$  is the number of sample points since the samples are presumed to be drawn independently at random. However we retain the above formulation for most of our analysis for some level of generality.

The problem is feasible if these capacities are all nonnegative and satisfy the compatibility condition

$$\int_{\mathbb{R}^l} d\alpha(\mathbf{x}) = \sum_{j=1}^n b_j = N. \tag{2}$$

Given these assumptions, the problem is bounded, ensuring the existence of an optimizer. Notably, this optimizer shares the same optimal value as its dual formulation, as discussed in Villani's work on optimal transport [Vil08]. In the dual form, the problem is expressed as:

$$\mathcal{L}_c(\alpha, \mathbf{b}) = \max_{\mathbf{g} \in \mathbb{R}^n} \left( \int_{\mathbb{R}^l} \mathbf{g}^{\bar{c}}(\mathbf{x}) d\alpha(\mathbf{x}) + \sum_{j=1}^n g_j b_j \right)$$

where  $\mathbf{g}^{\bar{c}}(\mathbf{x}) := \min_{1 \leq j \leq n} c(\mathbf{x}, \mathbf{y}_j) - g_j$ , where  $c(\mathbf{x}, \mathbf{y}_j) := \|\sigma \mathbf{x} - \mathbf{y}_j - \boldsymbol{\mu}\|^2$ . We can view this as the following infinite linear program:

$$\begin{aligned}
& \max_{\mathbf{g}, \mathbf{h}} \int_{\mathbb{R}^l} h(\mathbf{x}) d\alpha(\mathbf{x}) + \sum_{j=1}^n g_j b_j \\
& \text{subject to } h(\mathbf{x}) + g_j \leq c(\mathbf{x}, \mathbf{y}_j), \quad 1 \leq j \leq n, \quad \forall \mathbf{x} \in \mathbb{R}^l.
\end{aligned}$$

Here,  $\mathbf{g} \in \mathbb{R}^n$  and  $h$  is a function  $\mathbb{R}^l \rightarrow \mathbb{R}$ . The following theorem, established in [PC19], is included here for the sake of completeness.

**Theorem 2.1.** *Assume  $c(\mathbf{x}, \mathbf{y}_j)$  has the form  $\|\mathbf{x} - \mathbf{y}_j - \boldsymbol{\mu}\|^2$ . Then the primal optimal solution  $\pi$  is independent of  $\boldsymbol{\mu}$ .*

*Proof.* Let  $P(\boldsymbol{\mu})$  denote the instance of the program above for a particular choice of  $\boldsymbol{\mu}$  as in the theorem. Let  $DP(\boldsymbol{\mu})$  denote the corresponding dual instance. Let  $\pi^* : \mathbb{R}^l \times \{\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_n\} \rightarrow \mathbb{R}$  be the optimal solution to  $P(\mathbf{0})$  (i.e.,  $\boldsymbol{\mu}$  is taken to be  $\mathbf{0}$ ) and let  $\mathbf{g}^* \in \mathbb{R}^n, h^* : \mathbb{R}^l \rightarrow \mathbb{R}$  be the optimal solution for  $DP(\mathbf{0})$ . By complementary slackness on  $\pi^*$  and  $\mathbf{g}^*, h^*$ , we have

$$\pi^*(\mathbf{x}, \mathbf{y}_j)(\|\mathbf{x} - \mathbf{y}_j\|^2 - g_j^* - h^*(\mathbf{x})) = 0, \quad \forall \mathbf{x} \in \mathbb{R}^l, j \in \{1, 2, \dots, n\} \text{ almost surely.}$$

Now, fix an arbitrary  $\boldsymbol{\mu}$ . Take

$$\hat{g}_j = g_j^* + 2\boldsymbol{\mu}^\top \mathbf{y}_j + \|\boldsymbol{\mu}\|^2 \quad \text{and} \quad \hat{h}(\mathbf{x}) = h^*(\mathbf{x}) - 2\boldsymbol{\mu}^\top \mathbf{x},$$

for any  $\mathbf{x} \in \mathbb{R}^l$  and  $j \in \{1, 2, \dots, n\}$ . We have

$$\begin{aligned} \|\mathbf{x} - \mathbf{y}_j - \boldsymbol{\mu}\|^2 - \hat{g}_j - \hat{h}(\mathbf{x}) &= \|\mathbf{x} - \mathbf{y}_j\|^2 + \|\boldsymbol{\mu}\|^2 - 2\boldsymbol{\mu}^\top (\mathbf{x} - \mathbf{y}_j) - \hat{g}_j - \hat{h}(\mathbf{x}) \\ &= \|\mathbf{x} - \mathbf{y}_j\|^2 + (\|\boldsymbol{\mu}\|^2 + 2\boldsymbol{\mu}^\top \mathbf{y}_j - \hat{g}_j) + (-2\boldsymbol{\mu}^\top \mathbf{x} - \hat{h}(\mathbf{x})) \\ &= \|\mathbf{x} - \mathbf{y}_j\|^2 - g_j^* - h^*(\mathbf{x}). \end{aligned}$$

Since  $(\mathbf{g}^*, h^*)$  is feasible for  $DP(\mathbf{0})$ , the quantity is nonpositive and thus  $(\hat{\mathbf{g}}, \hat{h})$  is feasible for  $DP(\boldsymbol{\mu})$ . This therefore gives us

$$\pi^*(\mathbf{x}, \mathbf{y}_j)(\|\mathbf{x} - \mathbf{y}_j\|^2 - g_j^* - h^*(\mathbf{x})) = \pi^*(\mathbf{x}, \mathbf{y}_j)(\|\mathbf{x} - \mathbf{y}_j - \boldsymbol{\mu}\|^2 - \hat{g}_j - \hat{h}(\mathbf{x})),$$

which implies that by complementary slackness,  $\pi^*$  is an optimal solution to  $P(\boldsymbol{\mu})$  as well.  $\square$

**Remark 2.2.** *Because of the setup, the optimal transport map is not uniquely determined: the set for which it is not determined consists of a finite union of measure-zero disjoint polytopes corresponding to the boundaries of Laguerre cells (see Equation (8)) meeting hyperrectangles. However, complementary slackness holds at every point. Thus, the "almost surely" qualifier is unnecessary in our setting, and the dual program, introduced in Equation (3), has a unique solution. We will omit such phrases for the rest of our paper.*

**Theorem 2.3.** *In this setup, where we have  $c(\mathbf{x}, \mathbf{y}_j) = \|\sigma\mathbf{x} - \mathbf{y}_j\|^2$  for some  $\sigma > 0$ , the primal optimal solution  $\pi$  is independent of  $\sigma$ .*

*Proof.* Let  $P(\sigma)$  denote the instance of the program above for a particular choice of  $\sigma$  as in the theorem. Let  $DP(\sigma)$  denote the corresponding dual instance. Let  $\pi^* : \mathbb{R}^l \times \{\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_n\} \rightarrow \mathbb{R}$  be the optimal solution to  $P(1)$  and let  $\mathbf{g}^* \in \mathbb{R}^n, h^* : \mathbb{R}^l \rightarrow \mathbb{R}$  be the optimal solution for  $DP(1)$ . By complementary slackness on  $\pi^*$  and  $\mathbf{g}^*, h^*$ , we have

$$\pi^*(\mathbf{x}, \mathbf{y}_j)(\|\mathbf{x} - \mathbf{y}_j\|^2 - g_j^* - h^*(\mathbf{x})) = 0, \quad \forall \mathbf{x} \in \mathbb{R}^l, j \in \{1, 2, \dots, n\}.$$

Now, fix an arbitrary  $\sigma \in \mathbb{R}_{++}$ . Take

$$\hat{g}_j := (1 - \sigma)\|\mathbf{y}_j\|^2 + \sigma \cdot g_j^* \quad \text{and} \quad \hat{h}(\mathbf{x}) := (\sigma^2 - \sigma)\|\mathbf{x}\|^2 + \sigma \cdot h^*(\mathbf{x})$$

for any  $\mathbf{x} \in \mathbb{R}^l$  and  $j \in \{1, 2, \dots, n\}$ . We have

$$\begin{aligned} \|\sigma\mathbf{x} - \mathbf{y}_j\|^2 - \hat{g}_j - \hat{h}(\mathbf{x}) &= \sigma\|\mathbf{x} - \mathbf{y}_j\|^2 - (\hat{g}_j - (1 - \sigma)\|\mathbf{y}_j\|^2) - (\hat{h}(\mathbf{x}) - (\sigma^2 - \sigma)\|\mathbf{x}\|^2) \\ &= \sigma(\|\mathbf{x} - \mathbf{y}_j\|^2 - g_j^* - h^*(\mathbf{x})). \end{aligned}$$

Since  $(\mathbf{g}^*, h^*)$  is feasible for  $DP(1)$ , the quantity is nonpositive and thus  $(\hat{\mathbf{g}}, \hat{h})$  is feasible for  $DP(\sigma)$ . This therefore gives us

$$\sigma \cdot \pi^*(\mathbf{x}, \mathbf{y}_j)(\|\mathbf{x} - \mathbf{y}_j\|^2 - g_j^* - h^*(\mathbf{x})) = \pi^*(\mathbf{x}, \mathbf{y}_j)(\|\sigma\mathbf{x} - \mathbf{y}_j\|^2 - \hat{g}_j - \hat{h}(\mathbf{x}))$$

which implies that by complementary slackness,  $\pi^*$  is an optimal solution to  $P(\sigma)$  as well.  $\square$

Combining both of the theorem above give us the following corollary.

**Corollary 2.4.** *Suppose that there exists  $\mathbf{y}_1, \dots, \mathbf{y}_n \in \mathbb{R}^l$  and  $\boldsymbol{\mu} \in \mathbb{R}^l, \sigma \in \mathbb{R}_{++}$  such that for all  $\mathbf{x} \in \mathbb{R}^l, j \in \{1, \dots, n\}$ ,  $c(\mathbf{x}, \mathbf{y}_j) = \|\sigma \mathbf{x} - \mathbf{y}_j - \boldsymbol{\mu}\|^2$ . Then the primal optimal solution  $\pi$  is independent of  $\boldsymbol{\mu}$  and  $\sigma$ .*

We note that if  $\pi$  is the optimal transport map, then the optimal objective value of (1) for general  $\boldsymbol{\mu} \in \mathbb{R}^l, \sigma \in \mathbb{R}$  is

$$f(\boldsymbol{\mu}, \sigma) = \int_{\mathbb{R}^l} \sum_{j=1}^n \|\sigma \mathbf{x} - \mathbf{y}_j - \boldsymbol{\mu}\|^2 d\pi(\mathbf{x}, \mathbf{y}_j)$$

**Theorem 2.5.** *The optimal choices of  $\boldsymbol{\mu}^*$  and  $\sigma^*$  are given by the formulas:*

$$\sigma^* = \frac{N \left( \int_{\mathbb{R}^l} \sum_{j=1}^n \mathbf{x}^\top \mathbf{y}_j d\pi(\mathbf{x}, \mathbf{y}_j) \right) - \left( \sum_{j=1}^n b_j \mathbf{y}_j \right)^\top \left( \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right)}{N \left( \int_{\mathbb{R}^l} \|\mathbf{x}\|^2 d\alpha(\mathbf{x}) \right) - \left\| \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right\|^2} \quad (3)$$

$$\boldsymbol{\mu}^* = \frac{\sigma^* \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) - \sum_{j=1}^n b_j \mathbf{y}_j}{N}, \quad (4)$$

where  $N$  is given by equation (2).

*Proof.* We will find  $(\boldsymbol{\mu}^*, \sigma^*) \in \arg \min_{\boldsymbol{\mu}, \sigma} f(\boldsymbol{\mu}, \sigma)$ . To do this, note that  $f$  is a convex quadratic function of  $\boldsymbol{\mu}$  and  $\sigma$ . As  $(\boldsymbol{\mu}^*, \sigma^*)$  is a critical point of  $f$ , we have

$$\mathbf{0} = \frac{\partial f}{\partial \boldsymbol{\mu}}(\boldsymbol{\mu}, \sigma) \Big|_{\boldsymbol{\mu}^*, \sigma^*} = \int_{\mathbb{R}^l} \sum_{j=1}^n 2(\boldsymbol{\mu}^* + \mathbf{y}_j - \sigma^* \mathbf{x}) d\pi(\mathbf{x}, \mathbf{y}_j)$$

$$0 = \frac{\partial f}{\partial \sigma}(\boldsymbol{\mu}, \sigma) \Big|_{\boldsymbol{\mu}^*, \sigma^*} = \int_{\mathbb{R}^l} \sum_{j=1}^n 2\mathbf{x}^\top (\sigma^* \mathbf{x} - \mathbf{y}_j - \boldsymbol{\mu}^*) d\pi(\mathbf{x}, \mathbf{y}_j)$$

This yields the following two linear equations with respect to  $\boldsymbol{\mu}^*$  and  $\sigma^*$ :

$$\begin{aligned} \boldsymbol{\mu}^* \int_{\mathbb{R}^l} \sum_{j=1}^n 1 d\pi(\mathbf{x}, \mathbf{y}_j) - \sigma^* \int_{\mathbb{R}^l} \sum_{j=1}^n \mathbf{x} d\pi(\mathbf{x}, \mathbf{y}_j) + \int_{\mathbb{R}^l \times \{1, \dots, n\}} \mathbf{y}_j d\pi(\mathbf{x}, \mathbf{y}_j) &= \mathbf{0} \\ -(\boldsymbol{\mu}^*)^\top \int_{\mathbb{R}^l} \sum_{j=1}^n \mathbf{x} d\pi(\mathbf{x}, \mathbf{y}_j) + \sigma^* \int_{\mathbb{R}^l} \sum_{j=1}^n \|\mathbf{x}\|^2 d\pi(\mathbf{x}, \mathbf{y}_j) - \int_{\mathbb{R}^l} \sum_{j=1}^n \mathbf{x}^\top \mathbf{y}_j d\pi(\mathbf{x}, \mathbf{y}_j) &= 0 \end{aligned}$$

Solving these equations, we obtain

$$\begin{aligned} \sigma^* &= \frac{N \left( \int_{\mathbb{R}^l} \sum_{j=1}^n \mathbf{x}^\top \mathbf{y}_j d\pi(\mathbf{x}, \mathbf{y}_j) \right) - \left( \sum_{j=1}^n b_j \mathbf{y}_j \right)^\top \left( \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right)}{N \left( \int_{\mathbb{R}^l} \|\mathbf{x}\|^2 d\alpha(\mathbf{x}) \right) - \left\| \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right\|^2} \\ \boldsymbol{\mu}^* &= \frac{\sigma^* \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) - \sum_{j=1}^n b_j \mathbf{y}_j}{N}, \end{aligned}$$

as desired. □

The theorem provides explicit optimal formulas for  $\boldsymbol{\mu}^*$  and  $\sigma^*$ . Most of the terms appearing in the above formulas can be computed directly. However, the integral

$$\int_{\mathbb{R}^l} \sum_{j=1}^n \mathbf{x}^\top \mathbf{y}_j d\pi(\mathbf{x}, \mathbf{y}_j)$$

requires knowledge of the optimal primal solution, making it apparently computationally infeasible to determine in polynomial time. Consequently at first glance, finding the exact values of  $\boldsymbol{\mu}^*$  and  $\sigma^*$  appears to be intractable. We resolve this issue in forthcoming sections.

## 2.2 Polynomial-Time Algorithm for Parameter Estimation

The main theorem of this section, Theorem 2.7, asserts that  $\boldsymbol{\mu}^*$  and  $\sigma^*$  can be estimated in polynomial time under the assumption that the source distribution  $d\alpha(\mathbf{x})$  is piecewise constant over a finite number of hyperrectangles. For our analysis, as mentioned in Section 1, we will henceforth assume that the source distribution  $d\alpha(\mathbf{x})$  comes from  $\mathcal{C}$ , where  $\mathcal{C}$  denote the class of probability distributions that are piecewise constant over a finite number of hyperrectangles, i.e., there exists  $k \in \mathbb{N}$ ,  $k$  disjoint hyperrectangles  $\mathcal{H}_1, \mathcal{H}_2, \dots, \mathcal{H}_k \subseteq \mathbb{R}^l$  and  $k$  positive reals  $\gamma_1, \dots, \gamma_k$  for which

$$d\alpha(\mathbf{x}) = \begin{cases} \gamma_i d\mathbf{x}, & \text{if } \mathbf{x} \in \mathcal{H}_i \text{ for some } 1 \leq i \leq k, \\ 0, & \text{otherwise.} \end{cases}$$

As  $\alpha$  is a probability distribution, it follows that  $\sum_{i=1}^k \gamma_i \cdot \text{vol}(\mathcal{H}_i) = N = 1$ . From here on, we will fix  $N = 1$ . Let  $\mathcal{F}$  denote the class of probability distributions characterized by a nonnegative Riemann integrable function  $\varphi$ , where  $\varphi : \mathbb{R}^l \rightarrow \mathbb{R}$  satisfies  $\int_{\mathbb{R}^l} \varphi(\mathbf{x}) d\mathbf{x} = 1$ . In fact, the general class of distributions  $\mathcal{F}$  can be approximated arbitrarily closely by the class  $\mathcal{C}$  by definition of Riemann integrability [AE13].

**Claim 2.6.** *For any probability distribution  $f \in \mathcal{F}$  and any  $\varepsilon > 0$ , there exists  $g \in \mathcal{C}$  such that*

$$\int_{\mathbb{R}^l} |f(\mathbf{x}) - g(\mathbf{x})| d\mathbf{x} < \varepsilon.$$

This motivates our focus on the class of distributions  $\mathcal{C}$  for our algorithm design. While the class  $\mathcal{C}$  provides sufficient generality for our purposes, extending the algorithm to the broader function class  $\mathcal{F}$  is not immediate due to Claim 2.6's implicit exponential dependence on  $l$ .

We now highlight several key parameters that play a crucial role in our analysis, which dictates the runtime of our parameter estimation algorithm for Wasserstein minimization. For convenience, we define a **reference set**  $\mathcal{X} \subseteq \mathbb{R}^l$ , which consists of all corners of the  $k$  hyperrectangles, along with all sample points. Specifically, if each of the  $k$  hyperrectangles is described by  $\mathcal{H}_i = [a_{i,1}, b_{i,1}] \times [a_{i,2}, b_{i,2}] \times \dots \times [a_{i,l}, b_{i,l}]$ , we define

$$\begin{aligned} \mathcal{X}_1 &= \{\mathbf{y}_j\}_{j=1}^n \\ \mathcal{X}_2 &= \bigcup_{i=1}^k \left\{ (x_{i,1}, x_{i,2}, \dots, x_{i,l}) \mid x_{i,h} \in \{a_{i,h}, b_{i,h}\} \text{ for each } h = 1, 2, \dots, l \right\} \\ \mathcal{X} &= \mathcal{X}_1 \cup \mathcal{X}_2 \end{aligned}$$

and thus  $\mathcal{X}$  is a set of size at most  $k \cdot 2^l + n$ .

**Theorem 2.7.** Let  $n$  be the number of sample points,  $l$  be the dimensionality of the space,  $k$  be the number of hyperrectangles characterizing the source distribution,  $D = \max_{\mathbf{x} \in \mathcal{X}} \|\mathbf{x}\|$  and  $s = \min\{\min_{\substack{\mathbf{x}, \mathbf{y} \in \mathcal{X}_1 \\ \mathbf{x} \neq \mathbf{y}}} \|\mathbf{x} - \mathbf{y}\|, \min_{\substack{1 \leq i \leq k \\ 1 \leq j \leq l}} |b_{i,j} - a_{i,j}|\}$ . There exists a randomized polynomial-time algorithm with a runtime of

$$\text{poly}\left(n, l, k, D, \frac{1}{s}, \frac{1}{\varepsilon}, \log \frac{1}{\eta}\right)$$

that estimates  $\boldsymbol{\mu}^*$  within  $\varepsilon D$ -accuracy and  $\sigma^*$  within  $\varepsilon$ -accuracy with probability at least  $1 - \eta$ .

**Remark 2.8.** We first remark that as  $D = \max_{\mathbf{x} \in \mathcal{X}} \|\mathbf{x}\|$ , we have

$$\max_{\mathbf{x}, \mathbf{y} \in \mathcal{X}} \|\mathbf{x} - \mathbf{y}\| \leq 2D.$$

*Proof.* From equations (3) and (4), the optimal values of  $\boldsymbol{\mu}^*$  and  $\sigma^*$  can be expressed as:

$$\begin{aligned} \sigma^* &= \frac{N \left( \int_{\mathbb{R}^l} \sum_{j=1}^n \mathbf{x}^\top \mathbf{y}_j d\pi(\mathbf{x}, \mathbf{y}_j) \right) - \left( \sum_{j=1}^n b_j \mathbf{y}_j \right)^\top \left( \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right)}{N \left( \int_{\mathbb{R}^l} \|\mathbf{x}\|^2 d\alpha(\mathbf{x}) \right) - \left\| \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right\|^2}, \\ \boldsymbol{\mu}^* &= \frac{\sigma^* \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) - \sum_{j=1}^n b_j \mathbf{y}_j}{N}. \end{aligned}$$

The terms  $\int_{\mathbb{R}^l} \|\mathbf{x}\|^2 d\alpha(\mathbf{x})$ ,  $\int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x})$ , and  $\sum_{j=1}^n b_j \mathbf{y}_j$  can all be computed explicitly. To compute  $\int_{\mathbb{R}^l} \|\mathbf{x}\|^2 d\alpha(\mathbf{x})$ , observe that this integral can be expressed as  $\sum_{i=1}^k \gamma_i \int_{\mathcal{H}_i} \|\mathbf{x}\|^2 d\mathbf{x}$ . By denoting  $\mathcal{H}_i = [a_{i,1}, b_{i,1}] \times [a_{i,2}, b_{i,2}] \times \cdots \times [a_{i,l}, b_{i,l}]$  for each  $i$ , we have

$$\begin{aligned} \int_{\mathcal{H}_i} \|\mathbf{x}\|^2 d\mathbf{x} &= \int_{a_{i,1}}^{b_{i,1}} \int_{a_{i,2}}^{b_{i,2}} \cdots \int_{a_{i,l}}^{b_{i,l}} (x_1^2 + x_2^2 + \cdots + x_l^2) dx_1 dx_2 \cdots dx_l \\ &= \frac{1}{3} \sum_{j=1}^l (b_{i,j}^3 - a_{i,j}^3) \prod_{h \neq j} (b_{i,h} - a_{i,h}). \end{aligned}$$

Thus,  $\int_{\mathbb{R}^l} \|\mathbf{x}\|^2 d\alpha(\mathbf{x})$  can be computed explicitly as

$$\int_{\mathbb{R}^l} \|\mathbf{x}\|^2 d\alpha(\mathbf{x}) = \frac{1}{3} \sum_{i=1}^k \gamma_i \sum_{j=1}^l (b_{i,j}^3 - a_{i,j}^3) \prod_{h \neq j} (b_{i,h} - a_{i,h}).$$

The remaining terms,  $\int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x})$  and  $\sum_{j=1}^n b_j \mathbf{y}_j$ , can be evaluated in a similar manner.

To compute  $\int_{\mathbb{R}^l} \sum_{j=1}^n \mathbf{x}^\top \mathbf{y}_j d\pi(\mathbf{x}, \mathbf{y}_j)$ , consider the case where  $\boldsymbol{\mu} = \mathbf{0}$  and  $\sigma = 1$ , with  $\pi$  as the primal optimal solution. The corresponding primal optimal cost is:

$$p^* = \int_{\mathbb{R}^l} \sum_{j=1}^n \|\mathbf{x} - \mathbf{y}_j\|^2 d\pi(\mathbf{x}, \mathbf{y}_j).$$

Expanding and substituting the constraints in (1), we find:

$$p^* = \int_{\mathbb{R}^l} \|\mathbf{x}\|^2 d\alpha(\mathbf{x}) + \sum_{j=1}^n b_j \|\mathbf{y}_j\|^2 - 2 \int_{\mathbb{R}^l} \sum_{j=1}^n \mathbf{x}^\top \mathbf{y}_j d\pi(\mathbf{x}, \mathbf{y}_j).$$

Thus,  $\int_{\mathbb{R}^l} \sum_{j=1}^n \mathbf{x}^\top \mathbf{y}_j d\pi(\mathbf{x}, \mathbf{y}_j)$  can be computed directly from  $p^*$ , which does not need  $\pi$ .

By the Strong Duality Theorem, the optimal primal cost  $p^*$  is equal to the optimal value of the dual program:

$$\begin{aligned} \max_{\mathbf{g}, h} \int_{\mathbb{R}^l} h(\mathbf{x}) d\alpha(\mathbf{x}) + \sum_{j=1}^n g_j b_j \\ \text{subject to } g_j + h(\mathbf{x}) \leq c(\mathbf{x}, \mathbf{y}_j), \quad \forall \mathbf{x} \in \mathbb{R}^l, \quad \forall j = 1, \dots, n. \end{aligned} \quad (5)$$

It suffices to show that we can estimate the optimal value  $p^*$  to the dual program sufficiently close enough efficiently for  $\boldsymbol{\mu} = \mathbf{0}$  and  $\sigma = 1$  (the cost function of the dual program is thus  $c(\mathbf{x}, \mathbf{y}_j) = \|\mathbf{x} - \mathbf{y}_j\|^2$ ) in polynomial time. To achieve this, we need to maximize the energy function  $\mathcal{E}(\mathbf{g})$  in polynomial time. Following the definition in [PC19], we may define the function the energy function  $\mathcal{E}(h, \mathbf{g})$  as

$$\mathcal{E}(h, \mathbf{g}) := \int_{\mathbb{R}^l} h(\mathbf{x}) d\alpha(\mathbf{x}) + \sum_j g_j \beta_j - \iota_{\Gamma}(h, \mathbf{g}), \quad (6)$$

where  $\Gamma$  is the feasible region of (5) and the indicator function  $\iota_{\Gamma}$  is defined as:

$$\iota_{\Gamma}(h, \mathbf{g}) = \begin{cases} 0 & \text{if } g_i + h(\mathbf{x}) \leq c(\mathbf{x}, \mathbf{y}_j), \quad \forall \mathbf{x} \in \mathbb{R}^l, \quad \forall j = 1, \dots, n, \\ +\infty & \text{otherwise.} \end{cases}$$

It follows that  $\mathcal{E}(h, \mathbf{g})$  is a concave function with respect to both  $h$  and  $\mathbf{g}$ . We further define  $\mathcal{E}(\mathbf{g}) = \max_h \mathcal{E}(h, \mathbf{g})$ . By Proposition 8.35 in [BC11], it follows that  $\mathcal{E}(\mathbf{g})$  is also concave.

To explicitly derive  $\mathcal{E}(\mathbf{g})$ , observe that  $h$  is weighted nonnegatively in the definition of  $\mathcal{E}(h, \mathbf{g})$ . Therefore,  $\max_h \mathcal{E}(h, \mathbf{g})$  is obtained by setting  $h$  pointwise to its maximum value while satisfying the constraints. Specifically, for each  $\mathbf{x}$ ,  $h(\mathbf{x})$  should be chosen such that  $h(\mathbf{x}) + g_j \leq c(\mathbf{x}, \mathbf{y}_j)$  for all  $j$ , with at least one  $j$  where equality holds:  $h(\mathbf{x}) + g_j = c(\mathbf{x}, \mathbf{y}_j)$ . Consequently,  $h(\mathbf{x})$  should be set to  $\min_j (c(\mathbf{x}, \mathbf{y}_j) - g_j)$  for all  $\mathbf{x}$ .

This allows us to write the minimized energy  $\mathcal{E}(\mathbf{g})$  for any  $\mathbf{g} \in \mathbb{R}^n$  explicitly as

$$\mathcal{E}(\mathbf{g}) = \sum_{j=1}^n \int_{\mathbb{L}_j(\mathbf{g})} (c(\mathbf{x}, \mathbf{y}_j) - g_j) d\alpha(\mathbf{x}) + \langle \mathbf{g}, \mathbf{b} \rangle, \quad (7)$$

where  $c(\mathbf{x}, \mathbf{y}_j) \in \mathbb{R}$  is the cost function, and in this paper, we specifically consider  $c(\mathbf{x}, \mathbf{y}_j) = \|\mathbf{x} - \mathbf{y}_j\|^2$ . Here,  $\mathbb{L}_j(\mathbf{g})$  denotes the *Laguerre cell* associated with the dual weights  $\mathbf{g}$ , i.e.,

$$\mathbb{L}_j(\mathbf{g}) = \{\mathbf{x} \in \mathbb{R}^l : \forall j' \neq j, \|\mathbf{x} - \mathbf{y}_j\|^2 - g_j \leq \|\mathbf{x} - \mathbf{y}_{j'}\|^2 - g_{j'}\} \quad (8)$$

which induces a decomposition of  $\mathbb{R}^l$  as  $\mathbb{R}^l = \bigcup_{1 \leq j \leq n} \mathbb{L}_j(\mathbf{g})$ , such that  $\text{int}(\mathbb{L}_j)$  are pairwise disjoint for  $1 \leq j \leq n$ . In the case  $\mathbf{g} = \mathbf{0}$ , Laguerre cells are commonly called Voronoi cells.

To maximize the energy  $\mathcal{E}(\mathbf{g})$ , we can apply inexact gradient ascent as the energy function  $\mathcal{E}$  is concave as established. The function  $\mathcal{E}(\mathbf{g})$  is differentiable and the gradient is given by [Pey21] as:

$$\nabla \mathcal{E}(\mathbf{g})_j = - \int_{\mathbb{L}_j(\mathbf{g})} d\alpha(\mathbf{x}) + b_j, \quad \forall j \in [n].$$

Under our source distribution's assumption, we can thus rewrite  $\nabla \mathcal{E}(\mathbf{g})_j$  as

$$\nabla \mathcal{E}(\mathbf{g})_j = \sum_{\ell=1}^k -\gamma_{\ell} \cdot \text{vol}(\mathbb{L}_j(\mathbf{g}) \cap \mathcal{H}_{\ell}) + b_j.$$

Note that for every  $1 \leq \ell \leq k$  and  $1 \leq j \leq n$ ,  $\mathbb{L}_j(\mathbf{g}) \cap \mathcal{H}_\ell$  is a convex body for which we can provide a separation oracle efficiently. By using Kannan, Lovasz, and Simonovits' Theorem which is stated in Theorem 2.9, given  $\varepsilon, \eta > 0$ , we can estimate  $\text{vol}(\mathbb{L}_j(\mathbf{g}) \cap \mathcal{H}_\ell)$  within  $\varepsilon$  accuracy with probability at least  $1 - \eta$  in polynomial time.

**Theorem 2.9** (Kannan, Lovasz, Simonovits [KLS97]). *Given a separation oracle of an  $n$ -dimensional convex body  $K$ , and  $\varepsilon, \eta > 0$ , there is an algorithm that uses  $O\left[\text{poly}\left(n, \frac{1}{\varepsilon}, \log \frac{1}{\eta}\right)\right]$  oracle calls which returns a real number  $\zeta$  for which*

$$\left| \frac{\text{vol}(K)}{\zeta} - 1 \right| < \varepsilon$$

with probability at least  $1 - \eta$ .

We now present the separation oracles for a fixed Laguerre cell, which, when combined with the theorem above, provide a method to compute  $\nabla \mathcal{E}(\mathbf{g})$  to within  $\varepsilon$ -accuracy in polynomial time. The separation oracle for a hyperrectangle is straightforward, as it can be determined by  $O(l)$  min/max operations. For Laguerre cells, the separation oracle can be constructed as follows: Given  $\mathbf{y}_1, \dots, \mathbf{y}_n$  and  $g_1, \dots, g_n$ , where  $\mathbf{y}_i \in \mathbb{R}^l$  and  $g_i \in \mathbb{R}$  for all  $1 \leq i \leq n$ , recall the definition of Laguerre cells associated with  $\mathbf{g}$ , as in (8). We will construct a separation oracle for a specific Laguerre cell  $\mathbb{L}_i(\mathbf{g})$ . Check whether  $\|\mathbf{x} - \mathbf{y}_i\|^2 - g_i \leq \|\mathbf{x} - \mathbf{y}_j\|^2 - g_j$  for  $1 \leq j \leq n$  as follow:

- If  $\|\mathbf{x} - \mathbf{y}_i\|^2 - g_i \leq \|\mathbf{x} - \mathbf{y}_j\|^2 - g_j$  for all  $1 \leq j \leq n$ , this means that  $\mathbf{x} \in \mathbb{L}_i(\mathbf{g})$  and the oracle will confirm that  $\mathbf{x}$  is inside the Laguerre cell  $\mathbb{L}_i(\mathbf{g})$ .
- Otherwise, pick the smallest  $1 \leq j \leq n$  where the inequality is violated, i.e. we have  $\|\mathbf{x} - \mathbf{y}_j\|^2 - g_j < \|\mathbf{x} - \mathbf{y}_i\|^2 - g_i$ , which is equivalent to  $2(\mathbf{y}_j - \mathbf{y}_i)^\top \mathbf{x} > g_i - g_j + \|\mathbf{y}_j\|^2 - \|\mathbf{y}_i\|^2$  and thus by picking the hyperplane  $\boldsymbol{\alpha}^\top \mathbf{x} = \beta$  where  $\boldsymbol{\alpha} = 2(\mathbf{y}_j - \mathbf{y}_i)$  and  $\beta = g_i - g_j + \|\mathbf{y}_j\|^2 - \|\mathbf{y}_i\|^2$ , we get a hyperplane that separates  $\mathbf{x}$  from the Laguerre cell  $\mathbb{L}_i(\mathbf{g})$ , as desired.

This establishes a separation oracle for a hyperrectangle that operates in  $O(l)$  time and a separation oracle for a Laguerre cell that operates in  $O(ln)$  time.

To establish an accurate complexity bound for applying inexact gradient descent to minimize the convex function  $-\mathcal{E}$ , we will first prove that  $\mathcal{E}$  is  $L$ -smooth, where  $L = \text{poly}\left(n, l, k, \frac{1}{s}\right)$  where  $n, l, k, s$  are defined in Theorem 2.7. Our proof begins by noting an important inequality regarding the ratio of the volume of a hyperrectangle and its projection to some subspace of dimension  $l - 1$ .

**Lemma 2.10.** *Let  $\mathcal{V} \in \mathbb{R}^l$  be a hyperrectangle with minimum width  $\xi$ , and let  $\mathcal{Z}$  be the projection of  $\mathcal{H}$  into an arbitrary subspace of dimension  $l - 1$ . Then,*

$$\text{vol}(\mathcal{Z}) \leq \frac{2l}{\xi} \cdot \text{vol}(\mathcal{V}).$$

*Proof.* Let  $\mathcal{W}$  be the facet of  $\mathcal{V}$  with the largest surface area. We know that  $\text{vol}(\mathcal{W}) \cdot \xi = \text{vol}(\mathcal{V})$ , i.e. we have  $\text{vol}(\mathcal{W}) = \frac{1}{\xi} \cdot \text{vol}(\mathcal{V})$ . We note that any orthogonal projection of the  $(l - 1)$ -facet  $\mathcal{W}$  onto a hyperplane can only decrease its volume because the projection of a  $(l - 1)$ -facet is a hyperparallelogram, and the volume of an  $(l - 1)$ -parallelogram is bounded by the product of the lengths of its sides by Hadamard's inequality. However, the side lengths of  $\mathcal{W}$  can only shrink under projection. This, thus shows us that  $\text{vol}(\text{proj}_{\mathcal{P}}(\mathcal{W})) \leq \frac{1}{\xi} \text{vol}(\mathcal{V})$  for any hyperplane  $\mathcal{P}$ .

Finally, we observe that  $\text{proj}_{\mathcal{P}}(\mathcal{V}) \subseteq \bigcup_i \text{proj}_{\mathcal{P}}(\mathcal{W}_i)$  where this union of  $\mathcal{W}_i$  ranges over all possible  $2l$  facets. To see this, let  $\mathbf{x} \in \text{int}(\mathcal{V})$  and let  $\mathbf{a}$  be the normal to the hyperplane  $\mathcal{P}$ . Then the segment from  $\text{proj}_{\mathcal{P}}(\mathbf{x})$  to  $\mathbf{x}$  is parallel to  $\mathbf{a}$  by definition of projection. However, extending this

segment to a line must pass through the boundary of  $\mathcal{V}$  twice, so there are two points on  $\partial\mathcal{V}$  that have the same projection as  $\mathbf{x}$ .

This thus shows that  $\text{vol}(\text{proj}_{\mathcal{P}}(\mathcal{V})) \leq \frac{2l}{\xi} \cdot \text{vol}(\mathcal{V})$  for any hyperplane  $\mathcal{P}$ , i.e. we must have  $\text{vol}(\mathcal{Z}) \leq \frac{2l}{\xi} \cdot \text{vol}(\mathcal{V})$ .  $\square$

By definition of  $s$  in Theorem 2.7, we have that the claim above holds even by replacing  $\xi$  with  $s$ , as we know that  $\xi \geq s$ . Before proving  $\mathcal{E}$  is  $L$ -smooth, we will prove a crucial claim regarding the square of the difference in volumes of Laguerre cells generated by two functions within a finite hyperrectangle. This claim will be the core of the proof of  $L$ -smoothness.

**Lemma 2.11.** *Given any finite hyperrectangle  $\mathcal{H}$ , and any  $\mathbf{g}, \mathbf{h} \in \mathbb{R}^n$ , we have*

$$\sum_{j=1}^n (\text{vol}(\mathbb{L}_j(\mathbf{g}) \cap \mathcal{H}) - \text{vol}(\mathbb{L}_j(\mathbf{h}) \cap \mathcal{H}))^2 \leq \frac{4n^2 l^2}{s^4} \text{vol}(\mathcal{H})^2 \sum_{j=1}^n |g_j - h_j|^2. \quad (9)$$

*Proof.* The key idea of this proof is to analyze the sum coordinate-wise. Consider  $\mathbf{f}_0, \mathbf{f}_1, \dots, \mathbf{f}_n \in \mathbb{R}^n$  where  $\mathbf{f}_0 = \mathbf{g}$ ,  $\mathbf{f}_n = \mathbf{h}$ , and for any  $1 \leq j \leq n-1$ , we have

$$(\mathbf{f}_i)_j = \begin{cases} h_j & \text{if } 1 \leq j \leq i \\ g_j & \text{otherwise} \end{cases}.$$

We first bound the LHS of (9) when  $\mathbf{g} := \mathbf{f}_{\ell-1}$  and  $\mathbf{h} := \mathbf{f}_\ell$  for any  $1 \leq \ell \leq n$ . Fix any  $1 \leq \ell \leq n$ . By definition of  $(\mathbf{f}_i)_{0 \leq i \leq n}$ , this reduces to proving

$$\sum_{j=1}^n (\text{vol}(\mathbb{L}_j(\mathbf{f}_{\ell-1}) \cap \mathcal{H}) - \text{vol}(\mathbb{L}_j(\mathbf{f}_\ell) \cap \mathcal{H}))^2 \leq c_\ell (g_\ell - h_\ell)^2 \text{vol}(\mathcal{H})^2$$

for some  $c_\ell \in \text{poly}(n, l, \frac{1}{s})$ . We note that by definition, we have

$$\begin{aligned} \mathbb{L}_j(\mathbf{f}_{\ell-1}) \cap \mathcal{H} &= \{\mathbf{x} \in \mathcal{H} : \|\mathbf{x} - \mathbf{y}_j\|^2 - (\mathbf{f}_{\ell-1})_j \leq \|\mathbf{x} - \mathbf{y}_i\|^2 - (\mathbf{f}_{\ell-1})_i \ \forall i\}, \\ \mathbb{L}_j(\mathbf{f}_\ell) \cap \mathcal{H} &= \{\mathbf{x} \in \mathcal{H} : \|\mathbf{x} - \mathbf{y}_j\|^2 - (\mathbf{f}_\ell)_j \leq \|\mathbf{x} - \mathbf{y}_i\|^2 - (\mathbf{f}_\ell)_i \ \forall i\}. \end{aligned}$$

By construction,  $(\mathbf{f}_\ell)_i = (\mathbf{f}_{\ell-1})_i$  for all  $i \neq \ell$ . Without loss of generality we may assume  $(\mathbf{f}_{\ell-1})_\ell = g_\ell \geq h_\ell = (\mathbf{f}_\ell)_\ell$ . We claim that

$$\mathbb{L}_\ell(\mathbf{f}_\ell) \cap \mathcal{H} \subseteq \mathbb{L}_\ell(\mathbf{f}_{\ell-1}) \cap \mathcal{H} \quad \text{and} \quad \mathbb{L}_i(\mathbf{f}_\ell) \cap \mathcal{H} \supseteq \mathbb{L}_i(\mathbf{f}_{\ell-1}) \cap \mathcal{H} \ \forall i \neq \ell$$

This is because for any  $\mathbf{x} \in \mathbb{L}_\ell(\mathbf{f}_\ell) \cap \mathcal{H}$ , we have

$$\|\mathbf{x} - \mathbf{y}_\ell\|^2 - (\mathbf{f}_{\ell-1})_\ell \leq \|\mathbf{x} - \mathbf{y}_\ell\|^2 - (\mathbf{f}_\ell)_\ell \leq \|\mathbf{x} - \mathbf{y}_i\|^2 - (\mathbf{f}_\ell)_i = \|\mathbf{x} - \mathbf{y}_i\|^2 - (\mathbf{f}_{\ell-1})_i$$

for all  $i \neq \ell$ , and thus  $\mathbf{x} \in \mathbb{L}_\ell(\mathbf{f}_{\ell-1}) \cap \mathcal{H}$ . The other inclusion follows similarly. Having the above inclusion in mind, we can simplify the volume difference as

$$\begin{aligned} (\text{vol}(\mathbb{L}_\ell(\mathbf{f}_{\ell-1}) \cap \mathcal{H}) - \text{vol}(\mathbb{L}_\ell(\mathbf{f}_\ell) \cap \mathcal{H}))^2 &= \text{vol}((\mathbb{L}_\ell(\mathbf{f}_{\ell-1}) \setminus \mathbb{L}_\ell(\mathbf{f}_\ell)) \cap \mathcal{H})^2, \\ (\text{vol}(\mathbb{L}_j(\mathbf{f}_{\ell-1}) \cap \mathcal{H}) - \text{vol}(\mathbb{L}_j(\mathbf{f}_\ell) \cap \mathcal{H}))^2 &= \text{vol}((\mathbb{L}_j(\mathbf{f}_\ell) \setminus \mathbb{L}_j(\mathbf{f}_{\ell-1})) \cap \mathcal{H})^2 \quad \forall j \neq \ell. \end{aligned}$$

Now, we note that  $\mathbf{x} \in \mathbb{L}_\ell(\mathbf{f}_{\ell-1}) \setminus \mathbb{L}_\ell(\mathbf{f}_\ell)$  implies that there exists  $p$  for which

$$\|\mathbf{x} - \mathbf{y}_p\|^2 - (\mathbf{f}_\ell)_p + h_\ell < \|\mathbf{x} - \mathbf{y}_\ell\|^2 \leq \|\mathbf{x} - \mathbf{y}_p\|^2 - (\mathbf{f}_\ell)_p + g_\ell$$

and we thus note that any such  $\mathbf{x}$  must lie in

$$\|\mathbf{y}_p\|^2 - \|\mathbf{y}_\ell\|^2 - (\mathbf{f}_\ell)_p + h_\ell < 2(\mathbf{y}_p - \mathbf{y}_\ell)^\top \mathbf{x} \leq \|\mathbf{y}_p\|^2 - \|\mathbf{y}_\ell\|^2 - (\mathbf{f}_\ell)_p + g_\ell,$$

i.e. there exists  $b_1, b_2 \in \mathbb{R}, \mathbf{a} \in \mathbb{R}^l$  for which  $b_1 < \mathbf{a}^\top \mathbf{x} \leq b_2$ , where  $b_2 - b_1 = g_\ell - h_\ell$  and  $\mathbf{a} = 2(\mathbf{y}_p - \mathbf{y}_\ell)$ . This means that  $\text{vol}((\mathbb{L}_\ell(\mathbf{f}_{\ell-1}) \setminus \mathbb{L}_\ell(\mathbf{f}_\ell)) \cap \mathcal{H})^2$  will be bounded above by

$$\text{vol}(\{\mathbf{x} \in \mathcal{H} : b_1 \leq \mathbf{a}^\top \mathbf{x} \leq b_2\})^2$$

Let  $\text{span}(\{\mathbf{a}\})^\perp$  be the orthogonal complement of subspace  $\text{span}(\{\mathbf{a}\}) \subseteq \mathcal{H}$  and define  $\mathcal{G} = \text{Proj}_{\text{span}(\{\mathbf{a}\})^\perp}(\mathcal{H})$ . We note that

$$\{\mathbf{x} \in \mathcal{H} : b_1 \leq \mathbf{a}^\top \mathbf{x} \leq b_2\} \subseteq \left\{ \mathbf{y} + \gamma \cdot \frac{\mathbf{a}}{\|\mathbf{a}\|} : \mathbf{y} \in \mathcal{G}, \gamma \in [b_1, b_2] \right\}$$

and thus we obtain

$$\text{vol}(\{\mathbf{x} \in \mathcal{H} : b_1 \leq \mathbf{a}^\top \mathbf{x} \leq b_2\})^2 \leq \frac{\text{vol}(\mathcal{G})^2}{\|\mathbf{a}\|^2} \cdot (b_2 - b_1)^2.$$

Here, we note that as  $\mathcal{G}$  is a projection of hyperrectangle  $\mathcal{H} \in \mathbb{R}^l$  to some subspace of dimension  $l - 1$ , we obtain from Lemma 2.10 that

$$\text{vol}(\mathcal{G})^2 \leq \frac{4l^2}{\xi^2} \text{vol}(\mathcal{H})^2 \leq \frac{4l^2}{s^2} \text{vol}(\mathcal{H})^2,$$

and thus we obtain

$$\text{vol}(\{\mathbf{x} \in \mathcal{H} : b_1 \leq \mathbf{a}^\top \mathbf{x} \leq b_2\})^2 \leq \frac{4l^2}{s^4} \cdot (g_\ell - h_\ell)^2 \cdot \text{vol}(\mathcal{H})^2$$

where by definition,  $s \leq \min_{1 \leq i < j \leq n} \|\mathbf{y}_i - \mathbf{y}_j\| \leq \frac{1}{2}\|\mathbf{a}\|$ . Similarly, when  $j \neq \ell$ , note that  $\mathbf{x} \in \mathbb{L}_j(\mathbf{f}_\ell) \setminus \mathbb{L}_j(\mathbf{f}_{\ell-1})$  implies that there exists  $p$  for which

$$\|\mathbf{x} - \mathbf{y}_p\|^2 - (\mathbf{f}_{\ell-1})_p < \|\mathbf{x} - \mathbf{y}_j\|^2 - (\mathbf{f}_{\ell-1})_j$$

while  $\|\mathbf{x} - \mathbf{y}_j\|^2 - (\mathbf{f}_\ell)_j \leq \|\mathbf{x} - \mathbf{y}_p\|^2 - (\mathbf{f}_\ell)_p$ . This forces  $p = \ell$ , and thus we have

$$\|\mathbf{x} - \mathbf{y}_\ell\|^2 - g_\ell < \|\mathbf{x} - \mathbf{y}_j\|^2 - (\mathbf{f}_{\ell-1})_j = \|\mathbf{x} - \mathbf{y}_j\|^2 - (\mathbf{f}_\ell)_j \leq \|\mathbf{x} - \mathbf{y}_\ell\|^2 - h_\ell$$

and we thus note that any such  $\mathbf{x}$  must lie in

$$\|\mathbf{y}_\ell\|^2 - \|\mathbf{y}_j\|^2 + (\mathbf{f}_\ell)_j - g_\ell < 2(\mathbf{y}_\ell - \mathbf{y}_j)^\top \mathbf{x} \leq \|\mathbf{y}_\ell\|^2 - \|\mathbf{y}_j\|^2 + (\mathbf{f}_\ell)_j - h_\ell,$$

i.e. there exists  $b_1, b_2 \in \mathbb{R}, \mathbf{a} \in \mathbb{R}^l$  for which  $b_1 < \mathbf{a}^\top \mathbf{x} \leq b_2$ , where  $b_2 - b_1 = g_\ell - h_\ell$  and  $\mathbf{a} = 2(\mathbf{y}_\ell - \mathbf{y}_j)$ . This means that  $\text{vol}((\mathbb{L}_j(\mathbf{f}_\ell) \setminus \mathbb{L}_j(\mathbf{f}_{\ell-1})) \cap \mathcal{H})^2$  will be bounded above by

$$\text{vol}(\{\mathbf{x} \in \mathcal{H} : b_1 \leq \mathbf{a}^\top \mathbf{x} \leq b_2\})^2$$

and by a similar argument, we can argue that this volume is bounded above by  $\frac{4l^2}{s^4} \cdot (g_\ell - h_\ell)^2 \cdot \text{vol}(\mathcal{H})^2$ . Summing the bounds for  $1 \leq j \leq n$ , we thus obtain

$$\sum_{j=1}^n (\text{vol}(\mathbb{L}_j(\mathbf{f}_{\ell-1}) \cap \mathcal{H}) - \text{vol}(\mathbb{L}_j(\mathbf{f}_\ell) \cap \mathcal{H}))^2 \leq \frac{4nl^2}{s^4} (g_\ell - h_\ell)^2 \text{vol}(\mathcal{H})^2,$$

and thus taking  $c_\ell = \frac{4nl^2}{s^4}$  works.

To finish, we note that

$$\begin{aligned}
\sum_{j=1}^n (\text{vol}(\mathbb{L}_j(\mathbf{g}) \cap \mathcal{H}) - \text{vol}(\mathbb{L}_j(\mathbf{h}) \cap \mathcal{H}))^2 &= \sum_{j=1}^n \left[ \sum_{\ell=1}^n (\text{vol}(\mathbb{L}_j(\mathbf{f}_{\ell-1}) \cap \mathcal{H}) - \text{vol}(\mathbb{L}_j(\mathbf{f}_\ell) \cap \mathcal{H})) \right]^2 \\
&\leq n \sum_{j=1}^n \sum_{\ell=1}^n (\text{vol}(\mathbb{L}_j(\mathbf{f}_{\ell-1}) \cap \mathcal{H}) - \text{vol}(\mathbb{L}_j(\mathbf{f}_\ell) \cap \mathcal{H}))^2 \\
&\leq n \sum_{\ell=1}^n \frac{4nl^2}{s^4} (g_\ell - h_\ell)^2 \text{vol}(\mathcal{H})^2 \\
&\leq \frac{4n^2 l^2}{s^4} \left( \sum_{\ell=1}^n (g_\ell - h_\ell)^2 \right) \text{vol}(\mathcal{H})^2
\end{aligned}$$

and thus we obtain the desired result.  $\square$

**Lemma 2.12.** *The function  $\mathcal{E}$  is  $L$ -smooth where  $L \in \text{poly}(n, l, k, \frac{1}{s})$ .*

*Proof.* We will need to prove that for any  $\mathbf{g}, \mathbf{h} \in \mathbb{R}^n$ , we have

$$\|\nabla \mathcal{E}(\mathbf{g}) - \nabla \mathcal{E}(\mathbf{h})\| \leq L \|\mathbf{g} - \mathbf{h}\|$$

for some  $L \in \text{poly}(n, l, k, \frac{1}{s})$ . By Lemma 2.11 applied to each of the  $k$  hyperrectangles  $\mathcal{H}_1, \mathcal{H}_2, \dots, \mathcal{H}_k$ , we note that for any  $1 \leq \ell \leq k$ , we have

$$\sum_{j=1}^n (\text{vol}(\mathbb{L}_j(\mathbf{g}) \cap \mathcal{H}_\ell) - \text{vol}(\mathbb{L}_j(\mathbf{h}) \cap \mathcal{H}_\ell))^2 \leq \frac{4n^2 l^2}{s^4} \left( \sum_{j=1}^n |g_j - h_j|^2 \right) \text{vol}(\mathcal{H}_\ell)^2$$

Finally, we note that

$$\begin{aligned}
\|\nabla \mathcal{E}(\mathbf{g}) - \nabla \mathcal{E}(\mathbf{h})\|^2 &= \sum_{j=1}^n (\nabla \mathcal{E}(\mathbf{g})_j - \nabla \mathcal{E}(\mathbf{h})_j)^2 \\
&= \sum_{j=1}^n \left( \sum_{\ell=1}^k -\gamma_\ell \cdot (\text{vol}(\mathbb{L}_j(\mathbf{g}) \cap \mathcal{H}_\ell) - \text{vol}(\mathbb{L}_j(\mathbf{h}) \cap \mathcal{H}_\ell)) \right)^2 \\
&\leq k \sum_{j=1}^n \sum_{\ell=1}^k \gamma_\ell^2 \cdot (\text{vol}(\mathbb{L}_j(\mathbf{g}) \cap \mathcal{H}_\ell) - \text{vol}(\mathbb{L}_j(\mathbf{h}) \cap \mathcal{H}_\ell))^2 \\
&= k \sum_{\ell=1}^k \gamma_\ell^2 \cdot \left[ \sum_{j=1}^n (\text{vol}(\mathbb{L}_j(\mathbf{g}) \cap \mathcal{H}_\ell) - \text{vol}(\mathbb{L}_j(\mathbf{h}) \cap \mathcal{H}_\ell))^2 \right] \\
&\leq \frac{4n^2 l^2 k}{s^4} \left( \sum_{j=1}^n |g_j - h_j|^2 \right) \left( \sum_{\ell=1}^k \gamma_\ell^2 \text{vol}(\mathcal{H}_\ell)^2 \right) \\
&\leq \frac{4n^2 l^2 k}{s^4} \|\mathbf{g} - \mathbf{h}\|^2 \left( \sum_{\ell=1}^k \gamma_\ell \text{vol}(\mathcal{H}_\ell) \right)^2 = \frac{4n^2 l^2 k}{s^4} \|\mathbf{g} - \mathbf{h}\|^2
\end{aligned}$$

where here we use the fact that  $1 = \int_{\mathbb{R}^l} d\alpha(\mathbf{x}) = \sum_{\ell=1}^k \gamma_\ell \text{vol}(\mathcal{H}_\ell)$ , and thus by picking our constant  $L$  to be

$$L := \frac{2nlk}{s^2} \in \text{poly}\left(n, l, k, \frac{1}{s}\right), \quad (10)$$

we have the desired result.  $\square$

**Remark 2.13.** *We will show in the next section (2.3) that dependence of the Lipschitz constant on the inverse minimum distance between any two points in the reference set is indeed necessary.*

With the lemmas established, we proceed to minimize the energy function using gradient descent. By leveraging a standard convergence guarantee, we can achieve  $\varepsilon$ -accuracy within  $O\left(\frac{L}{\varepsilon}\right)$  time complexity.

**Theorem 2.14** (Corollary 2.1.2 from [Nes14]). *Let  $f$  be convex and  $L$ -smooth on  $\mathbb{R}^n$ . Then, gradient descent with a step size  $\eta = \frac{1}{L}$  ensures*

$$f(\mathbf{x}_k) - f(\mathbf{x}^*) \leq \frac{2L\|\mathbf{x}_0 - \mathbf{x}^*\|^2}{k+4}.$$

However, in our setting, we do not have access to exact gradients and instead rely on noisy gradient estimates obtained from our volume estimation algorithm, and thus we cannot rely on the classical convergence guarantee. Thus, we require a convergence guarantee that accounts for the noisy nature of the gradient estimates. To this end, we consider an inexact gradient descent framework, where  $f \equiv -\mathcal{E}$  is convex and  $L$ -smooth with  $L = \frac{2nlk}{s^2}$ . We will use  $\tilde{\nabla}f(\mathbf{x}_t)$  to stand for a noisy gradient in our algorithm satisfying

$$\tilde{\nabla}f(\mathbf{x}_t) = \nabla f(\mathbf{x}_t) + \mathbf{e}_t,$$

where  $\mathbf{e}_t$  represents the noise introduced in the  $t$ -th gradient estimation. The algorithm begins at  $\mathbf{g}_1 = \mathbf{0}$  and applies inexact gradient descent to the function  $f \equiv -\mathcal{E}$  to maximize the energy  $\mathcal{E}(\mathbf{g})$ , aiming for the optimal value  $\mathbf{g}^*$ . This process generates a sequence of iterates  $\mathbf{g}_1, \mathbf{g}_2, \dots$ , targeting a final iterate  $\mathbf{g}_{\overline{M}}$  after  $\overline{M}$  iterations where  $\overline{M}$  is defined in (12) and we see from the algorithm that  $\overline{M} \leq M$ . Here, we will place the assumption that  $\|\mathbf{e}_t\| \leq \frac{\varepsilon'}{360nD^2}$ .

The value  $\mathcal{E}(\mathbf{g}_{\overline{M}})$  will ultimately provide the accuracy required for our estimates of  $\boldsymbol{\mu}^*$  and  $\sigma^*$ . To achieve this, we select

$$\varepsilon' = 2\varepsilon \cdot \frac{\left[ N \left( \int_{\mathbb{R}^l} \|\mathbf{x}\|^2 d\alpha(\mathbf{x}) \right) - \left\| \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right\|^2 \right]}{N + \frac{1}{D} \left\| \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right\|}, \quad (11)$$

which we will prove to be bounded in terms of our parameters, and we will prove that upon termination of the following inexact gradient descent algorithm, the inequality  $|\mathcal{E}(\mathbf{g}^*) - \mathcal{E}(\mathbf{g}_{\overline{M}})| \leq \varepsilon'$  holds and use this to obtain the desired accuracy guarantee for  $\boldsymbol{\mu}$  and  $\sigma$ . The algorithm is described in Algorithm 1.

Here, we will define

$$M := \frac{4}{\varepsilon'} \cdot 4800n^2D^4L \quad \text{and} \quad \overline{M} := \min \left( M, \min \left\{ t : \|\nabla f(\mathbf{g}_t) + \mathbf{e}_t\| \leq \frac{\varepsilon'}{45nD^2} \right\} \right). \quad (12)$$

---

**Algorithm 1** Inexact Gradient Descent ( $f \equiv -\mathcal{E}$  here)

---

Initialize  $\mathbf{g}_1 = \mathbf{0}$ .

Use volume estimation to compute  $\tilde{\nabla}f(\mathbf{g}_1)$  such that  $\|\mathbf{e}_1\| \leq \frac{\varepsilon'}{360nD^2}$ .

**while**  $\|\tilde{\nabla}f(\mathbf{g}_t)\| > \frac{\varepsilon'}{45nD^2}$  or  $t < M$  **do**

    Update  $\mathbf{g}_{t+1} = \mathbf{g}_t - \frac{1}{L}\tilde{\nabla}f(\mathbf{g}_t)$ .

    Compute  $\tilde{\nabla}f(\mathbf{g}_{t+1})$  with  $\|\mathbf{e}_{t+1}\| \leq \frac{\varepsilon'}{360nD^2}$ .

**end while**

---

**Lemma 2.15.** *The value  $\varepsilon'$  defined by (11) is lower-bounded by  $\frac{\varepsilon}{12}s^2$ .*

*Proof.* We will first argue that the numerator expression  $N \left( \int_{\mathbb{R}^l} \|\mathbf{x}\|^2 d\alpha(\mathbf{x}) \right) - \left\| \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right\|^2$  is translation invariant. Indeed, we note that for any  $\mathbf{c} \in \mathbb{R}^l$ , we have

$$\begin{aligned} N \left( \int_{\mathbb{R}^l} \|\mathbf{x} - \mathbf{c}\|^2 d\alpha(\mathbf{x}) \right) &= N \left( \int_{\mathbb{R}^l} (\|\mathbf{x}\|^2 - 2\mathbf{c}^\top \mathbf{x} + \mathbf{c}^\top \mathbf{c}) d\alpha(\mathbf{x}) \right) \\ &= N \int_{\mathbb{R}^l} \|\mathbf{x}\|^2 d\alpha(\mathbf{x}) - 2N\mathbf{c}^\top \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) + \mathbf{c}^\top \mathbf{c}N^2 \end{aligned}$$

and

$$\begin{aligned} \left\| \int_{\mathbb{R}^l} (\mathbf{x} - \mathbf{c}) d\alpha(\mathbf{x}) \right\|^2 &= \left\| \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right\|^2 - 2 \left( \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right)^\top \left( \int_{\mathbb{R}^l} \mathbf{c} d\alpha(\mathbf{x}) \right) + \left\| \int_{\mathbb{R}^l} \mathbf{c} d\alpha(\mathbf{x}) \right\|^2 \\ &= \left\| \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right\|^2 - 2N\mathbf{c}^\top \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) + \mathbf{c}^\top \mathbf{c}N^2 \end{aligned}$$

and thus

$$N \left( \int_{\mathbb{R}^l} \|\mathbf{x}\|^2 d\alpha(\mathbf{x}) \right) - \left\| \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right\|^2 = N \left( \int_{\mathbb{R}^l} \|\mathbf{x} - \mathbf{c}\|^2 d\alpha(\mathbf{x}) \right) - \left\| \int_{\mathbb{R}^l} (\mathbf{x} - \mathbf{c}) d\alpha(\mathbf{x}) \right\|^2.$$

Therefore, we may choose  $\mathbf{c}$  for which  $\int_{\mathbb{R}^l} (\mathbf{x} - \mathbf{c}) d\alpha(\mathbf{x}) = \mathbf{0}$  and it remains to bound the first term of the numerator of (11) alone. We recall that

$$\begin{aligned} \int_{\mathcal{H}_i} \|\mathbf{x}\|^2 d\mathbf{x} &= \frac{1}{3} \sum_{j=1}^l (b_{i,j}^3 - a_{i,j}^3) \prod_{h \neq j} (b_{i,h} - a_{i,h}) \\ &= \frac{1}{3} \text{vol}(\mathcal{H}_i) \sum_{j=1}^l (b_{i,j}^2 + a_{i,j}^2 + a_{i,j}b_{i,j}) \\ &\geq \frac{1}{12} \text{vol}(\mathcal{H}_i) \sum_{j=1}^l (b_{i,j} - a_{i,j})^2 \geq \frac{1}{12} \text{vol}(\mathcal{H}_i) l s^2 \end{aligned}$$

and thus

$$\int_{\mathbb{R}^l} \|\mathbf{x}\|^2 d\alpha(\mathbf{x}) = \sum_{i=1}^k \gamma_i \int_{\mathcal{H}_i} \|\mathbf{x}\|^2 d\mathbf{x} \geq \frac{1}{12} l s^2 \cdot \sum_{i=1}^k \gamma_i \text{vol}(\mathcal{H}_i) \geq \frac{1}{12} l s^2 N.$$

We thus obtain the numerator is bounded from below in terms of function of the parameters. Now, we have the denominator as

$$N + \frac{1}{D} \left\| \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right\| \leq N + \left\| \int_{\mathbb{R}^l} \mathbf{1} d\alpha(\mathbf{x}) \right\| = N + \sqrt{l \left( \int_{\mathbb{R}^l} 1 d\alpha(\mathbf{x}) \right)^2} = N + N\sqrt{l} \leq 2Nl.$$

Therefore,

$$\varepsilon' \geq 2\varepsilon \cdot \frac{ls^2N/12}{2Nl} \geq \frac{1}{12}\varepsilon s^2$$

which is as desired form.  $\square$

We begin by revisiting (7) and observing that for any vector  $\mathbf{g}$  such that  $\sum_i g_i \neq 0$ , we can define its centered counterpart as  $\bar{\mathbf{g}} := \mathbf{g} - (\frac{1}{n} \sum_i g_i) \mathbf{1}$ , which preserves the cost, i.e.,  $\mathcal{E}(\bar{\mathbf{g}}) = \mathcal{E}(\mathbf{g})$ , while ensuring that  $\sum_i \bar{g}_i = 0$ . Consequently, any solution  $\mathbf{g}$  can be mapped to a solution  $\bar{\mathbf{g}}$  within the subspace

$$\mathcal{G}_0 := \left\{ \mathbf{g} \in \mathbb{R}^n : \sum_{i=1}^n g_i = 0 \right\}$$

without altering the cost. This observation motivates us to focus exclusively on solutions within the subspace  $\mathcal{G}_0$ .

To analyze this, we begin by proving the following claim about  $\mathbf{g}$ , which allows us to ensure the boundedness of  $\mathbf{g}$  when restricted to the subspace  $\mathcal{G}_0$ .

**Lemma 2.16.** *If  $\mathbf{g}$  is the optimizer of  $\mathcal{E}$ , then*

$$|g_i - g_j| \leq 16nD^2, \quad \forall 1 \leq i < j \leq n.$$

*In particular, under the restriction to the subspace  $\mathcal{G}_0$ , the optimal vector  $\mathbf{g}$  is bounded by  $16nD^2$  in the  $\infty$ -norm.*

*Proof.* Suppose  $\mathbb{L}_i(\mathbf{g})$  and  $\mathbb{L}_j(\mathbf{g})$  are distinct Laguerre cells, i.e.,  $i \neq j$ . We first note that for any  $j$ , there exists an  $\mathbf{x} \in \mathbb{L}_j(\mathbf{g})$  for which  $\pi(\mathbf{x}, \mathbf{y}_j) > 0$ . To show this, observe that  $\int_{\mathbb{R}^l} d\pi(\mathbf{x}, \mathbf{y}_j) = b_j = \frac{1}{n} > 0$ , and thus there exists  $\mathbf{x}$  for which  $d\alpha(\mathbf{x}) = \sum_{\ell=1}^n d\pi(\mathbf{x}, \mathbf{y}_\ell) > 0$ . Therefore, by complementary slackness on  $\pi$  and  $\mathbf{g}, h$  and the fact that  $d\pi^*(\mathbf{x}, \mathbf{y}_j) > 0$ , we have

$$\|\mathbf{x} - \mathbf{y}_j\|^2 - g_j^* - h^*(\mathbf{x}) = 0,$$

while dual feasibility gives us  $\|\mathbf{x} - \mathbf{y}_{j'}\|^2 - g_{j'}^* - h^*(\mathbf{x}) \geq 0$  which gives us  $\|\mathbf{x} - \mathbf{y}_{j'}\|^2 - g_{j'}^* \geq \|\mathbf{x} - \mathbf{y}_j\|^2 - g_j^*$ , i.e.  $\mathbf{x} \in \mathbb{L}_j(\mathbf{g})$ . This shows that each Laguerre cell intersects with at least one hyperrectangle  $\mathcal{H}_1, \dots, \mathcal{H}_k$ , so let  $\mathbf{z}_i \in \mathbb{L}_i(\mathbf{g}) \cap \bigcup_{p=1}^k \mathcal{H}_p$  and  $\mathbf{z}_j \in \mathbb{L}_j(\mathbf{g}) \cap \bigcup_{p=1}^k \mathcal{H}_p$  and in particular,  $\|\mathbf{z}_j\| \leq D$ .

Consider the function  $\mathbf{f} : [0, 1] \rightarrow \mathbb{R}^l$  defined by  $\mathbf{f}(\alpha) = (1 - \alpha)\mathbf{z}_i + \alpha\mathbf{z}_j$ . Let  $j, k$  be indices of two Laguerre cells that share a point. We denote  $B_{j,k}$  denote the boundary between Laguerre cells  $\mathbb{L}_j(\mathbf{g})$  and  $\mathbb{L}_k(\mathbf{g})$ . For any  $\mathbf{x} \in B_{j,k}$ , we have:

$$\|\mathbf{x} - \mathbf{y}_j\|^2 - g_j = \|\mathbf{x} - \mathbf{y}_k\|^2 - g_k \implies g_j - g_k = \|\mathbf{x} - \mathbf{x}_j\|^2 - \|\mathbf{x} - \mathbf{y}_k\|^2.$$

Since  $\mathbf{f}(0) = \mathbf{z}_i \in \mathbb{L}_i(\mathbf{g})$  and  $\mathbf{f}(1) = \mathbf{z}_j \in \mathbb{L}_j(\mathbf{g})$ , and Laguerre cells are convex, we can find a sequence of indices  $i = i_1, \dots, i_\ell = j$  and values  $\alpha_1, \dots, \alpha_{\ell-1} \in (0, 1)$  with  $2 \leq \ell \leq n$  such that  $\mathbf{f}(\alpha_p) \in B_{i_p, i_{p+1}}$  for all  $1 \leq p \leq \ell - 1$ . For each  $1 \leq p \leq \ell - 1$ , since  $\mathbf{f}(\alpha_p) \in B_{i_p, i_{p+1}}$ , it follows that:

$$\begin{aligned} g_{i_p} - g_{i_{p+1}} &= \|\mathbf{f}(\alpha_p) - \mathbf{y}_{i_p}\|^2 - \|\mathbf{f}(\alpha_p) - \mathbf{y}_{i_{p+1}}\|^2 \\ &\leq \|\mathbf{f}(\alpha_p) - \mathbf{y}_{i_p}\|^2 \\ &= \|(1 - \alpha_p)(\mathbf{z}_i - \mathbf{y}_{i_p}) + \alpha_p(\mathbf{z}_j - \mathbf{y}_{i_p})\|^2 \\ &\leq 2(\|\mathbf{z}_i - \mathbf{y}_{i_p}\|^2 + \|\mathbf{z}_j - \mathbf{y}_{i_p}\|^2). \end{aligned}$$

Summing over all  $1 \leq p \leq \ell - 1$ , we obtain:

$$g_i - g_j \leq 2 \sum_{p=1}^{\ell-1} (\|\mathbf{z}_i - \mathbf{y}_{i_p}\|^2 + \|\mathbf{z}_j - \mathbf{y}_{i_p}\|^2) \leq 2(\ell-1) \cdot \left( \max_{1 \leq p \leq n} \|\mathbf{z}_i - \mathbf{y}_p\|^2 + \max_{1 \leq p \leq n} \|\mathbf{z}_j - \mathbf{y}_p\|^2 \right) \leq 16nD^2.$$

□

Within  $\mathcal{G}_0$ , we have already established that  $\mathbf{g}$  is bounded and thus by running gradient descent algorithm starting on  $\mathbf{g}_0 = \mathbf{0}$ , we hope to find a near-extremum value for  $-\mathcal{E}$  inside the subspace  $\mathcal{G}_0$ . Our next step is to prove that the gradient descent iterates are confined to a bounded set. Although the following argument generalizes to any  $\mathbf{b}$  in our setup, for simplicity, we will focus on the special case relevant to our original parameter estimation analysis, i.e. the case where  $b_i = \frac{1}{n}$  for all  $1 \leq i \leq n$ .

**Lemma 2.17.** *Assume  $b_i = \frac{1}{n}$  for all  $1 \leq i \leq n$ . Then the level set  $S := \{\mathbf{g} \in \mathcal{G}_0 \mid -\mathcal{E}(\mathbf{g}) \leq -\mathcal{E}(\mathbf{0})\}$  is entirely contained within the ball  $B(\mathbf{0}, 20nD^2)$ .*

*Proof.* Since  $\langle \mathbf{g}, \mathbf{b} \rangle = 0$  for any  $\mathbf{g} \in \mathcal{G}_0$ , the energy function can be reduced to

$$\mathcal{E}(\mathbf{g}) = \sum_{j=1}^n \int_{\mathbb{L}_j(\mathbf{g})} (\|\mathbf{x} - \mathbf{y}_j\|^2 - g_j) d\alpha(\mathbf{x}).$$

It follows immediately that  $-\mathcal{E}(\mathbf{0}) \leq 0$ . We may reorder the components of  $\mathbf{g}$  such that  $g_1 \geq g_2 \geq \dots \geq g_n$ . We will first start by showing that the following summation

$$\sum_{j=1}^n \int_{\mathbb{L}_j(\mathbf{g})} \|\mathbf{x} - \mathbf{y}_j\|^2 d\alpha(\mathbf{x})$$

is bounded above by a constant independent of  $\mathbf{g}$ . For any  $\mathbf{x} \in \mathcal{H} := \bigcup_i \mathcal{H}_i$  and any  $1 \leq j \leq n$ , it holds that  $\|\mathbf{x} - \mathbf{y}_j\|^2 \leq 4D^2$ . Thus, we have

$$\sum_{j=1}^n \int_{\mathbb{L}_j(\mathbf{g})} \|\mathbf{x} - \mathbf{y}_j\|^2 d\alpha(\mathbf{x}) \leq 4D^2 \sum_{j=1}^n \int_{\mathbb{L}_j(\mathbf{g})} 1 d\alpha(\mathbf{x}) = 4D^2 \cdot \sum_{\ell} \gamma_{\ell} \text{vol}(\mathcal{H}_{\ell}) = 4D^2,$$

which is a constant independent of  $\mathbf{g}$ .

Next, observe that if  $r > 1$  and  $g_r < g_1 - 8D^2$ , then the region  $\mathbb{L}_r(\mathbf{g})$  does not meet a hyperrectangle. To be more precise, we see that if  $g_1 - g_r > 8D^2$ , then

$$g_1 - g_r > \|\mathbf{x} - \mathbf{y}_1\|^2 - \|\mathbf{x} - \mathbf{y}_r\|^2 \quad \forall \mathbf{x} \in \mathcal{H}.$$

This implies that no elements of the hyperrectangle can intersect with  $\mathbb{L}_r(\mathbf{g})$ , as desired. We want to prove that the level set of  $-\mathcal{E}(\mathbf{0})$  is entirely contained inside  $B(\mathbf{0}, 20nD^2)$ . To prove this, we just need to note that any  $\mathbf{g}$  such that  $\mathcal{E}(\mathbf{g}) \geq \mathcal{E}(\mathbf{0})$  must satisfy  $g_1 \leq 20nD^2$ . We see that if  $g_1 > 20nD^2$ , then  $g_n < 0$  and thus we have

$$\begin{aligned} 0 &= g_1 + g_2 + \dots + g_n \\ &> 20nD^2 + ng_n \end{aligned}$$

and thus  $g_n < -20D^2$ , which implies  $g_1 - g_n > 20(n+1)D^2$ . Thus we have

$$\begin{aligned}\mathcal{E}(\mathbf{g}) &= \sum_{j=1}^n \int_{\mathbb{L}_j(\mathbf{g})} \|\mathbf{x} - \mathbf{y}_j\|^2 d\alpha(\mathbf{x}) + \sum_{j=1}^n \int_{\mathbb{L}_j(\mathbf{g})} -g_j d\alpha(\mathbf{x}) \\ &\leq 4D^2 + \sum_{j=1}^n \int_{\mathbb{L}_j(\mathbf{g})} -g_j d\alpha(\mathbf{x}).\end{aligned}$$

Let  $r$  be such that  $g_r \geq g_1 - 8D^2$  and  $g_{r+1} < g_1 - 8D^2$ . Such an  $r$  must exist since  $g_1 - g_n > 20(n+1)D^2$  and  $g_1 \geq g_1 - 8D^2$ . Now, this implies that  $\mathbb{L}_{r+1}(\mathbf{g}) \cap \mathcal{H} = \cdots = \mathbb{L}_n(\mathbf{g}) \cap \mathcal{H} = \emptyset$  and thus the above expression reduces to

$$\begin{aligned}4D^2 + \sum_{j=1}^r \int_{\mathbb{L}_j(\mathbf{g})} -g_j d\alpha(\mathbf{x}) &\leq 4D^2 + \sum_{j=1}^r \int_{\mathbb{L}_j(\mathbf{g})} (8D^2 - g_1) d\alpha(\mathbf{x}) \\ &\leq 4D^2 + \sum_{j=1}^r \int_{\mathbb{L}_j(\mathbf{g})} (8D^2 - 20nD^2) d\alpha(\mathbf{x}) \\ &= 4D^2 + 8D^2 - 20nD^2 < 0 \leq \mathcal{E}(\mathbf{0})\end{aligned}$$

Therefore, this implies that if  $\mathbf{g}$  is such that  $\mathcal{E}(\mathbf{g}) \geq \mathcal{E}(\mathbf{0})$  must have  $g_1 \leq 20nD^2$ .  $\square$

This ensures that if the initial iterate  $\mathbf{g}_1$  is in  $S$ , then all subsequence iterates  $\mathbf{g}_t$  will remain within  $S$ , implying that we have  $\|\mathbf{g}_t\| \leq 20nD^2$  for all  $t \geq 1$ .

In our inexact gradient analysis, where we set  $f \equiv -\mathcal{E}$ , the descent step follows a descent inequality as long as the gradient is not too small.

**Lemma 2.18.** *If the algorithm has not terminated at time  $t$ , then  $\|\mathbf{e}_t\| < \frac{1}{7}\|\nabla f(\mathbf{g}_t)\|$ .*

*Proof.* Since the algorithm has not terminated on time  $t$ , we have  $\|\tilde{\nabla} f(\mathbf{g}_t)\| > \frac{\epsilon'}{45nD^2}$ . This implies that as this inexact gradient is computed with error  $\|\mathbf{e}_t\| \leq \frac{\epsilon'}{360nD^2}$ , we have

$$\|\nabla f(\mathbf{g}_t)\| = \left\| \tilde{\nabla} f(\mathbf{g}_t) - \mathbf{e}_t \right\| \geq \|\tilde{\nabla} f(\mathbf{g}_t)\| - \|\mathbf{e}_t\| > \frac{7\epsilon'}{360nD^2} \geq 7\|\mathbf{e}_t\|,$$

as desired.  $\square$

**Claim 2.19.** *For any  $1 \leq t \leq \overline{M} - 1$ , where  $\overline{M}$  is defined as (12),*

$$f(\mathbf{g}_{t+1}) \leq f(\mathbf{g}_t) - \frac{1}{3L}\|\nabla f(\mathbf{g}_t)\|^2.$$

*Here,  $L$  is the smoothness constant in Equation (10).*

*Proof.* Using the smoothness of  $f$  and the fact that  $\|\mathbf{e}_t\| < \frac{1}{7}\|\nabla f(\mathbf{g}_t)\|$  since the algorithm has not

terminated at time  $t$ , where  $1 \leq t \leq \overline{M} - 1$ , we have:

$$\begin{aligned}
f(\mathbf{g}_{t+1}) &\leq f(\mathbf{g}_t) + \langle \nabla f(\mathbf{g}_t), \mathbf{g}_{t+1} - \mathbf{g}_t \rangle + \frac{L}{2} \|\mathbf{g}_{t+1} - \mathbf{g}_t\|^2 \\
&= f(\mathbf{g}_t) - \left\langle \nabla f(\mathbf{g}_t), \frac{1}{L}(\nabla f(\mathbf{g}_t) + \mathbf{e}_t) \right\rangle + \frac{1}{2L} \|\nabla f(\mathbf{g}_t) + \mathbf{e}_t\|^2 \\
&= f(\mathbf{g}_t) - \frac{1}{2L} \|\nabla f(\mathbf{g}_t)\|^2 + \frac{1}{2L} \|\mathbf{e}_t\|^2 \\
&\leq f(\mathbf{g}_t) - \frac{1}{3L} \|\nabla f(\mathbf{g}_t)\|^2.
\end{aligned}$$

□

We now derive an upper bound on the difference between the objective function evaluated at the current iterate and its optimal value. Given that the subsequence of iterates  $\mathbf{g}_t$  satisfies  $\|\mathbf{g}_t\| \leq 20nD^2$  for all  $t \geq 1$  and thus  $\|\mathbf{g}^*\| \leq 20nD^2$ , it follows from the subgradient inequality that

$$f(\mathbf{g}_t) - f(\mathbf{g}^*) \leq \|\nabla f(\mathbf{g}_t)\| \cdot \|\mathbf{g}_t - \mathbf{g}^*\| \leq 40nD^2 \cdot \|\nabla f(\mathbf{g}_t)\|, \quad \forall t \geq 1, \quad (13)$$

where  $\mathbf{g}^*$  denotes the maximizer of  $\mathcal{E}$  (minimizer of  $f$ ).

**Lemma 2.20.** *For all  $2 \leq t \leq \overline{M}$ , where  $\overline{M}$  is defined as (12), the following inequality holds:*

$$f(\mathbf{g}_t) - f(\mathbf{g}^*) \leq \frac{4}{t} \cdot 4800n^2D^4L.$$

*Proof.* We first recall the recursive inequality for the inexact gradient descent we obtained on Lemma 2.19:

$$f(\mathbf{g}_{t+1}) - f(\mathbf{g}^*) \leq (f(\mathbf{g}_t) - f(\mathbf{g}^*)) - \frac{1}{3L} \|\nabla f(\mathbf{g}_t)\|^2, \quad \forall 1 \leq t \leq \overline{M} - 1.$$

Now, we can apply Lemma 4 from [KV17] to the sequence  $\omega_t = f(\mathbf{g}_t)$  converging to  $\omega^* = f(\mathbf{g}^*)$  as  $t \rightarrow \infty$ . Here, we remark that we may imagine an analysis of fictitious algorithm that satisfies the inequality

$$f(\mathbf{g}_{t+1}) - f(\mathbf{g}_t) \leq -c \|\nabla f(\mathbf{g}_t)\|^2$$

for some constant  $c > 0$  on every iteration. This fictitious algorithm operates as follows: it uses our inexact gradient descent for iterations 1 to  $\overline{M} - 1$  and switches to exact gradient descent from iteration  $\overline{M}$  onward.

This sequence  $\omega_t$  we have constructed is decreasing and satisfies:

$$\omega_t - \omega_{t+1} \geq \frac{1}{3L} \|\nabla f(\mathbf{g}_t)\|^2 \geq \frac{1}{4800n^2D^4L} (f(\mathbf{g}_t) - f(\mathbf{g}^*))^2,$$

as we have  $f(\mathbf{g}_t) - f(\mathbf{g}^*) \leq 40nD^2 \cdot \|\nabla f(\mathbf{g}_t)\|$  by subgradient inequality. We further note that

$$f(\mathbf{g}_1) - f(\mathbf{g}^*) \leq 40nD^2 \cdot \|\nabla f(\mathbf{g}_1)\| = 40nD^2 \|\nabla f(\mathbf{g}_1) - \nabla f(\mathbf{g}^*)\| \leq 40nD^2L \|\mathbf{g}_1 - \mathbf{g}^*\| \leq 800n^2D^4L$$

Thus, we can define  $\mu := 4800n^2D^4L$  which allows us to bound the difference between the sequence and the optimal value:

$$\omega_t - \omega^* \leq \frac{4\mu}{t}, \quad \forall t = 2, \dots, \overline{M}.$$

□

**Lemma 2.21.** *If Algorithm 1 terminates at time  $\overline{M}$ , then  $f(\mathbf{g}_{\overline{M}}) - f(\mathbf{g}^*) \leq \varepsilon'$ .*

*Proof.* We note that there are two possible condition of termination. For the first case, in which case we have  $\|\tilde{\nabla}f(\mathbf{g}_{\overline{M}})\| < \frac{1}{45nD^2}$ , we obtain

$$\|\nabla f(\mathbf{g}_{\overline{M}})\| \leq \|\mathbf{e}_M\| + \|\tilde{\nabla}f(\mathbf{g}_{\overline{M}})\| \leq \frac{\varepsilon'}{40nD^2}.$$

In conclusion, by (13) we have

$$f(\mathbf{g}_{\overline{M}}) - f(\mathbf{g}^*) \leq 40nD^2 \|\nabla f(\mathbf{g}_{\overline{M}})\| \leq \varepsilon',$$

as desired. Otherwise, for the second case of termination when  $\overline{M} = M$ , we note that from (12) and 2.20,

$$f(\mathbf{g}_M) - f(\mathbf{g}^*) \leq \frac{4}{M} \cdot 4800n^2D^4L \leq \varepsilon'$$

□

**Claim 2.22.** *The running time of Algorithm 1 is polynomial in  $\text{poly}\left(n, l, k, D, \frac{1}{s}, \frac{1}{\varepsilon}, \log \frac{1}{\eta}\right)$ .*

*Proof.* By the design of the algorithm, this algorithm runs at most

$$M = \frac{4}{\varepsilon'} \cdot 4800n^2D^4L$$

time. At each of the algorithm iteration, it must be the case that  $\|\tilde{\nabla}f(\mathbf{g}_t)\| > \frac{\varepsilon'}{45nD^2}$ . We note that  $\nabla\mathcal{E}(\mathbf{g}_t)$  can be computed as

$$\nabla\mathcal{E}(\mathbf{g}_t)_j = \sum_{\ell=1}^k -\gamma_\ell \cdot \text{vol}(\mathbb{L}_j(\mathbf{g}_t) \cap \mathcal{H}_\ell) + b_j, \quad 1 \leq j \leq \ell.$$

We will now use our volume computation algorithm to obtain an estimate  $v_{t,h}$  for  $\text{vol}(\mathbb{L}_j(\mathbf{g}_t) \cap \mathcal{H}_h)$  within  $\frac{\bar{\varepsilon}}{\sqrt{n}}$  accuracy, where  $\bar{\varepsilon} := \frac{\varepsilon'}{360nD^2}$  for each  $1 \leq t \leq \overline{M}$  and  $1 \leq h \leq k$ , i.e.,

$$|v_{t,h} - \text{vol}(\mathbb{L}_j(\mathbf{g}_t) \cap \mathcal{H}_h)| \leq \frac{\bar{\varepsilon}}{\sqrt{n}} \cdot \text{vol}(\mathbb{L}_j(\mathbf{g}_t) \cap \mathcal{H}_h) \leq \frac{\bar{\varepsilon}}{\sqrt{n}} \cdot \text{vol}(\mathcal{H}_h)$$

and let us consider the noisy gradient estimate  $v_{t,1}, \dots, v_{t,k}$  as follow:

$$\tilde{\nabla}\mathcal{E}(\mathbf{g}_t)_j = \sum_{\ell=1}^k -\gamma_\ell \cdot v_{t,\ell} + b_j, \quad 1 \leq j \leq l.$$

Therefore, for this choice of  $\tilde{\nabla}\mathcal{E}(\mathbf{g}_t)$ , we must have

$$\begin{aligned}
\|\tilde{\nabla}\mathcal{E}(\mathbf{g}_t) - \nabla\mathcal{E}(\mathbf{g}_t)\|^2 &= \sum_{j=1}^n |\tilde{\nabla}\mathcal{E}(\mathbf{g}_t)_j - \nabla\mathcal{E}(\mathbf{g}_t)_j|^2 \\
&= \sum_{j=1}^n \left| \sum_{\ell=1}^k \gamma_\ell (v_{t,\ell} - \text{vol}(\mathbb{L}_j(\mathbf{g}_t) \cap \mathcal{H}_\ell)) \right|^2 \\
&\leq \sum_{j=1}^n \left( \sum_{\ell=1}^k \gamma_\ell \cdot |v_{t,\ell} - \text{vol}(\mathbb{L}_j(\mathbf{g}_t) \cap \mathcal{H}_\ell)| \right)^2 \\
&\leq \sum_{j=1}^n \left( \sum_{\ell=1}^k \gamma_\ell \cdot \frac{\bar{\varepsilon}}{\sqrt{n}} \cdot \text{vol}(\mathcal{H}_\ell) \right)^2 \\
&= \frac{(\bar{\varepsilon})^2}{n} \sum_{j=1}^n \left( \sum_{\ell=1}^k \gamma_\ell \text{vol}(\mathcal{H}_\ell) \right)^2 \\
&\leq (\bar{\varepsilon})^2
\end{aligned}$$

and thus we have  $\|\tilde{\nabla}\mathcal{E}(\mathbf{g}_t) - \nabla\mathcal{E}(\mathbf{g}_t)\| \leq \bar{\varepsilon}$ . By our volume estimation oracle, we can obtain an  $\bar{\varepsilon}$ -estimate of  $\nabla\mathcal{E}(\mathbf{g}_t)$  using  $k$  calls to volume estimation. This process requires  $O\left(\text{poly}\left(n, \frac{1}{\bar{\varepsilon}}, \log \frac{1}{\eta'}\right)\right)$  separation oracle calls, where  $\eta' = \frac{\eta}{kM}$ . Applying the union bound, the probability that all  $kM$  separation oracles yield correct volume estimations is at least

$$\begin{aligned}
&\mathbb{P}[\text{All } kM \text{ oracles yield correct volume estimation}] \\
&= 1 - \mathbb{P}[\text{At least one oracle yields incorrect volume estimation}] \\
&\geq 1 - kM \cdot \eta' = 1 - \eta.
\end{aligned}$$

Thus, the desired probability bound is achieved.

Additionally, each separation oracle call operates in  $O(nl)$  time. Performing this procedure for each  $1 \leq i \leq M$  results in a total of

$$\sum_{i=1}^M O\left(\text{poly}\left[n, l, \frac{1}{\bar{\varepsilon}}, \log \frac{1}{\eta'}\right]\right) = O\left(\text{poly}\left[n, k, M, \frac{1}{\bar{\varepsilon}}, \log \frac{1}{\eta'}\right]\right)$$

running time. Here, we notice that we have

$$L = \frac{2nlk}{s^2} \quad \text{and} \quad M = \frac{4}{\varepsilon'} \cdot 4800n^2 D^4 L \in O\left(\text{poly}\left[n, l, k, D, \frac{1}{\varepsilon}, \frac{1}{s}\right]\right).$$

Finally, we also note that  $\log \frac{1}{\eta'} = \log \frac{kM}{\eta} \in O\left(kM \log \frac{1}{\eta}\right) = O\left(\text{poly}\left[n, l, k, D, \frac{1}{\varepsilon}, \frac{1}{s}, \log \frac{1}{\eta}\right]\right)$ . This gives us  $O\left(\text{poly}\left[n, l, k, D, \frac{1}{\varepsilon}, \frac{1}{s}, \log \frac{1}{\eta}\right]\right)$  time to obtain  $\mathbf{g}_M$ .

We recall that  $p^* = \mathcal{E}(\mathbf{g}^*)$  gives us the optimal solution to the dual program, and thus giving us an estimate  $\rho := \frac{1}{2} \left[ \mathcal{E}(\mathbf{g}_M) - \int_{\mathbb{R}^l} \|\mathbf{x}\|^2 d\alpha(\mathbf{x}) - \sum_{j=1}^n b_j \|\mathbf{y}_j\|^2 \right]$  which can be computed exactly, for which we have

$$2 \left| \int_{\mathbb{R}^l} \sum_{j=1}^n \mathbf{x}^\top \mathbf{y}_j d\pi(\mathbf{x}, \mathbf{y}_j) - \rho \right| = |\mathcal{E}(\mathbf{g}_M) - \mathcal{E}(\mathbf{g}^*)| \leq \varepsilon'$$

from Lemma 2.21 and thus by our choice of  $\varepsilon'$ , we have

$$\left| \int_{\mathbb{R}^l} \sum_{j=1}^n \mathbf{x}^\top \mathbf{y}_j d\pi(\mathbf{x}, \mathbf{y}_j) - \rho \right| \leq \varepsilon \cdot \frac{\left[ N \left( \int_{\mathbb{R}^l} \|\mathbf{x}\|^2 d\alpha(\mathbf{x}) \right) - \left\| \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right\|^2 \right]}{N + \frac{1}{D} \left\| \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right\|}$$

Therefore, by considering

$$\begin{aligned} \hat{\sigma} &= \frac{N\rho - \left( \sum_{j=1}^n b_j \mathbf{y}_j \right)^\top \left( \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right)}{N \left( \int_{\mathbb{R}^l} \|\mathbf{x}\|^2 d\alpha(\mathbf{x}) \right) - \left\| \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right\|^2} \\ \hat{\boldsymbol{\mu}} &= \frac{\hat{\sigma} \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) - \sum_{j=1}^n b_j \mathbf{y}_j}{N}, \end{aligned}$$

we thus obtain that

$$\begin{aligned} |\hat{\sigma} - \sigma^*| &= \frac{N}{N \left( \int_{\mathbb{R}^l} \|\mathbf{x}\|^2 d\alpha(\mathbf{x}) \right) - \left\| \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right\|^2} \left| \int_{\mathbb{R}^l} \sum_{j=1}^n \mathbf{x}^\top \mathbf{y}_j d\pi(\mathbf{x}, \mathbf{y}_j) - \rho \right| \\ &\leq \varepsilon \\ \|\hat{\boldsymbol{\mu}} - \boldsymbol{\mu}^*\| &= \frac{1}{N} |\hat{\sigma} - \sigma^*| \left\| \int_{\mathbb{R}^l} \mathbf{x} d\alpha(\mathbf{x}) \right\| \\ &\leq \varepsilon D, \end{aligned}$$

as desired. □

□

### 2.3 Necessity of Parameters in Smoothness Constants

In this section, we will show that the established Lipschitz constant necessarily depends on the inverse of both the closest separation between two sample points and the minimum width of the hyperrectangles in the source distribution, as follow:

**Minimum separation between two sample points:** Fix  $m \in \mathbb{N}$ . Consider the following setup where we have  $l = 1, k = 1$ ,  $\mathbf{g}_m = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$ ,  $\mathbf{g}'_m = \begin{pmatrix} 0 \\ \frac{1}{m} \end{pmatrix}$  and define  $y_{1,m}, y_{2,m} \in \mathbb{R}$ , where  $y_{1,m} = -\frac{1}{m}, y_{2,m} = \frac{1}{m}$  where the corresponding hyperrectangle  $\mathcal{H}$  in the source distribution is  $[-1, 1]$  with weight  $\gamma = \frac{1}{2}$ . We note that for any fixed  $m \geq 1$ , we can easily verify that the Laguerre cells are

$$\begin{aligned} \mathbb{L}_1(\mathbf{g}_m) &= \{x \in \mathbb{R} : x \leq 0\} \\ \mathbb{L}_2(\mathbf{g}_m) &= \{x \in \mathbb{R} : x \geq 0\} \\ \mathbb{L}_1(\mathbf{g}'_m) &= \left\{ x \in \mathbb{R} : x \leq -\frac{1}{4} \right\} \\ \mathbb{L}_2(\mathbf{g}'_m) &= \left\{ x \in \mathbb{R} : x \geq -\frac{1}{4} \right\} \end{aligned}$$

and thus  $\|\nabla \mathcal{E}(\mathbf{g}_m) - \nabla \mathcal{E}(\mathbf{g}'_m)\| \neq 0$  is independent of  $m$  for any  $m \geq 1$ , while  $\|\mathbf{g}_m - \mathbf{g}'_m\| \rightarrow 0$  when  $m \rightarrow \infty$ . This shows that when  $m = \frac{2}{|y_{1,m} - y_{2,m}|} \rightarrow \infty$ ,  $\frac{\|\nabla \mathcal{E}(\mathbf{g}_m) - \nabla \mathcal{E}(\mathbf{g}'_m)\|}{\|\mathbf{g}_m - \mathbf{g}'_m\|} \rightarrow \infty$  as well, and

thus this shows that  $L \rightarrow \infty$  when  $m \rightarrow \infty$ .

**Minimum width of the hyperrectangles in the source distribution:** Fix  $m \in \mathbb{N}$ . Let  $l = 2, k = 1, \mathbf{g}_m = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \mathbf{g}'_m = \begin{pmatrix} 0 \\ \frac{1}{m} \end{pmatrix}$  and define  $\mathbf{y}_1, \mathbf{y}_2 \in \mathbb{R}^2$  such that  $\mathbf{y}_1 = \begin{pmatrix} -1 \\ 0 \end{pmatrix}, \mathbf{y}_2 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$  where the corresponding hyperrectangle  $\mathcal{H}$  in the source distribution is  $[-\frac{1}{m}, 0] \times [0, m]$  with weight  $\gamma = 1$ . For any fixed  $m \geq 1$ , we can easily verify that the Laguerre cells are

$$\begin{aligned} \mathbb{L}_1(\mathbf{g}_m) &= \{\mathbf{x} \in \mathbb{R}^2 : x_1 \leq 0\} \\ \mathbb{L}_2(\mathbf{g}_m) &= \{\mathbf{x} \in \mathbb{R}^2 : x_1 \geq 0\} \\ \mathbb{L}_1(\mathbf{g}'_m) &= \left\{ \mathbf{x} \in \mathbb{R}^2 : x_1 \leq -\frac{1}{4m} \right\} \\ \mathbb{L}_2(\mathbf{g}'_m) &= \left\{ \mathbf{x} \in \mathbb{R}^2 : x_1 \geq -\frac{1}{4m} \right\} \end{aligned}$$

Therefore, for any  $m \geq 1$ , we have

$$\|\nabla \mathcal{E}(\mathbf{g}_m) - \nabla \mathcal{E}(\mathbf{g}'_m)\|^2 = \sum_{j=1}^2 (\text{vol}(\mathbb{L}_j(\mathbf{g}_m) \cap \mathcal{H}) - \text{vol}(\mathbb{L}_j(\mathbf{g}'_m) \cap \mathcal{H}))^2 = \frac{1}{8}$$

independent of  $m$ , while  $\|\mathbf{g}_m - \mathbf{g}'_m\| \rightarrow 0$  when  $m \rightarrow \infty$ . This shows that when  $m = \frac{1}{\xi} \rightarrow \infty$ , where  $\xi$  is the minimum width of the hyperrectangle, then we also have  $\frac{\|\nabla \mathcal{E}(\mathbf{g}_m) - \nabla \mathcal{E}(\mathbf{g}'_m)\|}{\|\mathbf{g}_m - \mathbf{g}'_m\|} \rightarrow \infty$  as well, and thus this shows that  $L \rightarrow \infty$  when  $m \rightarrow \infty$ .

### 3 Hardness of Finding a Single Optimal Center in MLE

In this section, we present our main hardness result, highlighting a key distinction between the Wasserstein distance and Maximum Likelihood Estimation (MLE). Specifically, we demonstrate that the problem of finding a single optimal center is NP-hard for MLE, whereas it is solvable in polynomial time for the Wasserstein metric as shown in the previous section.

**Problem Setup.** Given an unknown parameter  $\boldsymbol{\theta}$  of some distribution  $D \equiv \Omega(\mathbf{y}; \boldsymbol{\theta})$  with its associated probability density function  $f(\mathbf{y}) = f_0(\mathbf{y} - \boldsymbol{\theta})$  for some probability density function  $f_0$ , and let  $\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_n \in \mathbb{R}^l$  be  $n$  sample points from  $D$ . We would like to estimate  $\boldsymbol{\theta}$  using maximum likelihood, i.e. we choose  $\boldsymbol{\theta} := \boldsymbol{\theta}^*$  such that

$$\boldsymbol{\theta}^* := \arg \max_{\boldsymbol{\theta} \in \mathbb{R}^l} \prod_{i=1}^n f(\mathbf{y}_i; \boldsymbol{\theta}) = \arg \max_{\boldsymbol{\theta} \in \mathbb{R}^l} \prod_{i=1}^n f_0(\mathbf{y}_i - \boldsymbol{\theta})$$

Our main result is as follows.

**Theorem 3.1.** *Given the problem setup in the case that  $f_0$  is a piecewise constant function on a finite union of hyperrectangles, it is NP-hard to determine whether a  $\boldsymbol{\theta}$  exists for which the likelihood is nonzero.*

*Proof.* The construction is based on the 3-SAT problem, a well-known NP-hard problem. Consider  $l$  variables denoted as  $a_1, \dots, a_l$ , and consider a Boolean formula  $\mathcal{A}_1 \wedge \mathcal{A}_2 \wedge \dots \wedge \mathcal{A}_n$  with  $n$  clauses, each having exactly three literals. We may without loss of generality assume that no clause contains

the same variable more than once. We also assume without loss of generality that every variable appears in at least one clause. Now, we proceed to create an MLE problem based on the given Boolean formula.

Consider  $\mathbf{y}_1, \dots, \mathbf{y}_n \in \mathbb{R}^l$  such that  $\mathbf{y}_\ell = (y_{\ell,j})_{1 \leq j \leq l}$  and

$$y_{\ell,j} = \begin{cases} 0, & \text{if variable } a_j \text{ does not occur in } \mathcal{A}_\ell, \\ \ell, & \text{if variable } a_j \text{ occurs in } \mathcal{A}_\ell. \end{cases}$$

For any  $1 \leq \ell \leq n$ , it is assumed that  $\mathcal{A}_\ell$  contains three variables  $a_p, a_q, a_r$  with  $1 \leq p < q < r \leq l$ . In this scenario, we observe that there are 7 possible true-false assignments that satisfy the clause  $\mathcal{A}_\ell$ , as  $\mathcal{A}_\ell$  is a disjunction, i.e. there is only 1 possible assignment for which this is not satisfied. For each of these 7 possible true-false assignment to  $(a_p, a_q, a_r)$ , which we label as  $\mathcal{X}_1, \dots, \mathcal{X}_7$ , we define  $D_\ell, D_{\ell,1}, \dots, D_{\ell,7} \subseteq \mathbb{R}^l$  such that

$$D_\ell = \bigcup_{1 \leq i \leq 7} D_{\ell,i}$$

where for any  $1 \leq i \leq 7$ , we define  $D_{\ell,i} = I_{1,\ell,i} \times I_{2,\ell,i} \times \dots \times I_{l,\ell,i}$  in which for any  $1 \leq j \leq l$ , we have

$$I_{j,\ell,i} = \begin{cases} [0, 0.5], & \text{if } a_j \text{ does not occur in } \mathcal{A}_\ell, \\ [\ell + 0.5 - \varepsilon, \ell + 0.5 + \varepsilon], & \text{if } a_j \text{ occurs in } \mathcal{A}_\ell \text{ and } a_j \text{ is true in } \mathcal{X}_i, \\ [\ell - \varepsilon, \ell + \varepsilon], & \text{if } a_j \text{ occurs in } \mathcal{A}_\ell \text{ and } a_j \text{ is false in } \mathcal{X}_i. \end{cases}$$

where  $\varepsilon = \frac{1}{80}$ . We can then define

$$\mathcal{D} = \bigcup_{1 \leq \ell \leq k} D_\ell.$$

We will first observe that all  $(D_{\ell,i})_{1 \leq \ell \leq n, 1 \leq i \leq 7}$  are disjoint, i.e.  $D_{\ell,i}$  is disjoint from  $D_{\ell',i'}$ . To see this, we note that for any  $x, y \in \mathbb{N}$ , the three intervals  $[0, 0.5]$ ,  $[x + 0.5 - \varepsilon, x + 0.5 + \varepsilon]$  and  $[y - \varepsilon, y + \varepsilon]$  are all pairwise disjoint as  $\varepsilon$  is chosen to be small enough. This implies that any point  $\mathbf{y} \in \mathcal{D}$ , coordinate-wise there is at most one interval that contain this point, and thus uniquely determine which interval contain this point.

Now, we will define a probability density function  $f_0$  based on distribution  $\mathcal{D}$ . Here,  $f_0$  is given by

$$f_0(\mathbf{y}) = \begin{cases} \gamma & \text{if } \mathbf{y} \in \mathcal{D} \\ 0 & \text{otherwise} \end{cases}$$

where  $\gamma \in \mathbb{R}$  is defined to be such that  $\gamma = (\int_{\mathcal{D}} 1)^{-1}$ , which can be explicitly calculated as

$$\gamma = (7n(0.5)^{l-3}(2\varepsilon)^3)^{-1} > 0$$

since we have established that all  $(D_{\ell,i})_{1 \leq \ell \leq n, 1 \leq i \leq 7}$  are disjoint.

Our proposed MLE problem is hence as follow:

**Proposed MLE Problem.** Given an unknown parameter  $\boldsymbol{\theta}$  of distribution  $\mathcal{D}$ , which we have defined above, with some appropriate probability density function  $f$  which satisfies  $f(\mathbf{y}) = f_0(\mathbf{y} - \boldsymbol{\theta})$ , where  $f_0$  is defined above. The given  $n$  sample points are  $\mathbf{y}_1, \dots, \mathbf{y}_n \in \mathbb{R}^l$ , we wish to estimate  $\boldsymbol{\theta}$  using maximum likelihood estimation (MLE).

The main theorem is proved by the following claim.

**Claim 3.2.** *There exists  $\hat{\theta} \in \mathbb{R}^l$  such that  $f_0(\mathbf{y}_\ell - \hat{\theta}) > 0$  for all  $1 \leq \ell \leq n$  if and only if there exists a satisfying assignment to the original Boolean formula.*

*Proof.* First, suppose there exists a satisfying assignment to the original Boolean formula. We will prove that there exists  $\hat{\theta} \in \mathbb{R}^l$  such that  $f_0(\mathbf{y}_\ell - \hat{\theta}) > 0$  for all  $1 \leq \ell \leq n$ .

Consider a satisfying assignment  $\mathcal{X}$  of  $(a_1, \dots, a_l)$  to the original Boolean formula and construct  $\bar{\theta} = (\bar{\theta}_j)_{1 \leq j \leq l} \in \mathbb{R}^l$ , where

$$\bar{\theta}_j = \begin{cases} -0.5, & \text{if } a_j \text{ is true in } \mathcal{X}, \\ 0, & \text{if } a_j \text{ is false in } \mathcal{X}. \end{cases}$$

We will now prove that  $f_0(\mathbf{y}_\ell - \bar{\theta}) > 0$  for all  $1 \leq \ell \leq n$ . Fix  $1 \leq \ell \leq k$ , we will prove that  $f_0(\mathbf{y}_\ell - \bar{\theta}) > 0$ , i.e.  $\mathbf{y}_\ell - \bar{\theta} \in \mathcal{D}$ , by our definition of  $f_0$ . By definition of  $\mathbf{y}_\ell = (y_{\ell,j})_{1 \leq j \leq l}$ , we would therefore have

$$y_{\ell,j} - \bar{\theta}_j = \begin{cases} -\bar{\theta}_j, & \text{if variable } a_j \text{ does not occur in } \mathcal{A}_\ell, \\ \ell - \bar{\theta}_j, & \text{if variable } a_j \text{ occurs in } \mathcal{A}_\ell, \end{cases}$$

for any  $1 \leq j \leq l$ . We'll consider two cases: If  $a_p$  does not occur in  $\mathcal{A}_\ell$ , then  $y_{\ell,p} - \bar{\theta}_p = -\bar{\theta}_p \in [0, 0.5] = I_{p,\ell,i}$  for all  $1 \leq i \leq 7$ , corresponding to the 7 possible satisfying assignment for clause  $\mathcal{A}_\ell$ . Otherwise, if  $a_p$  occurs in  $\mathcal{A}_\ell$ , we have

$$y_{\ell,p} - \bar{\theta}_p = \ell - \bar{\theta}_p = \begin{cases} \ell, & \text{if } a_p \text{ is false in } \mathcal{X}, \\ \ell + 0.5, & \text{if } a_p \text{ is true in } \mathcal{X}. \end{cases}$$

However, we see that

$$I_{p,\ell,i} = \begin{cases} [\ell - \varepsilon, \ell + \varepsilon] & \text{if } a_p \text{ is false in } \mathcal{X}_i \\ [\ell + 0.5 - \varepsilon, \ell + 0.5 + \varepsilon] & \text{if } a_p \text{ is true in } \mathcal{X}_i \end{cases}$$

for some fixed  $1 \leq i \leq 7$ . As  $\mathcal{X}$  is a satisfying assignment to the original Boolean formula, then it must be a satisfying assignment to clause  $\mathcal{A}_\ell$  as well, and thus must be equal to  $\mathcal{X}_i$  for some  $1 \leq i \leq 7$  by our assumption. In either of the cases, we obtain that  $\ell - \bar{\theta}_p \in I_{p,\ell,i}$ . This therefore gives us that  $f_0(\mathbf{y}_\ell - \bar{\theta}) > 0$  as  $\mathbf{y}_\ell - \bar{\theta} \in \mathcal{D}$ , as desired.

For the other direction, suppose that there exists  $\theta^* \in \mathbb{R}^l$  such that  $f_0(\mathbf{y}_\ell - \theta^*) > 0$  for all  $1 \leq \ell \leq n$ . Then there exists a satisfying assignment to the original Boolean formula as follows.

Let  $\theta^* \in \mathbb{R}^l$  be such that  $f_0(\mathbf{y}_\ell - \theta^*) > 0$  for all  $1 \leq \ell \leq n$ , or equivalently,  $\mathbf{y}_\ell - \theta^* \in \mathcal{D}$  for all  $1 \leq \ell \leq n$ . Consider the following assignment of  $\mathcal{X}^*$  of  $(a_1, \dots, a_l)$ . We will prove that  $\mathcal{X}^*$  is a satisfying assignment:

$$\mathcal{X}^*(a_j) = \begin{cases} \text{false} & \text{if } \theta_j^* \in [-\varepsilon, \varepsilon] \\ \text{true} & \text{if } \theta_j^* \in [-0.5 - \varepsilon, -\varepsilon] \end{cases}$$

We will first prove that this is well-defined. To do this, we will first show that  $\theta^* \in [-0.5 - \varepsilon, \varepsilon]^l$ .

We recall that for  $1 \leq \ell \leq n$  and  $1 \leq j \leq l$ , we have

$$y_{\ell,j} - \theta_j^* = \begin{cases} -\theta_j^* & \text{if variable } a_j \text{ does not occur in } \mathcal{A}_\ell \\ \ell - \theta_j^* & \text{if variable } a_j \text{ occurs in } \mathcal{A}_\ell \end{cases}.$$

Suppose that variable  $a_j$  occurs in some of  $\mathcal{A}_\ell$ , then as  $\mathbf{y}_\ell - \boldsymbol{\theta}^* \in \mathcal{D}$  for all  $1 \leq \ell \leq n$  implies that for all  $1 \leq \ell \leq l$ , there exists some  $1 \leq i \leq 7$  such that we have

$$I_{j,\ell,i} \ni y_{\ell,j} - \theta_j^* = \begin{cases} -\theta_j^* & \text{if variable } a_j \text{ does not occur in } \mathcal{A}_\ell \\ \ell - \theta_j^* & \text{if variable } a_j \text{ occurs in } \mathcal{A}_\ell \end{cases}$$

However, this gives us several constraints on  $\theta_j^*$  based on whether  $a_j$  occurs in clause  $\mathcal{A}_\ell$ , and the possible assignment of  $a_j$  in that clause. In particular, we obtain  $l$  constraints on  $\theta_j^*$  in which for all  $1 \leq \ell \leq n$ , for some  $1 \leq i \leq 7$ , we have

$$\theta_j^* \in \begin{cases} [-\varepsilon, \varepsilon] & \text{if } a_j \text{ occurs in } \mathcal{A}_i \text{ and } a_j \text{ is assigned to be false in } \mathcal{X}_i \\ [-0.5 - \varepsilon, -0.5 + \varepsilon] & \text{if } a_j \text{ occurs in } \mathcal{A}_i \text{ and } a_j \text{ is assigned to be true in } \mathcal{X}_i \end{cases}.$$

This is enough to show that  $\boldsymbol{\theta}^* \in [-0.5 - \varepsilon, \varepsilon]^l$ .

To prove that  $\mathcal{X}^*$  is a satisfying assignment for the original Boolean formula, we will show that  $\mathcal{X}^*$  is a satisfying assignment for each clause  $\mathcal{A}_1, \dots, \mathcal{A}_n$ . Fix clause  $\mathcal{A}_\ell$  which contains three variables  $a_p, a_q, a_r$ .

We note that by our assignment  $\mathcal{X}^*$ , for some  $1 \leq i \leq 7$ , for  $j \in \{p, q, r\}$ , we have, by definition of  $D_{\ell,i} = I_{1,\ell,i} \times I_{2,\ell,i} \times \dots \times I_{l,\ell,i}$ , that as we have

$$I_{j,\ell,i} = \begin{cases} [l - \varepsilon, l + \varepsilon], & \text{if } a_j \text{ occurs in } \mathcal{A}_\ell \text{ and } a_j \text{ is true in } \mathcal{X}_i, \\ [l - \varepsilon, l + \varepsilon], & \text{if } a_j \text{ occurs in } \mathcal{A}_\ell \text{ and } a_j \text{ is false in } \mathcal{X}_i. \end{cases}$$

We therefore must have

$$\mathcal{X}^*(a_j) = \begin{cases} \text{true} & \text{if } a_j \text{ occurs in } \mathcal{A}_i, \text{ and is assigned to be true in } \mathcal{X}_i \\ \text{false} & \text{if } a_j \text{ occurs in } \mathcal{A}_i, \text{ and is assigned to be false in } \mathcal{X}_i \end{cases}$$

in which case we know that  $\mathcal{X}^*$  induced by our three variables  $\{a_p, a_q, a_r\}$  is  $\mathcal{X}_i$  for some  $1 \leq i \leq 7$ , which by definition, is a satisfying assignment for this clause. This forces  $\mathcal{X}^*$  to be a satisfying assignment for  $\mathcal{A}_\ell$ . As this argument holds for any  $1 \leq \ell \leq n$ , this shows that  $\mathcal{X}^*$  is a satisfying assignment for the original Boolean formula.  $\square$

To finish our proof, we note that by the 3-SAT problem, it is NP-hard to determine whether there exists a satisfying assignment to our original Boolean formula, which by our claim above, implies that it is NP hard to determine whether there exists  $\hat{\boldsymbol{\theta}} \in \mathbb{R}^l$  such that  $f_0(\mathbf{y}_\ell - \hat{\boldsymbol{\theta}}) > 0$  for all  $1 \leq \ell \leq n$ , as desired.  $\square$

We note that for the construction in the preceding NP-hardness proof, the maximum distance  $D$  of any data point or box corner from the origin is  $O(\max(n, l)^{1.5})$ , the minimum width of any box is  $\varepsilon = 1/80$ , and the minimum separation between  $\mathbf{y}_i$ 's is 1. Thus, these quantities are polynomially bounded in terms of the size of the input. Therefore the optimal parameters  $\boldsymbol{\mu}$  and  $\sigma$  for the example constructed in the NP-hardness proof could be approximated in polynomial time in the Wasserstein sense using the algorithm of Section 2.

## 4 Future Work

An interesting direction for future research is to develop an analog of the Expectation-Maximization (EM) algorithm using the methods established here. Traditional EM algorithms rely on maximizing the likelihood function for parameter estimation, but this approach can be computationally hard for general distributions, as computing parameters like  $\mu$  is shown to be NP-hard using MLE. In contrast, incorporating alternative metrics like the Wasserstein distance within the EM framework could provide a more tractable solution, as parameter estimation via minimization under the Wasserstein metric can be achieved in polynomial time. The Wasserstein distance measures similarity between distribution by accounting for the actual geometry between the two distributions through the actual distances between points in the sample space, making it more robust to small sample variations and outliers while preserving the geometric structure of the data.

We also note that our analysis of the hardness result for MLE did not address approximation algorithms, even though we provided a polynomial-time approximation algorithm in the Wasserstein minimization framework. This is because by the standard definition of approximation algorithms, distinguishing between zero and nonzero values is treated equivalently in both exact and approximate contexts. However, alternative definitions of approximation algorithms may exist, under which our hardness result might not hold. Exploring such definitions could offer interesting direction for future research.

Another potential research question lies in identifying the conditions under which parameter estimation from sample points becomes tractable. We have demonstrated that recovering parameters like  $\mu$  and  $\sigma$  is feasible with Wasserstein distance, though this is not the case for maximum likelihood estimation (MLE). Additionally, in some other work, not detailed here, we can show that parameter recovery in the Wasserstein sense becomes NP-hard for mixture distributions with distinct component means: We can extend Dasgupta’s proof of NP-hardness in  $k$ -clustering problems [Das08] to demonstrate that finding two optimal means in a mixture distribution is also NP-hard.

## 5 Acknowledgements

We would like to thank Jason Altschuler for help on the early stages of the work.
