**Abstract**—Low-light image enhancement (LLE) aims to improve the visual quality of images captured in poorly lit conditions, which often suffer from low brightness, low contrast, noise, and color distortions. These issues hinder the performance of computer vision tasks such as object detection, facial recognition, and autonomous driving. Traditional enhancement techniques, such as multi-scale fusion and histogram equalization, fail to preserve fine details and often struggle with maintaining the natural appearance of enhanced images under complex lighting conditions. Although the Retinex theory provides a foundation for image decomposition, it often amplifies noise, leading to suboptimal image quality. In this paper, we propose the Dual Light Enhance Network (DLEN), a novel architecture that incorporates two distinct attention mechanisms, considering both spatial and frequency domains. Our model introduces a learnable wavelet transform module in the illumination estimation phase, preserving high- and low-frequency components to enhance edge and texture details. Additionally, we design a dual-branch structure that leverages the power of the Transformer architecture to enhance both the illumination and structural components of the image. Through extensive experiments, our model outperforms state-of-the-art methods on standard benchmarks. Code is available here: <https://github.com/LaLaLoXX/DLEN>

## I. INTRODUCTION

Low-light image enhancement (LLE) constitutes a pivotal area of study within the broader fields of computer vision and image processing. This task is fundamentally aimed at improving the visual quality and perceptual clarity of images captured in suboptimal lighting conditions, thereby enhancing their interpretability and functional utility. Images acquired under low-light environments often suffer from insufficient brightness, low contrast, increased noise, and pronounced color distortions. These limitations can critically undermine performance in a variety of downstream computer vision applications, such as object detection, facial recognition, and autonomous driving systems. As a result, LLE has become an essential area of research in computer vision and image processing.

Traditional image enhancement techniques, such as multi-scale fusion [43] [44], homomorphic filtering [45] [46], and histogram equalization [1] [5], have been widely explored. However, these methods often rely on relatively simple algorithms, and they suffer from significant limitations, particularly in preserving fine details. They frequently fail to maintain the natural appearance of enhanced images, especially under

complex and varying lighting conditions. The classical Retinex theory [6] introduced a novel framework for image decomposition, suggesting that a color image can be separated into two components: illumination and reflection. Although this approach often amplifies noise and results in suboptimal image quality, it has provided a foundational basis for addressing modern challenges in low-light image enhancement.

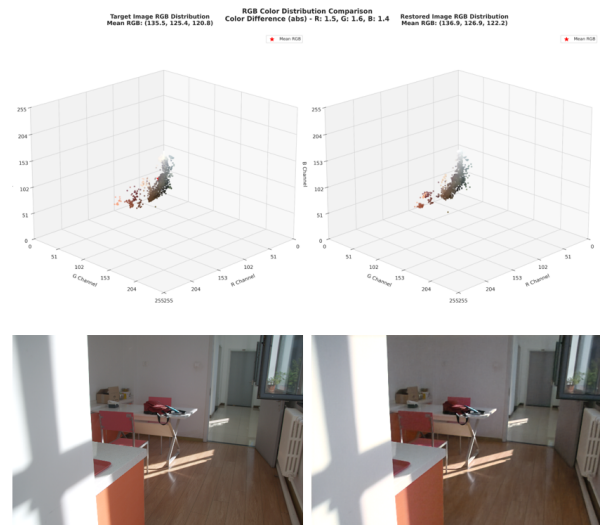

Fig. 1. The target image (left) and the enhanced result (right) produced by our method. Our approach effectively enhances the image in color space.

Recent advancements in neural networks, particularly convolutional neural networks (CNNs), transformer models, and mamba [48], have set new benchmarks in low-light image enhancement. CNNs [7] [8] are effective and adaptable, leveraging local feature extraction and pooling. However, they are limited by their reliance on local receptive fields, which restricts their ability to capture global illumination. Additionally, their dependence on large labeled datasets poses challenges for generalizing across diverse low-light scenarios. In contrast, transformer models [9] [11], with their multi-head self-attention mechanism, excel at capturing global illumination and modeling long-range pixel relationships. Incorporating illumination-aware modules has further improved their ability to produce natural enhancement results. However, transformers may introduce artifacts due to over-enhancement and are highly dependent on domain-specific data, making it difficult

Fig. 2. Visualized results on a benchmark dataset. Each image shows the input image, the output produced by our method, and the corresponding target image.

to train a universal model for a wide variety of low-light conditions, such as nighttime, indoor, or foggy scenes.

In this paper, we propose the **Dual Light Enhance Network (DLEN)**, a novel architecture for low-light image enhancement that incorporates two distinct attention mechanisms, simultaneously considering both the spatial and frequency domains. Our network structure builds upon the work in [9] and consists of two main components: the illumination estimation module and the restorer module. Unlike [9], we introduce a learnable wavelet transform module in the illumination estimation phase. This module effectively learns and preserves both high-frequency and low-frequency components, significantly enhancing edge and texture details under extremely low-light conditions. Furthermore, we design a novel dual-branch restorer structure that leverages the expressive power of the Transformer architecture. The first branch (MIAB) enhances different regions of the image based on illumination guidance, while the second branch (SEAB) focuses on enhancing and repairing the structural information of the image, with both branches being fused for the final output.

Through extensive experiments, we present both quantitative and qualitative results that highlight the superiority of our model on standard benchmarks. As demonstrated in Tab. I, our approach outperforms state-of-the-art deep learning methods on the LOL dataset [13] [14].

*Our contributions are summarized as follows:*

- 1) We introduce a learnable wavelet transform module that captures and restores high-frequency details during the enhancement process, enabling our model to perform enhancement in both the spatial and frequency domains.
- 2) We design a dual-branch enhancement structure that effectively leverages the expressive power of the Transformer architecture. This structure facilitates spatial interactions and learning across various regions under different conditions, significantly improving both the illumination and structural components of the image.

- 3) Extensive qualitative and quantitative experiments demonstrate that our model outperforms current mainstream baseline methods.

## II. RELATED WORK

### A. Low-Light Image Enhancement

**Direct Enhancement Methods:** Traditional methods, such as Histogram Equalization [2] [3] [4] and Gamma Correction [15] [16] [17], improve contrast and brightness by adjusting the image’s gray-level distribution or by applying nonlinear functions to modify pixel values. These methods are simple and effective, but they may lead to over-enhancement or loss of details, especially in high dynamic range (HDR) scenes. Moreover, these methods are sensitive to parameter selection, which can introduce color distortion issues.

**Traditional Enhancement Methods:** Traditional methods decompose an image into illumination and reflection components [6], simulating human visual perception of brightness and color to significantly enhance the representation of contrast and detail. For example, the model, proposed by [27], has shown excellent performance in applications such as underwater imaging, remote sensing, and foggy or dusty environments. However, these methods [18] [19] [20] often struggle to handle noise effectively and exhibit poor performance in terms of detail preservation.

**Deep Learning Methods:** Deep learning-based methods for low-light image enhancement have led the field since [24]. Following the Retinex theory [6], CNN-based approaches [25], [29], [31] became widely adopted, with [21], [29] combining Retinex decomposition with deep learning. However, these methods struggled with long-range dependencies. [?] and [9] addressed this by introducing transformer architectures, though these models face computational challenges with long sequences.

## B. Low Level Vision Transformer

The Transformer model, originally proposed by [10], is a neural network architecture designed for natural language processing. It captures global dependencies by computing pairwise interactions between input elements through a self-attention mechanism [33] [34]. In recent years, Transformers have been applied to low-light image enhancement [11] [12], addressing the limitations of CNNs in modeling long-range dependencies. For instance, [30] introduced the SNR-Net model, which integrates global Transformer layers into a U-shaped CNN to enhance structural understanding. [9] combines Retinex theory with a single-stage Transformer framework, achieving better noise reduction and structural consistency. However, the high computational cost and low interpretability of Transformer models remain significant obstacles to their application in real-time scenarios.

## C. Wavelet Transforms Application

Wavelet transforms have become a critical tool in addressing low-level vision tasks by leveraging frequency-domain analysis. In image denoising, wavelet-based methods [39] [40] [41] effectively separate high-frequency noise from low-frequency signals, enhancing restoration quality. Similarly, wavelet techniques have been applied to image super-resolution [47], focusing on high-frequency components to recover fine details. In image deblurring, wavelet transforms enable efficient modeling of motion blur trajectories, outperforming traditional spatial-domain methods. Recent advancements include [42], a multiscale motion-deblurring network that integrates a learnable discrete wavelet transform module. By capturing directional continuity and frequency features, [42] simplifies coarse-to-fine schemes and achieves state-of-the-art performance across multiple datasets.

## III. METHODS

As shown in Figure.3, our architecture comprises two primary components: the Light Component Predictor (LCP) and the Dual-Branch Restorer (DBR). Drawing inspiration from the Retinex theory [6], the LCP consists of multiple convolutional layers, followed by a learnable wavelet transform network designed to capture various illumination effects. The DBR, on the other hand, is built upon two essential units: the Multi-Illumination Attention Block (MIAB) and the Structure Enhancement Attention Block (SEAB), as depicted in Figure.3(b). These components work in tandem to improve restoration quality under varying lighting conditions.

### A. Overall Pipeline

According to the Retinex theory, a low-light image  $\mathbf{I} \in \mathbb{R}^{H \times W \times 3}$  can be decomposed into a reflection image  $\mathbf{R} \in \mathbb{R}^{H \times W \times 3}$  and an illumination image  $\mathbf{L} \in \mathbb{R}^{H \times W}$ , expressed as:

$$\mathbf{I} = \mathbf{R} \odot \mathbf{L}, \quad (1)$$

where  $\odot$  denotes element-wise multiplication. The reflection image  $\mathbf{R}$  captures the intrinsic properties of the object, while

the illumination image  $\mathbf{L}$  represents the lighting conditions. However, this formulation fails to account for the noise and artifacts introduced by uneven light distribution or dark scenes in low-light conditions. Such artifacts are further exacerbated during image enhancement. To address these issues, we introduce perturbation terms for the illumination and reflection components, denoted as  $\tilde{\mathbf{L}}$  and  $\tilde{\mathbf{R}}$ , respectively, in the original equation:

$$\mathbf{I} = (\mathbf{R} + \tilde{\mathbf{R}}) \circ (\mathbf{L} + \tilde{\mathbf{L}}), \quad (2)$$

which expands to:

$$\mathbf{I} = \mathbf{R} \circ \mathbf{L} + \mathbf{R} \circ \tilde{\mathbf{L}} + \tilde{\mathbf{R}} \circ \mathbf{L} + \tilde{\mathbf{R}} \circ \tilde{\mathbf{L}}. \quad (3)$$

After simplification, the illuminated image  $I_{lu}$  can be expressed as:

$$I_{lu} = \mathbf{I} \circ \tilde{\mathbf{L}} = \mathbf{R} + \mathbf{C}, \quad (4)$$

where  $\tilde{\mathbf{L}}$  represents the illumination mapping obtained through convolution for feature extraction, and  $\mathbf{C} \in \mathbb{R}^{H \times W \times 3}$  denotes the losses associated with the perturbations. Thus, our Dual Light Enhancement Network can be described as:

$$(I_{lu}, F_{lu}) = \text{LCP}(I, L_p), \quad (5)$$

$$\text{DBR}(I_{lu}, F_{lu}) = \text{ILB}(I_{lu}, F_{lu}) + \text{SEB}(I_{lu}), \quad (6)$$

$$\text{DLEN} = I_{lu} + \text{DBR}(I_{lu}, F_{lu}), \quad (7)$$

where LCP refers to the Light Component Predictor, and DBR represents the Dual-Branch Restorer. The ILB and SEB are the two branches of the DBR, representing the Illumination Learning Branch and the Structure Enhancement Branch, respectively. The LCP takes the low-light image  $I$  and the illumination prior  $L_p \in \mathbb{R}^{H \times W}$  as input, producing the illuminated image  $I_{lu} \in \mathbb{R}^{H \times W \times 3}$  and the feature map  $F_{lu} \in \mathbb{R}^{H \times W \times C}$ . The illumination prior  $L_p$  is computed by taking the average value of each channel in the image, providing a measure of the overall brightness or illumination level. Consequently,  $L_p$  functions as an illumination prior, guiding the extraction of lighting information for the image. This version refines the wording while preserving the technical accuracy. Let me know if you'd like any further changes! The outputs of LCP are then fed into the Dual-Branch Restorer (DBR) to mitigate the quality loss exacerbated during illumination enhancement. Before  $F_{lu}$  enters the Illumination Learning Branch (ILB), it first passes through the Learnable Wavelet Network (LWN), which aims to further restore the quality loss and enhance the feature learning after the wavelet transformation. The two results from LCP are processed separately by the DBR, resulting in the final restored image, which is represented as  $\text{DLEN} \in \mathbb{R}^{H \times W \times 3}$ .

### B. Dual-Branch Restorer

Figure.3 illustrates the structure of our Dual-Branch Restorer, which consists of two attention-based branches, each with slightly different architectural designs. In this section, we provide a detailed description of these two branches. The restorer enables spatial interactions and learning across different locations under two conditions, effectively enhancing both the illumination and structural components of the image.

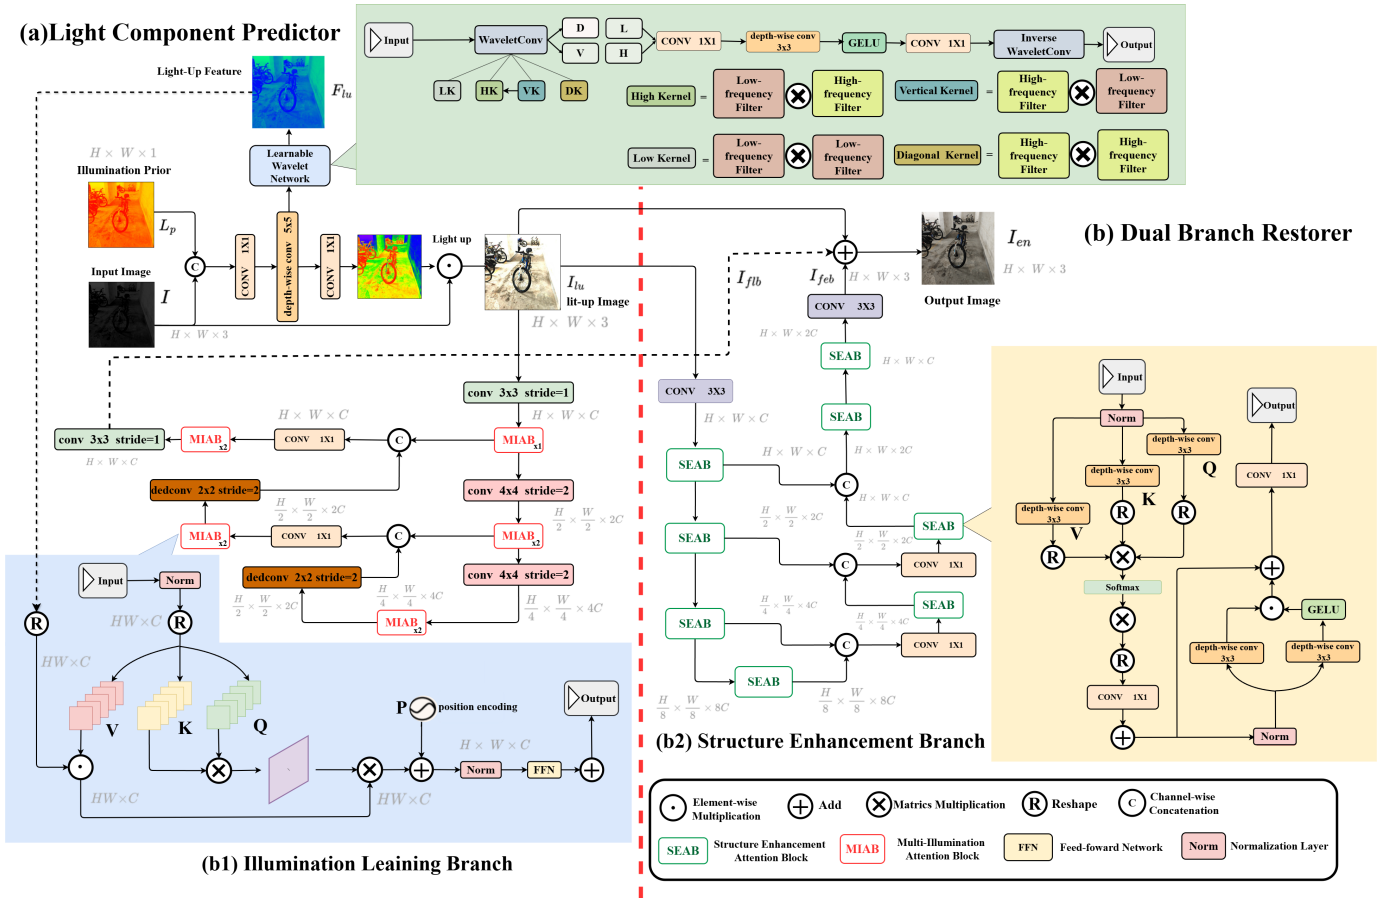

Fig. 3. The figure illustrates the detailed structure of our model, which consists of two main components: (a) the Light Component Predictor and (b) the Dual-Branch Restorer.

1) **Illumination Learning Branch:** This branch employs an encoder-decoder structure. The encoder handles the down-sampling process, while the decoder corresponds to up-sampling. Both processes are symmetric and occur in two stages. In the down-sampling path,  $I_{lu}$  undergoes a  $3 \times 3$  convolution, followed by a Multi-Illumination Attention Block (MIAB), and then a  $4 \times 4$  convolution (stride=2) to downscale the features. Two additional MIABs are applied, followed by another  $4 \times 4$  convolution (stride=2) to generate hierarchical features. The up-sampling path is symmetrically designed, using a deconvolution layer ( $2 \times 2$ , stride=2) to upscale the features. Skip connections are employed to mitigate information loss during down-sampling. The up-sampling branch outputs a residual image  $I_{flb} \in \mathbb{R}^{H \times W \times 3}$ . The core unit of the Illumination Learning Branch (ILB) is the Multi-Illumination Attention Block (MIAB), as shown in Figure.3(b1).

2) **Multi-Illumination Attention Block:** As shown in Figure.3(b1), the light-up feature  $F_{lu} \in \mathbb{R}^{H \times W \times C}$ , estimated by LCP, is fed into each MIAB. For clarity, Figure.3(b1) shows the attention mechanism at the largest scale, while smaller scales use  $4 \times 4$  convolutions (stride=2) to downscale  $F_{lu}$ , which is omitted for simplicity. This block treats a single-channel feature map as a token and computes attention.

The input feature  $F_{in} \in \mathbb{R}^{H \times W \times C}$  is reshaped into tokens  $X \in \mathbb{R}^{HW \times C}$ . Then,  $X$  is split into  $k$  heads:

$$X = [X_1, X_2, \dots, X_k],$$

where  $X_i \in \mathbb{R}^{HW \times d_k}$  and  $d_k = \frac{C}{k}$ , with  $i = 1, 2, \dots, k$ . Note that Figure.3(b1) illustrates the case for  $k = 1$ , omitting some details for simplicity. Each head undergoes a linear projection using fully connected layers without bias to produce query elements  $Q_i$ , key elements  $K_i$ , and value elements  $V_i$ :

$$Q_i = X_i W_{Q_i}^T, \quad K_i = X_i W_{K_i}^T, \quad V_i = X_i W_{V_i}^T,$$

where  $W_{Q_i}, W_{K_i}, W_{V_i} \in \mathbb{R}^{d_k \times d_k}$  are the learnable parameters of the fully connected layers, and  $T$  denotes the matrix transpose. Different regions within the same image often exhibit varying lighting conditions. The darker regions are typically associated with more pronounced distortions, making them more challenging to restore. In contrast, areas with better lighting conditions provide richer semantic context, which can facilitate the enhancement of darker regions. To leverage this, we introduce the light-up feature  $F_{lu}$ , which encodes lighting information and captures the interactions between regions with disparate lighting conditions. This feature is then used to guide the attention computation. In order to align with the shape of

$X$ , we reshape  $F_{lu}$  into  $Y \in \mathbb{R}^{HW \times C}$  and decompose it into  $k$  attention heads:

$$Y = [Y_1, Y_2, \dots, Y_k],$$

where  $Y_i \in \mathbb{R}^{HW \times d_k}$  for  $i = 1, 2, \dots, k$ . The self-attention for each head  $i$  is formulated as:

$$\text{Attention}(Q_i, K_i, V_i, Y_i) = (Y_i \odot V_i) \text{softmax} \left( \frac{K_i^T Q_i}{\alpha_i} \right),$$

where  $\alpha_i \in \mathbb{R}$  is a learnable parameter that adaptively scales the matrix multiplication. After concatenating the  $k$  heads, the result passes through a fully connected layer and is added to a positional encoding  $P \in \mathbb{R}^{HW \times C}$  (learnable parameters) to produce the output tokens  $X_{out} \in \mathbb{R}^{HW \times C}$ . Finally,  $X_{out}$  is reshaped to obtain the output feature  $F_{out} \in \mathbb{R}^{H \times W \times C}$ .

3) **Structure Enhancement Branch:** The input to the Structure Enhancement branch (Fig.3(b2)) is also  $I_{lu}$ . We first apply a convolution to extract low-level feature embeddings. The shallow features  $F_0$  are processed through a 4-level symmetric encoder-decoder framework, yielding deep features  $F_d \in \mathbb{R}^{H \times W \times 2C}$ . Each encoder-decoder level incorporates multiple Structure Enhancement Attention Blocks (SEAB), with the number of blocks progressively increasing from top to bottom to maintain computational efficiency. The encoder initially operates on the high-resolution input, systematically reducing the spatial dimensions while augmenting the channel capacity. Conversely, the decoder takes the low-resolution latent features  $F_l \in \mathbb{R}^{\frac{H}{8} \times \frac{W}{8} \times 8C}$  and iteratively reconstructs high-resolution representations. Skip connections concatenate encoder features with decoder features, and a  $1 \times 1$  convolution reduces the channel dimension (by half) at all levels except the top one. The SEAB aggregates low-level image features from the encoder with high-level features from the decoder. In the refinement stage, the deep features  $F_{de}$  are further enhanced at high spatial resolution. Finally, a convolution layer is applied to the refined features to generate the restored image  $I_{feb} \in \mathbb{R}^{H \times W \times 3}$ . The final restored image is obtained by adding the degraded image to  $I_{feb}$ .

The enhanced image  $I_{en}$  is derived by summing  $I_{lu}$ ,  $I_{flb}$ , and  $I_{feb}$ :

$$I_{en} = I_{lu} + I_{flb} + I_{feb}$$

4) **Structure Enhancement Attention Block:** The Structure Enhancement Attention Block (SEAB) operates on a layer-normalized tensor  $T \in \mathbb{R}^{H \times W \times C}$ . The block begins with the generation of query ( $Q$ ), key ( $K$ ), and value ( $V$ ) projections, which are enriched with local contextual information. This is accomplished through a two-step convolutional approach: first,  $1 \times 1$  convolutions are employed to capture pixel-wise cross-channel context, followed by  $3 \times 3$  depth-wise convolutions to encode spatial context at the channel level:

$$Q_{\mathcal{F}} = W_{\mathcal{D}}^Q W_{\mathcal{P}}^Q T, \quad K_{\mathcal{F}} = W_{\mathcal{D}}^K W_{\mathcal{P}}^K T, \quad V_{\mathcal{F}} = W_{\mathcal{D}}^V W_{\mathcal{P}}^V T,$$

where  $W_{\mathcal{P}}^{(\cdot)}$  denotes the  $1 \times 1$  point-wise convolution, and  $W_{\mathcal{D}}^{(\cdot)}$  represents the  $3 \times 3$  depth-wise convolution. The self-attention process is then defined as:

$$\hat{T}_{\mathcal{F}} = W_{\mathcal{P}} \text{Attention} \left( \hat{Q}_{\mathcal{F}}, \hat{K}_{\mathcal{F}}, \hat{V}_{\mathcal{F}} \right) + T, \quad (8)$$

$$\text{Attention} \left( \hat{Q}_{\mathcal{F}}, \hat{K}_{\mathcal{F}}, \hat{V}_{\mathcal{F}} \right) = \hat{V}_{\mathcal{F}} \cdot \text{Softmax} \left( \frac{\hat{K}_{\mathcal{F}}^T \hat{Q}_{\mathcal{F}}}{\beta_{\mathcal{F}}} \right), \quad (9)$$

where  $T$  and  $\hat{T}_{\mathcal{F}}$  represent the input and output feature maps, respectively, and  $\beta_{\mathcal{F}}$  is a learnable scaling parameter that controls the magnitude of the dot product between  $\hat{K}_{\mathcal{F}}$  and  $\hat{Q}_{\mathcal{F}}$  before the softmax operation. After performing element-wise multiplication with the illumination map  $L_{\mathcal{I}}$ , the resulting feature map undergoes two additional  $1 \times 1$  convolutions, followed by  $3 \times 3$  depth-wise convolutions. Finally, it passes through a  $1 \times 1$  convolution to output a feature map of the same size as the original input. This operation refines the image features, ensuring that the output preserves both spatial and contextual integrity, ultimately contributing to the enhancement of the restored image.

### C. Learnable Wavelet Module

To more effectively leverage frequency-domain information and preserve image details, we introduce the Learnable Discrete Wavelet Module, which is showed in Fig.3. By emphasizing high-frequency components, the module significantly improves the reconstruction of local details—such as fine textures and edges—that are often blurred or lost in conventional low-light enhancement methods.

1) **Learnable Discrete Wavelet Transform for Low-Light Image Enhancement:** For a 1D discrete signal  $g(u)$ , the wavelet function is defined as

$$\psi_{m,n}(u) = 2^{m/2} \psi(2^m u - n),$$

where  $m$  is the scaling factor,  $n$  is the translation factor, and the scaling function is defined as

$$\phi_{m,n}(u) = 2^{m/2} \phi(2^m u - n).$$

The signal decomposition is expressed as:

$$g(u) = \sum_{m>m_0} \sum_n e_{m,n} \psi_{m,n}(u) + \sum_n b_{m_0,n} \phi_{m_0,n}(u), \quad (3)$$

where  $e_{m,n} = \langle g(u), \psi_{m,n}(u) \rangle$  represents the detail coefficients (high-frequency components), and  $b_{m_0,n} = \langle g(u), \phi_{m_0,n}(u) \rangle$  represents the approximation coefficients (low-frequency components).

To recursively compute the wavelet coefficients, we apply high-pass and low-pass filters, denoted as:

$$e_{m+1,q} = \sum_n h_1[n-2q] b_{m,n}, \quad b_{m+1,q} = \sum_n h_0[n-2q] b_{m,n}, \quad (4)$$

where  $h_0$  and  $h_1$  are the low-pass and high-pass filters, respectively.

In the 2D case, the wavelet transform decomposes an image into four subbands: low-frequency ( $G_{ll}$ ), horizontal high-frequency ( $G_{lh}$ ), vertical high-frequency ( $G_{hl}$ ), and diagonal high-frequency ( $G_{hh}$ ). These subbands are obtained by taking

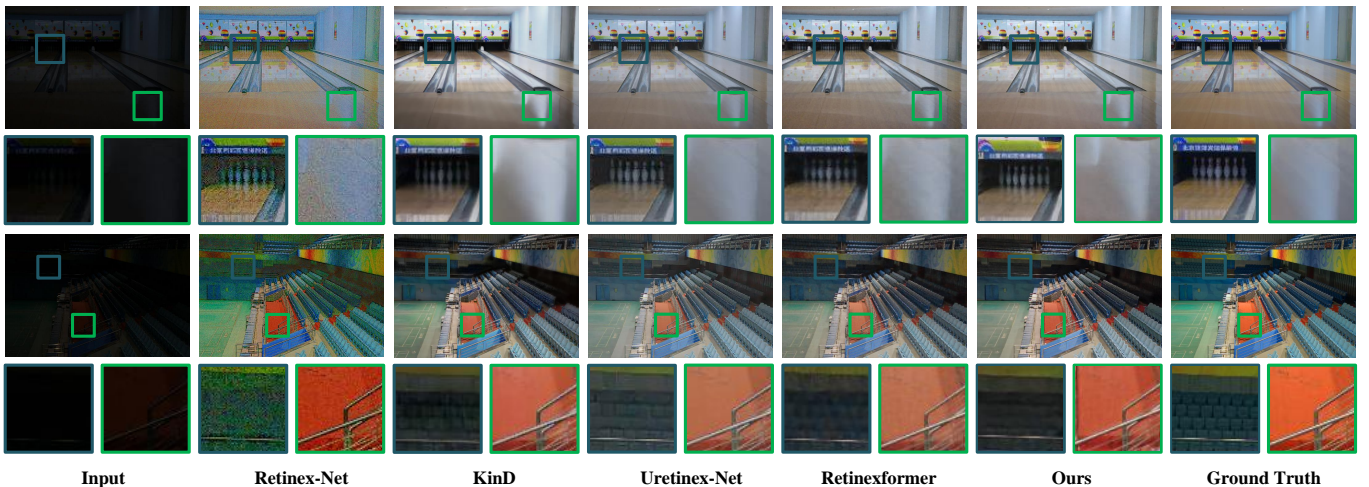

Fig. 4. The figure shows the qualitative experimental results on LOLv1. Our method effectively reduces color distortions and enhances lighting effects.

tensor products of the learnable 1D filters  $\vec{h}_0$  and  $\vec{h}_1$ , as follows:

$$G_{ll} = \vec{h}_0 \otimes \vec{h}_0^T, \quad G_{lh} = \vec{h}_0 \otimes \vec{h}_1^T, \quad (10)$$

$$G_{hl} = \vec{h}_1 \otimes \vec{h}_0^T, \quad G_{hh} = \vec{h}_1 \otimes \vec{h}_1^T, \quad (11)$$

$$K_g = \text{cat}(G_{ll}, G_{lh}, G_{hl}, G_{hh}). \quad (5)$$

Here,  $\otimes$  represents the outer product, and  $\text{cat}$  denotes the concatenation of the four subbands along the channel dimension. The resulting tensor  $K_g$  captures a multi-resolution representation of the image, which is then used for adaptive feature extraction.

2) **Advantages of Learnable Wavelet for Low-Light Enhancement:** The use of a learnable wavelet transform in the Light Component Predictor offers several key advantages for low-light image enhancement. First, it allows the network to separate fine high-frequency details, such as edges and textures, from the low-frequency illumination components of the image. This separation ensures that the network can effectively preserve important image details while simultaneously improving overall image quality. Unlike traditional methods that rely on fixed, predefined wavelet bases, our method utilizes learnable wavelet filters, enabling adaptive feature extraction tailored to the low-light enhancement task. This flexibility allows the model to better handle the challenges posed by low-light conditions, such as noise and blurred details, resulting in enhanced image sharpness and improved structure recovery.

#### IV. EXPERIMENTS

##### A. Datasets and Implementation details

We evaluated the performance of our model on standard benchmark datasets, specifically the LOL datasets [13] [14]. The LOL dataset consists of two versions: v1 and v2. The LOLv1 dataset includes 485 training pairs and 15 testing pairs, comprising a total of 500 image pairs, each containing both low-light and normal-light images. The majority of the images focus on interior scenes, and all images have a resolution of

400×600 pixels. The LOLv2 dataset is further divided into two subsets: LOLv2 Real and LOLv2 Synthetic. The training-to-test data ratio for LOLv2 Real is 689:100, and for LOLv2 Synthetic, it is 900:100. The distribution of data pairs and image sizes in LOLv2 is identical to those in LOLv1. Our

Fig. 5. This figure demonstrates the detailed effects of the module on the image. When the LWN module (a) is removed, there is a noticeable loss of texture preservation. Similarly, excluding the SEAB branch (b) results in a loss of crucial structural information. Our method (c), however, produces results that are visually closest to the target (d), with the most accurate preservation of both texture and structural details.

method was implemented in PyTorch and experiments were conducted on A10 and A800 GPUs running on a Linux system. We set the image resolution to 128×128 pixels. The batch sizes were set to 8 for LOLv1 and LOLv2 Synthetic, and 4 for LOLv2 Real. Standard data augmentation techniques, in-

cluding random rotation and flipping, were applied to enhance the training dataset. To minimize the loss, we employed the Adam optimizer.

### B. Evaluation Metrics

To evaluate the performance of our low-light image enhancement method, we employed two widely used image quality metrics: Peak Signal-to-Noise Ratio (PSNR) and Structural Similarity Index (SSIM). These metrics are commonly used in image enhancement tasks to assess noise levels and structural fidelity, respectively. A higher PSNR indicates superior image enhancement, while a higher SSIM signifies better preservation of high-frequency details and structural integrity.

The Peak Signal-to-Noise Ratio (PSNR) is defined as:

$$\text{PSNR} = 10 \cdot \log_{10} \left( \frac{R^2}{\text{MSE}} \right)$$

where  $R$  is the maximum possible pixel value of the image (usually 255 for 8-bit images), and MSE (Mean Squared Error) is given by:

$$\text{MSE} = \frac{1}{N \cdot M} \sum_{i=1}^N \sum_{j=1}^M (I(i, j) - K(i, j))^2$$

where  $I(i, j)$  and  $K(i, j)$  represent the pixel values of the enhanced image and the ground truth image, respectively, and  $N$  and  $M$  are the dimensions of the image.

The Structural Similarity Index (SSIM) is calculated as:

$$\text{SSIM}(x, y) = \frac{(2\mu_x\mu_y + C_1)(2\sigma_{xy} + C_2)}{(\mu_x^2 + \mu_y^2 + C_1)(\sigma_x^2 + \sigma_y^2 + C_2)}$$

where  $\mu_x$  and  $\mu_y$  are the mean intensities of the images  $x$  and  $y$ ,  $\sigma_x^2$  and  $\sigma_y^2$  are the variances of the images, and  $\sigma_{xy}$  is the covariance between the images.  $C_1$  and  $C_2$  are small constants used to stabilize the division with weak denominator values, usually set as:

$$C_1 = (k_1L)^2, \quad C_2 = (k_2L)^2$$

where  $L$  is the dynamic range of the pixel values (e.g., 255 for 8-bit images), and  $k_1$  and  $k_2$  are constants with typical values  $k_1 = 0.01$  and  $k_2 = 0.03$ .

### C. Comparison with other approaches

1) *Quantitative Comparisons*: In this work, we present a comprehensive evaluation of our method in comparison to several state-of-the-art (SOTA) techniques across both supervised and unsupervised paradigms, as detailed in Table I. The datasets employed for the comparative analysis include both synthetic and real-world data. For clarity, we define "supervised methods" as those trained with reference images, while "unsupervised methods" do not rely on reference images during training. Our method is compared against leading deep learning models, including LIME [23], MBLLEN [7], Retinex-Net [21], KinD [22], KinD++ [13], MIRNet [25], URetinex-Net [29], and Retinexformer [9]. The results demonstrate

that our DLEN model achieves substantial improvements in Peak Signal-to-Noise Ratio (PSNR), with average increases of 6.734, 6.142, 6.287, 3.878, 4.333, 0.838, 1.584, and 0.505 dB across the two benchmark datasets shown in Table I. Additionally, the SSIM values of our method slightly surpass those of other techniques.

2) *Qualitative Comparisons*: We performed an extensive set of qualitative experiments to visually assess the performance of our method in comparison to other state-of-the-art (SOTA) algorithms. As shown in Fig. 1, the color space recovery results demonstrate that our method closely approximates the ground truth images, highlighting the efficacy of our approach. Fig. 2 presents several enhanced sample images, and upon detailed inspection, it is evident that our enhanced images are virtually indistinguishable from the ground truth, indicating a high level of fidelity in preserving both texture and structural details.

A more detailed qualitative comparison between our method, DLEN, and other SOTA algorithms is presented in Figs. 4 and 6. Fig. 4 compares the results on the LOLv1 dataset, while Fig. 6 demonstrates performance on the LOLv2-real dataset. The results from previous methods reveal several notable deficiencies. For example, Retinex-Net [21] is prone to noise amplification, while KinD [22] tends to generate images with considerable underexposure. PairLie [36] exhibits overexposure in certain image regions, and ZeroRCE [26] suffers from pronounced noise and artifacts. In addition, Retinexformer [9] shows visible underexposure around the bowling ball in Fig. 4 and noticeable color distortion in the stadium area at the bottom of the image. In contrast, our DLEN model effectively addresses issues such as exposure management, color distortion, and noise reduction, yielding visually superior enhancement results.

### D. Ablation Study

We conduct ablation studies on three datasets: LOLv1, LOLv2-real, and LOLv2-syn. The term "w/o LWN" indicates the removal of the learnable wavelet network in the Illumination Estimator, while "w/o SEAB" refers to the removal of the SEAB branch, retaining only the core architecture. Compared to all other ablation configurations, our full setup achieves the highest PSNR and SSIM values. The "w/o LWN" configuration highlights the limitations of insufficient feature representation in the frequency domain, while "w/o SEAB", which uses only the basic Transformer architecture, suffers from a lack of enhanced structural information.

The visual results of our ablation study are shown in Fig. 5. Direct observation of Fig. 5 clearly reveals that the removal of the LWN module leads to a noticeable loss of texture preservation. Similarly, excluding the SEAB branch results in the loss of crucial structural information. In contrast, our method produces results that are visually closest to the target, effectively preserving both texture and structural details.

## V. CONCLUSION

In this paper, we proposed the Dual Light Enhance Network (DLEN) for low-light image enhancement, which introduces

Fig. 6. The above shows the qualitative experimental results on LOLv2-real. Our method effectively reduces color distortions and enhances lighting effects.

TABLE I  
QUANTITATIVE COMPARISONS ON LOL-v1 AND LOLv2-REAL

Methods	LOL-v1		LOLv2-real	
	PSNR $\uparrow$	SSIM $\uparrow$	PSNR $\uparrow$	SSIM $\uparrow$
<b>Supervised</b>				
LIME [23]	16.362	0.624	16.342	0.653
MBLLEN [7]	17.938	0.699	15.950	0.701
Retinex-Net [21]	17.188	0.589	16.410	0.640
KinD [22]	20.347	0.813	18.070	0.781
KinD++ [13]	20.707	0.791	16.800	0.741
MIRNet [25]	<b>24.140</b>	0.840	20.357	0.782
URetinex-Net [29]	21.450	0.795	21.554	0.801
Retinexformer [9]	23.932	0.831	21.230	0.838
DLEN(ours)	23.942	<b>0.841</b>	<b>22.230</b>	<b>0.854</b>
<b>Unsupervised</b>				
GenerativePrior [38]	12.552	0.410	13.041	0.552
Zero-RCE [26]	16.760	0.560	18.059	0.580
RUAS [28]	16.401	0.503	16.873	0.513
SCI [32]	14.864	0.542	15.342	0.521
PairLie [36]	19.691	0.712	19.288	0.684
NeRCO [35]	19.701	0.771	19.234	0.671
CLIP-LIE [37]	17.207	0.589	17.057	0.589

a novel architecture combining two distinct attention mechanisms that operate in both spatial and frequency domains. Through the incorporation of a learnable wavelet transform module and a dual-branch architecture, our model preserves high-frequency details and enhances edge and texture information, producing visually natural and high-quality enhanced images. Extensive experimental results on standard benchmarks demonstrate that DLEN outperforms state-of-the-art methods, achieving superior performance in terms of both quantitative

TABLE II  
ABLATION STUDY ON LOL-v1, LOLv2-REAL AND LOLv2-SYN

Methods	LOL-v1		LOLv2-real		LOLv2-syn	
	PSNR $\uparrow$	SSIM $\uparrow$	PSNR $\uparrow$	SSIM $\uparrow$	PSNR $\uparrow$	SSIM $\uparrow$
w/o LWN	23.463	0.836	<b>22.293</b>	0.853	25.788	0.933
w/o SEAB	22.824	0.820	21.261	0.833	24.991	0.924

metrics and qualitative visual quality. This work highlights the importance of simultaneously considering both spatial and frequency information for low-light image enhancement and provides a promising direction for future research in this area. Future work could explore the application of DLEN in real-time scenarios and the adaptation of the model to more diverse low-light environments, including extremely challenging cases such as night-time and foggy conditions.
