A Note on the Conversion of Nonnegative Integers to the Canonical Signed-digit Representation

R. J. Cintra*

Abstract

This note addresses the signed-digit representation of non-negative integer binary numbers. We review and revisit popular literature methods for canonical signed-digit representation. A method based on string substitution is discussed.

Keywords

Canonical signed-bit representation, non-adjacent form, binary numbers, minimum-adder representation

1 Introduction

Let x be an nonnegative integer. The conventional binary representation of x is the *n*-uple $\mathbf{x} = [x_{n-1} \ x_{n-2} \ \cdots \ x_i \ \cdots \ x_1 \ x_0]$ such that

$$x = \sum_{i=0}^{n-1} 2^{i} \cdot x_{i},$$
 (1)

where *n* is the wordlength; $0 \le i \le n-1$; $x_i \in \{0, 1\}$; and $x_i = 0$, if i < 0 or i > n-1, For instance, considering n = 4, the integer x = 7 is mapped into $\mathbf{x} = \begin{bmatrix} 0 & 1 & 1 & 1 \end{bmatrix}$. A comprehensive discussion on conventional number systems with non-binary base is found in [6, p. 8].

The binary signed-digit number representation of **x** is an (n + 1)-uple $\mathbf{y} = \begin{bmatrix} y_n & y_{n-1} & y_{n-2} & \cdots & y_i & \cdots & y_1 & y_0 \end{bmatrix}$ where $y_i \in \{-1, 0, 1\}$ and

$$x = \sum_{i=0}^{n} 2^i \cdot y_i. \tag{2}$$

For example, the number x = 7 = 8 - 4 + 2 + 1 can be represented as

$$\mathbf{y} = \begin{bmatrix} 0 & 1 & -1 & 1 & 1 \end{bmatrix}. \tag{3}$$

Hereafter, we might represent \mathbf{y} by two binary (n + 1)-uples, $\mathbf{y}^+ = \begin{bmatrix} y_n^+ & y_{n-1}^+ & y_{n-2}^+ & \cdots & y_i^+ & \cdots & y_1^+ & y_0^+ \end{bmatrix}$ and $\mathbf{y}^- = \begin{bmatrix} y_n^- & y_{n-1}^- & y_{n-2}^- & \cdots & y_i^- & \cdots & y_1^- & y_0^- \end{bmatrix}$, indicating the positive and negative coefficients of \mathbf{y} , respectively. Thus, we have:

$$y_i^+ = \begin{cases} 1, & \text{if } y_i = 1, \\ 0, & \text{otherwise,} \end{cases}$$
(4)

$$y_i^- = \begin{cases} 1, & \text{if } y_i = -1, \\ 0, & \text{otherwise,} \end{cases}$$
(5)

$$\mathbf{y} = \mathbf{y}^+ - \mathbf{y}^-. \tag{6}$$

Notice that \mathbf{y}^+ and \mathbf{y}^- are conventional binary numbers; not signed-digit numbers.

The conversion from a given binary number **x** to its signeddigit representation is not unique. For example, the following signed-digit representations correspond to the same number (x = 7):

$$\begin{bmatrix} 0 & 1 & -1 & 1 & 1 \end{bmatrix}, \tag{7}$$

$$\begin{bmatrix} 0 & 1 & 0 & -1 & 1 \end{bmatrix}, \tag{8}$$

$$\begin{bmatrix} 0 & 1 & 0 & 0 & -1 \end{bmatrix}. \tag{9}$$

Because the signed-digit representation is not unique, representations that lead to minimal Hamming weight might be advantageous. For instance, in [6, p. 12], a signed-digit representation is presented which does not necessarily lead to minimal weight. The problem of minimal representation was addressed in [10, p. 244–260]. Reitwiesner showed that such a representation not only exists but it is also unique [10, Sec. 8.3]. Such minimal representation is referred to as the canonical signed-digit representation. A method to convert a generic signed-digit representation to the canonical signed-digit representation is given in [12]. However, in this note, we only address methods that convert numbers from the conventional binary representation to the canonical signed-digit representation.

We adopt the following symbols: $\bar{\ }, \cdot, -, \&, |, \oplus, -, *, and \div$ for logical negation, logical conjunction (and), bitwise logical negation, bitwise logical conjunction (and), bitwise logical disjunction (or), exclusive or (xor) exclusive or bitwise xor, arithmetic subtraction, arithmetic multiplication, and integer division operations, respectively. The symbol + denotes both logical disjunction (or) and arithmetic addition, being the meaning clear from the context.

This note is structured as follows. Section 2 reviews popular methods in the literature. In Section 3, we revisit some of the discussed literature methods, offering comments and remarks. Section 4 describes an encoding method based on string substitution. Section 5 discusses the performance results. The note is concluded in Section 6.

2 Literature Review

In this section, we review some methods for canonical signeddigit conversion.

2.1 Reitwiesner's Method

In [10, p. 252], Reitwiesner proposed a conversion from binary to the minimal signed-digit representation; the method is given in Algorithm 1. The main computational bottleneck of this algorithm resides in the evaluation of recurrence that generates the sequence g_i , i = 0, 1, ..., n.

The arithmetic expression $1-2 * x_{i+1}$ is present in Reitwiesner's work [10, Eq. 8.6.9 ξ , p. 252] and it is also adopted in [3, p. 393]. It might be efficiently computed by means of the following identity: $1-2 * x_{i+1} = \bar{x}_{i+1} - x_{i+1}$.

2.2 Garner Method

In [4, p. 164], Garner showed a table with the rules for the canonical signed-digit code. Such table and rules are reproduced in [6,9,11]; and we reproduce it yet again in Table 1. The coefficients c_i , i = 0, 1, ..., n, represent the carry-out sequence effected by the arithmetic addition of **x** and $\mathbf{x} \div 2$. Appendix A offers a

1	1	1	1	0	0

brief review on the carry-out computation. Algorithm 13 shows how to obtain such sequence from the output of the full-adder operation.

From Garner's work [4], it is not clear whether the discussed coding rules are originally due to him. Reitwiesner's work [10] presents three tables relating the bit values of x_{i+i} and x_i to several other auxiliary sequences and ultimately to the encoded signed-digit coefficients. However, no clear-cut table as shown in [4, p. 164] was found in [10]. Despite the fact that an explicit algorithm for the rules in Table 1 was not given in [4]—in the absence of better sources—we refer to the algorithms immediately derived from these rules as the Garner algorithms.

The conversion rules (Table 1) were algorithmically described in at least two ways. One approach expresses the rules in terms of arithmetic operations as shown in [3, Eq. 5–6] and [6, p. 150]. This method is shown in Algorithm 2.

Another approach consists of inspecting the truth table in Table 1 to obtain the logic expression for y_i^+ and y_i^- in terms of c_i , x_{i+1} , and x_i . By doing so, we have that

$$y_{i}^{+} = \bar{c}_{i} \cdot \bar{x}_{i+1} \cdot x_{i} + c_{i} \cdot \bar{x}_{i+1} \cdot x_{i}$$
(10)

$$=\bar{x}_{i+1}\cdot(c_i\oplus x_i),\tag{11}$$

$$y_i^- = \bar{c}_i \cdot x_{i+1} \cdot x_i + c_i \cdot x_{i+1} \cdot \bar{x}_i \tag{12}$$

$$=x_{i+1}\cdot(c_i\oplus x_i). \tag{13}$$

Such logic-based formalism coincides with the description shown in [11, Eq. 8–10], where [6,9] are given as references. However, Garner's work [4] antedates both [9] and [6]. Peled [9] points to [4,10] as primary sources; whereas Hwang [6] does not provide a reference.

2.3 NAF Algorithm

Referring to the canonical signed-digit representation as nonadjacent form (NAF), Hankerson *et al.* present an algorithm for computing the NAF of a positive integer in [5, p. 98]. Algorithm 4 shows the pseudocode. **Algorithm 2** Garner canonical signed-digit conversion algorithm as described in [3, Eq. 5–6] and [6, p. 150]

```
1: procedure GARNERARITH(x)

2: \mathbf{c} \leftarrow \text{GETCARRY}(\mathbf{x}, \mathbf{x} \div 2)

3: i \leftarrow 0

4: while i \leq n do

5: y_i \leftarrow x_i + c_i - 2 * c_{i+1} \triangleright Arithmetic operations

6: i \leftarrow i + 1

7: return y
```

Algorithm 3 Rule-based canonical signed-digit conversion algorithm

1:	procedure GARNERLOGIC(x)
2:	$\mathbf{c} \leftarrow \text{GetCarry}(\mathbf{x}, \mathbf{x} \div 2)$
3:	$i \leftarrow 0$
4:	while $i \leq n$ do
5:	$d_i \leftarrow c_i \oplus x_i$
6:	$y_i^+ \leftarrow \bar{x}_{i+1} \cdot d_i$
7:	$y_i^- \leftarrow x_{i+1} \cdot d_i$
8:	$y_i \leftarrow y_i^+ - y_i^-$
9:	$i \leftarrow i + 1$
10:	return y

2.4 bin2naf Algorithm

In [2, p. 61], the canonical signed-digit representation is referred to as sparse signed binary representation or—as in [5]—as NAF. An algorithm to convert the conventional binary representation to the nonadjacent form is also furnished, which is shown in Algorithm 5.

2.5 Ruiz-Granda Algorithm

Ruiz and Granda introduced in [11] a method for canonical signed-digit coding. The method is based on two auxiliary recursive sequences. Algorithms 6 and 7 describe the procedure.

3 Revisited Methods

In this section, we revisit some literature methods, aiming at deriving remarks and relations among them.

3.1 Modified Reitwiesner's Method

The recursion required by Reitwiesner's method can be obtained by means of the carry-out recursion. It can be shown that the sequence g_i , i = 0, 1, ..., n, (Algorithm 1) satisfies the following relation:

$$g_i = c_{i+1} \oplus x_i, \tag{14}$$

Algo	orithm 4 NAF algorithm

3:	$\mathbf{t} \leftarrow \mathbf{x} + \mathbf{h}$
4:	$\mathbf{d} \leftarrow \mathbf{h} \oplus \mathbf{t}$
5:	$\mathbf{y}^+ \leftarrow \mathbf{t} \& \mathbf{d}$
6:	$\mathbf{y}^- \leftarrow \mathbf{h} \& \mathbf{d}$
7:	$\mathbf{y} \leftarrow \mathbf{y}^+ - \mathbf{y}^-$

return y 8:

Algorithm 6 Ruiz-Granda h and k sequences

1: procedure GETHK(x) 2: $h_{-1} \leftarrow 0$ $k_{-1} \leftarrow 0$ 3: $i \leftarrow 0$ 4: while $i \leq n$ do 5: if *i* is even **then** 6: 7: $h_i \leftarrow x_i + h_{i-1}$ 8: $k_i \leftarrow x_i \cdot k_{i-1}$ 9: else 10: $h_i \leftarrow x_i \cdot h_{i-1}$ 11: $k_i \leftarrow x_i + k_{i-1}$ $i \leftarrow i + 1$ 12: return h, k 13:

where c_i , i = 0, 1, ..., n, is the particular carry-out sequence generated by the addition $\mathbf{x} + 2 * \mathbf{x}$. By applying the above considerations to Algorithm 1, we obtain Algorithm 8.

3.2 bin2naf Revisited

Algorithm 5 is very similar to Algorithm 3. To show this, let us recast Algorithm 3 in terms of tuple operations, instead of individual coefficient operations. The result is Algorithm 9.

First, notice that the tuple **d** in Algorithm 5 is equal to the tuple **d** from Algorithm 9, as shown below:

$$\mathbf{d} = \mathbf{h} \oplus \mathbf{t} \tag{15}$$

$$= \mathbf{h} \oplus (\mathbf{c} \oplus \mathbf{x} \oplus \mathbf{h}) \tag{16}$$

$$= \mathbf{h} \oplus \mathbf{h} \oplus \mathbf{c} \oplus \mathbf{x} \tag{17}$$

$$= \mathbf{c} \oplus \mathbf{x}$$
(18)
= **d**. (19)

$$=\mathbf{d}.$$
 (19)

Now let us shown that both y^+ are also identical. Notice that $\mathbf{t} = \mathbf{c} \oplus \mathbf{x} \oplus \mathbf{h} = \mathbf{d} \oplus \mathbf{h}$ (see (19)). From Algorithm 5, we have that:

$$\mathbf{y}^{+} = \mathbf{t} \,\& \, \mathbf{d} \tag{20}$$

$$= (\mathbf{d} \oplus \mathbf{h}) \,\& \, \mathbf{d} \tag{21}$$

$$= \left((\mathbf{d} \& \sim \mathbf{h}) | (\sim \mathbf{d} \& \mathbf{h}) \right) \& \mathbf{d}$$

$$= \sim \mathbf{h} \, \& \, \mathbf{d} \tag{23}$$

$$=\mathbf{y}^{+},$$
(24)

which is the expression for y^+ in Algorithm 9. As for y^- , the logical expressions are already plainly identical in both algorithms.

3.3 Garner Algorithm Revisited

Algorithm 9 can be further simplified. First, from (15), recall that $\mathbf{d} = \mathbf{h} \oplus \mathbf{t}$. From Algorithm 5, we have that:

$$\mathbf{y}^+ = \mathbf{t} \,\& \, \mathbf{d} \tag{25}$$

$$= \mathbf{t} \,\& (\mathbf{h} \oplus \mathbf{t}) \tag{26}$$

$$= \sim \mathbf{h} \, \& \, \mathbf{t}. \tag{27}$$

Algorithm 7 Ruiz-Granda Algorithm

1:	procedure RUIZGRANDA(x)
2:	$\mathbf{h}, \mathbf{k} \leftarrow \text{GETHK}(\mathbf{x})$
3:	$i \leftarrow 0$
4:	while $i \leq n$ do
5:	if <i>i</i> is even then
6:	$d_i \leftarrow h_i \cdot \bar{k}_i$
7:	else
8:	$d_i \leftarrow \bar{h}_i \cdot k_i$
9:	$y_i^+ \leftarrow \bar{x}_{i+1} \cdot d_i$
10:	$y_i^- \leftarrow x_{i+1} \cdot d_i$
11:	$y_i \leftarrow y_i^+ - y_i^-$
12:	$i \leftarrow i + 1$
13:	return y

Algorithm 8 Modified Reitwiesner canonical signed-digit conversion algorithm

1:	$procedure \; \texttt{REITWIESNERMODIFIED}(x)$
2:	$\mathbf{c} \leftarrow \text{GETCARRY}(\mathbf{x}, 2 * \mathbf{x})$
3:	$i \leftarrow 0$
4:	while $i \leq n$ do
5:	$g_i \leftarrow c_{i+1} \oplus x_i$
6:	$y_i^+ \leftarrow \bar{x}_{i+1} \cdot g_i$
7:	$y_i^- \leftarrow x_{i+1} \cdot g_i$
8:	$y_i \leftarrow y_i^+ - y_i^-$
9:	$i \leftarrow i + 1$
10:	return y

Similarly, from Algorithm 9, the following is true:

$$\mathbf{y}^{+} = \sim \mathbf{h} \& \mathbf{d}$$
(28)
= $\sim \mathbf{h} \& (\mathbf{h} \oplus \mathbf{t})$ (29)

$$= \sim \mathbf{h} \, \& \, \mathbf{t}. \tag{30}$$

And finally, from Algorithms 5 and 9, we obtain:

$$\mathbf{y}^{-} = \mathbf{h} \,\& \, \mathbf{d} \tag{31}$$

$$=\mathbf{h}\,\&\,(\mathbf{h}\oplus\mathbf{t})\tag{32}$$

$$=\mathbf{h}\,\&\,\sim\mathbf{t}.\tag{33}$$

By applying the above results back into Algorithm 9, we obtain Algorithm 10.

4 String Substitution Method

In this section, we describe a direct method based on string substitution.

4.1 Pattern Finding

Following [8, p. 611, Answer 34] and [11, Fig. 1], a moment's reflection shows that the canonical signed-digit representation can be achieved by direct pattern substitution. Let us denote the pattern 00w11 as a 'w-block', where w is either empty or the longest

Algo	Algorithm 9 Reformatted Algorithm 3

3:	$\mathbf{c} \leftarrow \text{GetCarry}(\mathbf{x}, \mathbf{h})$		
4:	$\mathbf{d} \leftarrow \mathbf{c} \oplus \mathbf{x}$		
5:	$\mathbf{y}^+ \leftarrow \sim \mathbf{h} \& \mathbf{d}$		
6:	$\mathbf{y}^- \leftarrow \mathbf{h} \& \mathbf{d}$		
7:	$\mathbf{y} \leftarrow \mathbf{y}^+ - \mathbf{y}^-$		
8:	return y		

(22)

Algorithm 10 Revisited Garner canonical signed-digit conversion algorithm

1: p	1: procedure GARNERREVISITED(x)		
2:	$\mathbf{h} \leftarrow \mathbf{x} \div 2$		
3:	$\mathbf{t} \leftarrow \mathbf{x} + \mathbf{h}$		
4:	$\mathbf{y}^+ \leftarrow \sim \mathbf{h} \& \mathbf{t}$		
5:	$\mathbf{y}^- \leftarrow \mathbf{h} \& \sim \mathbf{t}$		
6:	$\mathbf{y} \leftarrow \mathbf{y}^+ - \mathbf{y}^-$		
7:	return y		

sequence of zeros and ones such that (i) it has a leading 1 at the leftmost position and (ii) no consecutive zeros are present. The canonical signed-digit representation consists of the following substitution:

$$\dots 00\mathbf{w}11 \dots \to \dots 01[-\overline{\mathbf{w}}]0\overline{1} \dots, \qquad (34)$$

where $\overline{1} \triangleq -1$; $[-\overline{\mathbf{w}}]$ operates over the digits of \mathbf{w} according to: $0 \rightarrow \overline{1}$ and $1 \rightarrow 0$; and $[-\overline{\mathbf{w}}] = \emptyset$, if $\mathbf{w} = \emptyset$. All other patterns that do not match the 'w-block' format are simply copied to the output without any change. For example,

$$0000 00111 000 \to 0000 0100\bar{1} 000, \tag{35}$$

$$001010111 000 \to 010\bar{1}0\bar{1}00\bar{1} 000, \tag{36}$$

$$0010 \ 00111 \ 001 \rightarrow 0010 \ 0100\overline{1} \ 001, \tag{37}$$

$$0010 00111011 \to 0010 01000\bar{1}0\bar{1}, \qquad (38)$$

$$0000 0011 0000 \rightarrow 0000 0101 0000.$$
(39)

The above last example illustrates the case in which ${f w}$ is empty.

One way of mathematically describing the above pattern substitution consists of considering (i) a two-bit sliding window moving from right to left that scans two consecutive digits x_{i+1} and x_i and (ii) an flag bit f_i ($f_0 = 0$) to indicate whether the sliding window is over a 'w-block' or not. Two consecutive ones mark the start of the 'w-block' pattern ($f_{i+1} = 1$); whereas two consecutive zeros mark its end ($f_{i+1} = 0$). For each *i*, the resulting canonical signed-digit number is y_i .

Algorithm 11 directly realizes the discussed string-based approach. Algorithm 12 is an alternative version of Algorithm 11.

1	0	1	ī	0	1	1
1	1	1	0	0	0	1

4.2 Proof

The pattern substitution rules imply the finite-state machine shown in Figure 1, which translates into Table 2. By inspecting this truth table (Table 2), we can obtain the logical expressions for y_i^+ , y_i^- , and f_i , as follows:

$$y_{i}^{+} = \bar{x}_{i+1} \cdot x_{i} \cdot \bar{f}_{i} + \bar{x}_{i+1} \cdot \bar{x}_{i} \cdot f_{i}$$
(40)

 $=\bar{x}_{i+1}\cdot(x_i\oplus f_i),\tag{41}$

$$y_i^- = x_{i+1} \cdot x_i \cdot \bar{f}_i + x_{i+1} \cdot \bar{x}_i \cdot f_i \tag{42}$$

$$=x_{i+1}\cdot(x_i\oplus f_i),\tag{43}$$

$$f_{i+1} = x_{i+1} \cdot x_i \cdot f_i + \bar{x}_{i+1} \cdot x_i \cdot f_i + x_{i+1} \cdot x_i \cdot f_i + x_{i+1} \cdot \bar{x}_i \cdot f_i \quad (44)$$

$$= x_{i+1} \cdot x_i + \bar{x}_{i+1} \cdot x_i \cdot f_i + x_{i+1} \cdot \bar{x}_i \cdot f_i$$
(45)

$$=x_{i+1}\cdot x_i + f_i\cdot \left(\bar{x}_{i+1}\cdot x_i + x_{i+1}\cdot \bar{x}_i\right) \tag{46}$$

$$=x_{i+1}\cdot x_i+f_i\cdot (x_{i+1}\oplus x_i). \tag{47}$$

One can recognize that the above expressions for y_i^+ and y_i^- are identical to the expressions (10)–(13). Moreover, the flag bit f_i and the carry-out sequence c_i from a full adder have the same logical expression. Therefore, the discussed string substitution algorithm is mathematically equivalent to Algorithms 5, 9, and 10.

5 Performance Evaluation and Discussion

5.1 Coding

The algorithms listed in the previous sections were implemented in Julia language [13]. As much as we could, the sought codes were based on bitwise operations for higher performance. The

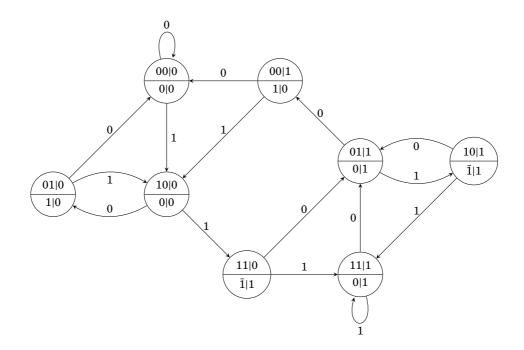

Figure 1: State diagram for the conversion to the canonical signed-digit representation. State $x_{i+1}x_i|f_i$ and output $y_i|f_{i+1}$.

programs usually follow the direct specification from their respective pseudocodes. The resulting codes were checked against all 32-bit inputs. The method BIN2NAF was adopted as the reference standard.

5.2 Assessment

Table 3 displays the benchmark statistical summary as evaluated by the Julia BenchmarkTools [1]. Uniform random integers in the interval $[0,2^{32}-1]$ were submitted as input to each algorithm. Results were estimated according to 1000 samples of 1000 evaluations each. Multithreading was not employed. The machine used for the performance measurements possessed a 64bit processor (Intel Core i5-10400F CPU) running at an average clock of 4.1 GHz.

5.3 Discussion

The Julia implementation for algorithms GARNER (Algorithm 9), BIN2NAF (Algorithm 5), and GARNERREVISITED (Algorithm 10) showed essentially the same performance. The particular order in which these three top algorithms appear in Table 3 should not be taken as definite. The estimated performance measurements presented small random variations (e.g., changes in the order of 10^{-3} ns) in the simulation; thus keeping the figures almost unchanged. The absence of loop and branching structures combined with low-level bitwise operations ensured their relatively higher performance. As shown in Section 3, these three methods have very similar structures.

Algorithms REITWIESNER (Algorithm 1) and RUIZGRANDA (Algorithm 7) are based on the evaluation of specific recursive sequences. The former requires the sequence \mathbf{g} ; whereas the latter needs sequences \mathbf{h} and \mathbf{k} . The sequence \mathbf{g} could be connected to the carry-out sequence by means of (14). Therefore, \mathbf{g} could be efficiently computed. This resulted in the REITWIESNERMODI-FIED algorithm (Algorithm 8)

On the other hand, we could not find an efficient way to solve the recursions required by the RUIZGRANDA algorithm. Thus we resorted to the direct approach based on loop structures (Algorithm 6). Unfortunately, this approach effected bottlenecks and resulted in comparatively increased execution times (Min.: 56.205 ns, Max.: 118.353 ns, Median: 56.513 ns, Mean: 57.535 ns, and Standard deviation: 4.433 ns). Such measurements should be taken with care. The relatively higher execution times are primarily due to our failure to derive an efficient implementation for the computation of the required recursive sequences rather than to any intrinsic inefficiency in the algorithm itself. As a consequence, these results were not included in Table 3, lest it would be an unfair comparison or a misleading information.

The string substitution method STRING_0 (Algorithm 11) is comparable to the method proposed in [7, Algorithm 5.2], which relies on a pattern search algorithm (FindPattern(), [7, Algorithm 5.1]). We could not clearly identify from [7] how their pattern search algorithm operates, which prevented our reproducing their algorithm. Additionally, the substitution scanner provided in [7] requires a scanning window encompassing x_{i+1} , x_i , x_{i-1} , and x_{i-2} ; whereas the discussed scanner reads x_{i+1} and x_i only.

The alternative algorithm STRING_1 (Algorithm 12) could perform better than algorithm NAF (Algorithm 4). However, it could not outcompete the top performing methods—yet again a statement on the efficiency of the full-adder operation in current processors.

6 Conclusions

To the best of our knowledge, the Garner Method as shown in the revised form GARNERREVISITED (Algorithm 10) is not listed in the literature. We clarified the equivalence of methods GARNERREVISITED (Algorithm 10), BIN2NAF (Algorithm 5), and GARNER (Algorithm 9). We emphasized the role of the carry-out sequence, derived from a full adder, as a means to improve the performance of REITWIESNER algorithm, resulting in REITWIESNERMODIFIED algorithm (Algorithm 8).

As far as we know, the string substitution algorithms as shown in STRING_0 (Algorithm 11) and STRING_1 (Algorithm 12) are not archived in the literature, albeit comparable methods are available.

For future work, we aim at providing an efficient way for computing the sequences \mathbf{h} and \mathbf{k} required by Algorithm 7. In conclusion, due to its simplicity and high performance, the revisited Garner algorithm (GARNERREVISITED, Algorithm 10) appears as the recommended algorithm.

Table 3: Performance comparison of the discussed methods: Statistics of execution time (measured in ns). Algorithms sorted by mean measurements. See text for implementation details.

Algorithm	Mininum	Maximum	Median	Mean	Std dev
GARNERREVISITED	2.119	17.656	2.135	2.146	0.327
GARNER [4]	2.121	17.478	2.136	2.147	0.324
BIN2NAF [2]	2.120	21.541	2.132	2.149	0.352
REITWIESNERMODIFIED	2.409	26.316	2.423	2.440	0.454
STRING_1	5.981	44.410	14.816	14.743	2.431
NAF [5]	16.413	90.181	25.263	25.742	4.181
STRING_0	24.573	107.925	31.709	31.675	3.045
REITWIESNER [10]	51.864	118.583	52.031	52.989	4.151

A Carry-out Sequence

The carry-out sequence c is generated by the binary full-adder operating over an augend a and an addend b, being the resulting

sum the sequence **s**. For example, considering n = 3, we have the following well-known structure:

	c_4	c_3	c_2	c_1	c_0
		a_3	a_2	a_1	a_0
+		b_3	b_2	b_1	b_0
	s_4	s_3	s_2	s_1	s_0

The coefficients of ${\bf c}$ are given by the following recurrence:

$$c_{i+1} = a_i \cdot b_i + c_i \cdot (a_i \oplus b_i)$$
(48)
= $a_i \cdot b_i + c_i \cdot (a_i + b_i), \quad i = 1, 2, ..., n,$ (49)

where $c_0 = 0$. The sum coefficients are given by:

$$s_i = c_i \oplus a_i \oplus b_i, \quad i = 1, 2, \dots, n.$$

$$(50)$$

The full adder offers an efficient way of generating **c**. Its truth table is given by:

c_i	a_i	b_i	s_i
0	0	0	0
0	0	1	1
0	1	0	1
0	1	1	0
1	0	0	1
1	0	1	0
1	1	0	0
1	1	1	1

Therefore, taking a_i , b_i , and s_i as input Boolean variables, we have that

$$c_i = a_i \oplus b_i \oplus s_i. \tag{51}$$

Algorithm 13 describes the procedure.

Algorithm 13 Algorithm for solving the carry-out recursion				
1: 1	procedure GETCAR	RY(a , b)		
2:	$\mathbf{s} \leftarrow \mathbf{a} + \mathbf{b}$	▷ Addition efficiently computed		
3:	$\mathbf{c} \leftarrow \mathbf{a} \oplus \mathbf{b} \oplus \mathbf{s}$			
4:	return c
