#### Abstract

Best-of-N (BoN) sampling, a common strategy for test-time scaling of Large Language Models (LLMs), relies on reward models to select the best candidate solution from multiple generations. However, traditional reward models often assign arbitrary and inconsistent scores, limiting their effectiveness. To address this, we propose a Pairwise Reward Model (Pairwise RM) combined with a knockout tournament for BoN sampling. Instead of assigning absolute scores, given one math problem, Pairwise RM evaluates two candidate solutions' correctness simultaneously. This approach eliminates the need for arbitrary scoring and enables crossvalidation of solutions through parallel comparison. In the knockout tournament, Pairwise RM conducts pairwise comparisons between candidate solutions and eliminates the incorrect ones iteratively. We construct PAIRWISE-443K, a large-scale dataset of 443K pairwise comparisons derived from NumiaMath and annotated using gemini-1.5-flash, and train the Pairwise RM via supervised fine-tuning. Experiments on MATH-500 and the Olympiad Bench demonstrate significant improvements over traditional discriminative reward models. And a 40% to 60% relative improvement is achieved on the top 50% challenging problems.

#### 1 Introduction

Recently, test-time scaling has garnered significant attention from the research community, as it draw a blueprint for the next stage of scaling of Large Language Models (LLMs) [\(Snell et al.,](#page-9-0) [2024;](#page-9-0) [Wu](#page-9-1) [et al.,](#page-9-1) [2024;](#page-9-1) [OpenAI,](#page-9-2) [2024\)](#page-9-2). One of the most common practice to achieve test-time scaling is to use reward models (RMs) to perform the Best-of-N (BoN) Sampling at test time [\(Wang et al.,](#page-9-3) [2023;](#page-9-3) [Lightman et al.,](#page-9-4) [2023;](#page-9-4) [Wang et al.,](#page-9-5) [2024b;](#page-9-5) [Zhang](#page-10-0) [et al.,](#page-10-0) [2024b;](#page-10-0) [Yuan et al.,](#page-10-1) [2024b\)](#page-10-1): the LLM generates N candidate solutions for a given problem, and a learned reward model, scoring each candidate solution, selects the best one as the final output. The

effectiveness of this strategy hinges on how accurate the score assigned by the reward model is to the candidate solutions.

However, assigning accurate and consistent scores is inherently challenging, even for human experts [\(Jonsson and Svingby,](#page-9-6) [2007;](#page-9-6) [Abdul Gafoor](#page-8-0) [and Jisha,](#page-8-0) [2014\)](#page-8-0). An experiment conducted in NeurIPS 2021 shows that for different human experts guided by the same rubric, the scores assigned to the same candidate paper can vary significantly [\(Beygelzimer et al.,](#page-8-1) [2021\)](#page-8-1). This limitation is particularly pronounced in reward models, which are typically trained to assign relative scores rather than absolute, meaningful scores [\(Lambert et al.,](#page-9-7) [2024;](#page-9-7) [Liu and Zeng,](#page-9-8) [2024\)](#page-9-8). As a result, the scores assigned by reward models are often arbitrary and inconsistent, hindering the performance of BoN sampling [\(Liu et al.,](#page-9-9) [2024;](#page-9-9) [Kim et al.,](#page-9-10) [2024\)](#page-9-10).

To address this limitation, we propose a Pairwise Reward Model (Pairwise RM) combined with a knockout tournament for BoN sampling. Instead of assigning absolute scores, Pairwise RMs evaluate two candidate solutions simultaneously, determining which one is better based on a predefined criterion. Specifically, inlining with existing work [\(Lightman et al.,](#page-9-4) [2023;](#page-9-4) [Wang et al.,](#page-9-3) [2023;](#page-9-3) [Snell et al.,](#page-9-0) [2024;](#page-9-0) [Wu et al.,](#page-9-1) [2024\)](#page-9-1), we use math reasoning tasks as the testbed to evaluate the performance of the Pairwise RM. The criterion for the Pairwise RM is to determine which of the two candidate solutions is correct. In this setting, our approach eliminates the need for arbitrary scoring and enables cross-validation of solutions through parallel comparison. To perform BoN sampling, we organize candidate solutions into a knockout tournament, where each pairwise comparison acts as a match. Rounds of matches are played until only one candidate remains, which is selected as the final output.

We construct PAIRWISE-443K, a large-scale dataset of 443K pairwise comparisons derived from **Question:** *If one equilateral triangle in a regular hexagon has a perimeter of 21 inches, what is the hexagon's perimeter?*

**Response** ■**:** *Each side of triangle is* 21 ÷ 3 = 7*. The hexagon, made of six such sides, has a perimeter of*  $6 \times 7 = 42$ 

**Response** ■**:** *The triangle's perimeter is 21. The hexagon, made of six such triangles, has a perimeter of*  $21 \times 6 = 126$ .

*Response* ■*: First, the triangle's perimeter is 21 (correct). Second, the hexagon is made of six such triangles, leading to*  $21 \times 6 = 126$  *(incorrect interpretation, mix up the area with perimeter). The final answer is incorrect.* Eliminated!

a) Input Prompt and Pairwise Comparison in our Pairwise Reward Model. b) Knockout with Pairwise RM.

Figure 1: An example of the knockout tournament with the Pairwise RM. Pairwise RM takes one question and two responses as the input prompt, and outputs the pairwise comparison results to determine the correctness of the responses. The Pairwise RM correctly identifies the first response as correct and the second response as incorrect, leading to the elimination of the second response. Such pairwise comparisons iteratively proceed in the knockout tournament until only one response remains. The final response is selected as the best candidate solution.

NumiaMath [\(LI et al.,](#page-9-11) [2024\)](#page-9-11) and annotated using gemini-1.5-flash. Using this dataset, we train the Pairwise RM via supervised fine-tuning. Experiments on MATH-500 and the Olympiad Bench demonstrate that Pairwise RM significantly outperforms traditional discriminative reward models. On the top 50% most challenging problems in MATH-500, Pairwise RM achieves a 40% to 60% relative improvement over the baseline. Furthermore, our method outperforms the recently proposed Critic Model(a.k.a generative reward model [\(Zhang et al.,](#page-10-0) [2024b\)](#page-10-0)) under the same computational budget.

In summary, our contributions are as follows:

- We propose a Pairwise Reward Model (Pairwise RM) combined with a knockout tournament for BoN sampling. This approach avoids the limitations of arbitrary scoring in traditional reward models and enables crossvalidation of candidate solutions.
- We release PAIRWISE-443K, a large-scale dataset for training pairwise reward models containing 443K annotated pairwise comparison, along with its construction pipeline.
- Experiments on MATH-500 and the Olympiad Bench demonstrate significant improvements compared to baselines in BoN sampling. Specifically, on the top 50% most difficult problems, Pairwise RM achieves a 40% to 60% relative improvement over baselines.

# 2 Preliminaries

Best-of-N Sampling in Math Reasoning Given a math problem  $x \in \mathcal{X}$  and the N candidate solutions  $\{y_1, y_2, \ldots, y_N\}$  sampled from a Large Language Model (LLM), the BoN Sampling aims to select the best candidate solution  $y^*$  from the N candidate solutions based on an external selection mechanism. Typically, there are two types of reward models (RMs) serving as the external selection mechanism: the Outcome Reward Model and the Process Reward Model.

Outcome Reward Model Given a math problem  $x$  and a candidate solution  $y$ , the Outcome Reward Model assigns a numerical score  $s(y)$  to the candidate solution y. The Outcome Reward Model selects the candidate solution with the highest score as the final output:

<span id="page-1-0"></span>
$$
y^* = \arg\max_{y \in \{y_1, y_2, \dots, y_N\}} s(y). \tag{1}
$$

The Outcome Reward Model is typically trained on a preference dataset  $D$ , consisting of pairs  $(x, y_c, y_r)$ , where  $y_c$  is the chosen response and  $y_r$  is the rejected response. The model is trained to assign a higher reward to  $y_c$  than to  $y_r$ , optimizing the following objective:

$$
\mathcal{L} = -\mathbb{E}\left[\log \sigma(R_{\psi}(x, y_c) - R_{\psi}(x, y_r))\right] \quad (2)
$$

 $\mathcal L$  is the loss function for preference learning indicating the probability of the chosen response  $y_c$ 

PAIRWISE COMPARISON

INPUT PROMPT being preferred over the rejected response  $y_r$ . This objective ensures that the reward model learns to identify responses that align better with human preferences.

**Process Reward Model** Given a math problem  $x$ and a corresponding candidate solution *, the Pro*cess Reward Model first requires to split the candidate solution  $y$  into a sequence of reasoning steps  ${a_1, a_2, \ldots, a_M}$ . The Process Reward Model assigns a numerical score  $s(a_i)$  to each reasoning step  $a_i$ . The score of the entire candidate solution  $y$  is the mean of the scores of all reasoning steps:

$$
s(y) = \frac{1}{M} \sum_{i=1}^{M} s(a_i).
$$
 (3)

The Process Reward Model selects the candidate solution with the highest score as the final output with the same mechanism as the Outcome Reward Model in Equation [1.](#page-1-0)

The Process Reward Model is typically trained on a dataset with process labels  $\mathcal{D}_{\text{proc}}$ , where each solution  $y$  to a problem  $x$ , the dataset contains a series of process labels  $\{l_1, l_2, \ldots, l_M\}$ , where  $l_i \in \{0, 1\}$  indicates whether the reasoning step  $a_i$ is correct or incorrect. Then the Process Reward Model is trained to predict the correctness of each reasoning step  $a_i$ .

# 3 Pairwise Reward Model and Knockout

In this section, we introduce the Pairwise RM and the knockout tournament, which are the core components of our proposed method for performing BoN Sampling at test time.

### 3.1 Pairwise Reward Model

**Definition** Given a math problem  $x$  and two candidate solutions  $y_1$  and  $y_2$ , the Pairwise RM is designed to simultaneously check the correctness of the two candidate solutions. Specifically, the Pairwise RM is trained to predict the correctness of the two candidate solutions, denoted as  $c_1$  and  $c_2$ , respectively.

$$
c_1, c_2 = \text{PairwiseRM}(x, y_1, y_2), \quad (4)
$$

where  $c_1, c_2 \in \{0, 1\}$  indicate whether the candidate solutions  $y_1$  and  $y_2$  are correct or incorrect.

Implementation Inspired by the Generative Reward Model (GenRM) [\(Zhang et al.,](#page-10-0) [2024b\)](#page-10-0) and LLM-as-a-Judge [\(Zheng et al.,](#page-10-2) [2023\)](#page-10-2), we implement the Pairwise RM as a generative model. Specifically, given a math problem  $x$  and two candidate solutions  $y_1$  and  $y_2$ , the Pairwise RM first generates a reasoning text using chain-of-thought [\(Wei](#page-9-12) [et al.,](#page-9-12) [2022\)](#page-9-12) to verify the correctness of the two candidate solutions. Based on the reasoning text, the Pairwise RM then predicts the correctness of the two candidate solutions by directly generating the correctness labels  $c_1$  and  $c_2$ . The detailed prompt for performing pairwise verification with chain-ofthought is provided in Table [4](#page-12-0) in the Appendix.

#### 3.2 Knockout Tournament

To perform BoN Sampling with the Pairwise RM, we introduce a knockout tournament to select the best candidate solution.

<span id="page-2-0"></span>

Partition  $Y$  into k teams, where members of a team share the same final answer.

### Step 2: Initialize the knockout pool

Add all  $N$  candidates to the initial pool  $P$ .

```
Step 3: Perform the knockout rounds
while |\mathcal{P}| > 1 do
    Pair each candidate y_i with an unpaired
     y_i from a different team.
    Remove y_i and y_j from P.
    foreach pair (y_i, y_j) do
        Compute correctness scores c_i, c_jusing PairwiseRM(x, y_i, y_j).
        if c_i > c_j then
         |y_i| advances.
        else if c_j > c_i then
            y_i advances.
        else if c_i, c_j both correct then
            Randomly select one to advance.
         \overline{\phantom{a}}else
         \perp Both incorrect and eliminated.
    Add advancing candidates back to P.
```
Step 4: Return the best solution Output the last remaining y in  $P$  as  $y_{best}$ .

Specifically, we first group the  $N$  candidate solutions into  $k$  teams, where candidates that share the same answer are placed in the same team. Then, we pair up the candidate solutions from each team to compete with candidate solutions from other teams. In each match, only the candidate solution that receives the correct label from the Pairwise RM advances to the next round. If both candidate solutions receive the correct label, one is randomly selected to advance. This process continues until only one candidate solution remains or early termination occurs when all candidate solutions are from the same team. The detailed procedure of the knockout tournament is shown in Algorithm [1.](#page-2-0)

# <span id="page-3-1"></span>4 PAIRWISE-443K dataset collection

To train the Pairwise RM, we collect a largescale dataset named PAIRWISE-443K, which contains 443M annotated pairwise comparisons derived from NumiaMath [\(LI et al.,](#page-9-11) [2024\)](#page-9-11) with gemini-1.5-flash. In the following, we describe the detailed procedure of collecting the PAIRWISE-443K dataset.

### 4.1 Dataset Format

Since the Pairwise RM is designed as a generative model to judge the correctness of candidate solutions, the training dataset has the same format as the one for Supervised Fine-tuning, consisting of prompt-completion pairs. Specifically, each prompt is constructed by filling the template shown in Table [4](#page-12-0) with a math problem  $x$  and two candidate solutions  $y_1$  and  $y_2$ . The completion is a chain-of-thought reasoning text that verifies the correctness of the two solutions and provides the correctness labels  $c_1$  and  $c_2$ .

### 4.2 Math Problem Collection

We first collect math problems from the Numia-Math dataset [\(LI et al.,](#page-9-11) [2024\)](#page-9-11), which contains 860K problems ranging from high school math exercises and international mathematics olympiad competition problems. Because these data are primarily collected from online exam paper PDFs and mathematics discussion forums, we remove low-quality problems with messy formatting, OCR errors, or missing answers. We also remove multiple-choice (MCQ) and True/False questions to avoid random guessing in candidate solutions. Following community conventions, we remove proof problems as well, due to the difficulty of verifying candidate solutions. The detailed filtering criteria are listed in Table [5](#page-13-0) of the Appendix.

# 4.3 Candidate Solution Generation

For each math problem x, we generate  $k = 24$  candidate solutions  $\{y_1, y_2, \ldots, y_k\}$  using LLaMA-

Table 1: Statistics of the datasets before and after filtering. AMC-related datasets shrink significantly because most AMC tasks are multiple-choice.

<b>Dataset</b>	<b>Original Count</b>	<b>Filtered Count</b>
<b>AMC/AIME</b>	4,070	289
AoPS Forum	30,192	9,017
Chinese K-12	276,554	63,779

<b>ORCA</b> Math	153,314	149,550
Synthetic AMC	62,108	94
Synthetic Math	167,874	136,921
<b>Total</b>	859,494	425,943

3.1-8B-instruct. We employ the same four-shot in-context examples for all problems as the prompt. The candidate solutions are decoded with a temperature of 1.0 and a Top-P value of 0.5 to balance diversity and quality.

#### 4.4 Pairwise Verification Annotation

We use gemini-1.5-flash to annotate the Pairwise RM training data on the NumiaMath dataset. To align the generated training data distribution with the solution-comparison distribution in the knockout tournament, we conduct a knockout tournament for each math problem  $x$  and its candidate solutions  $\{y_1, y_2, \ldots, y_k\}$  to select the best solution  $y_{best}$ . During the knockout tournament, we record all pairwise comparisons among candidate solutions and retain only those comparisons that correctly judge solution correctness for the Pairwise RM. Specifically, due to cost considerations, we only run the knockout tournament for questions whose candidate solutions are not all correct or all incorrect. As a result, we conducted 343K tournaments and recorded 2.2M comparisons. Among these, 1.3M correctly evaluated both candidate solutions and were used as raw training data for the Pairwise RM. Finally, we filtered out samples where the response did not strictly follow the instructions in Table [4,](#page-12-0) ending up with 443K training samples for the Pairwise RM.

### 5 Experiments

<span id="page-3-0"></span>In this section, we demonstrate the effectiveness of the Pairwise RM and the knockout tournament in performing BoN Sampling at test time. We first introduce the experimental setup, including the dataset, evaluation metrics, and baselines. Then, we present the experimental results and analysis.

<span id="page-4-0"></span>Table 2: Different reward models' best-of-N sampling performance on MATH-500 and Olympiad Bench with three different LLMs: Llama-3.1-8B-Inst, Qwen-2.5-7B-Inst, and Llama-3.1-70B-Inst. The results are reported in terms of accuracy. The pass@1 accuracy of these three LLMs are 42.0, 73.6, and 59.2 on MATH-500, and 12.3, 35.7, and 25.9 on Olympiad Bench, respectively. @16, @32, and @64 denote the accuracy with Best-of-16, Best-of-32, and Best-of-64 sampling, respectively. The best results are in bold, and the second-best results are underlined.

# 5.1 Experimental Setup

Dataset We evaluate BoN Sampling on MATH-500 [\(Hendrycks et al.,](#page-8-2) [2021\)](#page-8-2) and Olympiad Bench [\(He et al.,](#page-8-3) [2024\)](#page-8-3) to coverage from the highschool-level math problems to the olympiad-level math problems. To study the generalizability of our Pairwise RM, we test it with three LLMs that have different capabilities and come from different model families: Llama-3.1-8B-Instruct [\(AI@Meta,](#page-8-4) [2024\)](#page-8-4), Llama-3.1-70B-Instruct [\(AI@Meta,](#page-8-4) [2024\)](#page-8-4), and Qwen2.5-7B-Instruct [\(Qwen Team,](#page-9-13) [2024\)](#page-9-13).

Training Details We use Qwen2.5-7B-Instruct as the base model and perform supervised fine-tuning on our PAIRWISE-443K dataset to obtain the Pairwise RM. We set the learning rate to  $1 \times 10^{-5}$  with the Adam optimizer and a batch size of 128. The model is trained for 8 epochs.

Baselines We compare our Pairwise RM with both outcome and process reward model, which is trained to assign a score to each candidate solution and then select the candidate solution with the highest score as the final output. For the Outcome Reward Model, we use EurusRM-7B [\(Yuan et al.,](#page-9-14) [2024a\)](#page-9-14), SkyworkRM-Llama3.1- 8B [\(Liu and Zeng,](#page-9-8) [2024\)](#page-9-8), and ArmoRM-Llama3- 8B [\(Gao et al.,](#page-8-5) [2024b\)](#page-8-5) as representatives of stateof-the-art outcome reward models. For the Process Reward Model, we leverage three off-theshelf open-source models: Math-Shepherd [\(Wang](#page-9-3) [et al.,](#page-9-3) [2023\)](#page-9-3), RLHFlow-8B-Mistral-Data, and RLHFlow-8B-Deepseek-Data [\(Dong et al.,](#page-8-6) [2024\)](#page-8-6). For fair comparison, we also reimplement the Math-Shepherd model with MCTS data generated by Llama-3.1-8B-Instruct, denoted as RLHFlow-8B-LLaMA-Data. We select the candidate solution with the highest reward-model score as the final output of BoN Sampling. Moreover, we include a majority-voting baseline, which selects the candidate solution that receives the most votes from the

<span id="page-5-0"></span>

the MATH-500, generated by (a) LLaMA-3.1-70B-Instr and (b) LLaMA-3.1-8B-Instr respectively. The Process RM Figure 2: Comparsion between Process RM, Outcome RM and Pairwise RM on the different difficulty percentile of and Outcome RM here are EurusRM-7B and RLHFlow-8B-DS-Data, respectively. As shown in the figure, except for the easiest problems, the Pairwise RM consistently outperforms the Process RM and Outcome RM. Specifically, the hardest 50% problems, the Pairwise RM achieves a 40% to 60% relative improvement compared to the Process RM and Outcome RM.

N candidate solutions as the final output.

# 5.2 Results

Experimental results are shown in Table [2.](#page-4-0) Our proposed Pairwise RM consistently outperforms the baseline models, including majority voting, on all datasets and across all generation models. Specifically, the Pairwise RM achieves an average improvement of 6.7% on MATH-500 and 3.9% on Olympiad Bench compared to the strongest baseline model (excluding majority voting). Interestingly, majority voting performs better than the baseline reward model on MATH-500, indicating that the existing reward model may not be robust enough to assign scores to candidate solutions. These results align with the findings in RM-Bench [\(Liu et al.,](#page-9-9) [2024;](#page-9-9) [Kim et al.,](#page-9-10) [2024\)](#page-9-10), where the discriminative reward model fails to robustly and stably determine the correctness of candidate solutions.

### 5.3 Difficulty Analysis

To further investigate scenarios in which the Pairwise RM outperforms the baseline reward model, we analyze the performance of the Pairwise RM and the baseline reward model on math problems with different levels of difficulty. We define the difficulty of a math problem as the fraction of incorrect answers among the candidate solutions:

$$
Difficulty = \frac{\#incorrect \ answers}{\#candidate \ solutions}.
$$
 (5)

Specifically, we calculate this difficulty when the number of candidate solutions is  $n = 64$ . We then divide the math problems into four percentile groups based on their difficulty level and evaluate the performance of the Pairwise RM and baseline models on each percentile in the MATH-500 dataset. Figure [2](#page-5-0) shows the results. Except for the easiest problems, the Pairwise RM consistently outperforms the baseline models across all difficulty levels. On the challenging problems (Difficulty  $> 0.5$ ), the Pairwise RM achieves a relative improvement of 40% to 60% over the baseline models. These findings indicate that the Pairwise RM has strong potential to enhance BoN Sampling on challenging math problems.

#### 6 Comparison with Critic Model

Critic Model [\(Gao et al.,](#page-8-7) [2024a;](#page-8-7) [McAleese et al.,](#page-9-15) [2024\)](#page-9-15), also known as LLM-as-a-Judge [\(Zheng](#page-10-2) [et al.,](#page-10-2) [2023;](#page-10-2) [Bai et al.,](#page-8-8) [2023\)](#page-8-8), is a recent approach that uses one LLM to critique another LLM's response to a given prompt. These methods aim to imitate the human judgment process in instructionfollowing settings by evaluating how well a response meets the user's prompt.

Recently, Critic Model has also been applied to the math and code reasoning domains to verify the correctness of candidate solutions and to assign numerical scores. This setting is similar to that of the Pairwise RM because both methods verify whether candidate solutions are correct. The difference is that Pairwise RM verifies two candidate solutions simultaneously, whereas the Critic Modelverifies them one by one. In this section, we investigate the effectiveness of the Pairwise RM and the Critic Modelfor correctness verification and Best-of-N Sampling at test time.

# <span id="page-6-1"></span>6.1 Comparison on Correctness Verification

Here, we compare the performance of the Pairwise RM and the Critic Model on the task of correctness verification. Specifically, given one question and two candidate solutions, the Pairwise RM and the Critic Modelare asked to judge the correctness of these two solutions. For a fair comparison, we first train a Pairwise RM and a Critic Model with the same computational budget and training data. In particular, we use the same questions from the MATH-500 training set [\(Hendrycks](#page-8-2) [et al.,](#page-8-2) [2021\)](#page-8-2) and the same candidate solutions generated by Llama-3.1-8B-Instruct [\(AI@Meta,](#page-8-4) [2024\)](#page-8-4) to build the training data for both Critic Modeland Pairwise RM. Because one training example for the Pairwise RM includes two candidate solutions, the training data for the Critic Modelends up being twice as large. All other training details follow Section [5.1.](#page-3-0)

After training, we evaluate the Pairwise RM and the Critic Modelon correctness verification with the MATH-500 and Olympiad datasets. Specifically, we sample 8,000 candidate solutions from both datasets to form the test set for the Critic Model. To avoid potential bias, these candidate solutions are generated by Qwen-2.5-7B-Instruct [\(Qwen Team,](#page-9-13) [2024\)](#page-9-13) using the test split. We then pair each solution with another solution that leads to a different answer for the same question, yielding 4,000 pairs of candidate solutions for evaluating the Pairwise RM.

The results are shown in Table [3.](#page-6-0) As shown in Table [3,](#page-6-0) the Pairwise RM outperforms the Critic Modelon both MATH-500 and Olympiad datasets. This finding suggests that pairwise verification in the Pairwise RM is more effective than singlesolution verification in the Critic Modelwhen judging correctness. Notably, in the more challenging Olympiad dataset, the Pairwise RM achieves a

<span id="page-6-0"></span>Table 3: Comparison of the Pairwise RM and LLM-asa-Judge on the MATH-500 and Olympiad datasets on correctness verification task. Candidates are generated by Qwen-2.5-7B-Instruct. Accuracy is reported.

Model		MATH Olympiad Avg.	
LLM-as-a-Judge	67.7	56.9	62.3
Pairwise RM	70.4	64.2	67.3

vote/ Prob Score bewteen Pairwise RM on BoN sam-Figure 3: Comparison of the Critic Model with Majority pling. The x-axis represents the number of candidates in the BoN sampling, and the y-axis represents the accuracy

larger improvement compared to MATH-500, highlighting the potential of the Pairwise RM on difficult math problems.

#### 6.2 Comparison on Best-of-N Sampling

As mentioned in Section [6.1,](#page-6-1) the main difference between the Pairwise RM and the Critic Modellies in the verification process. Pairwise RM verifies the correctness of two candidate solutions simultaneously, whereas the Critic Modelverifies them one by one. This difference makes it difficult to use the Critic Modelfor BoN Sampling at test time. When two candidate solutions with different answers are both verified as correct by the Critic Model, it is unclear which is better. In contrast, the Pairwise RM can directly compare the correctness of two candidate solutions and select the better one. To enable the Critic Modelto perform BoN Sampling at test time, we propose two solutions:

Combine with Majority Voting One option is to combine the Critic Modelwith majority voting. Specifically, the Critic Modelverifies the correctness of each candidate solution and removes those marked incorrect. Majority voting is then applied to the remaining candidate solutions to select the final output.

<span id="page-7-0"></span>

<b>Problem:</b> A regular hexagon can be divided into six equilateral triangles. If the perimeter of one of the triangles is 21 inches, what is the perimeter, in inches, of the regular hexagon?		
<b>Solution 1</b> : Since the perimeter of the triangle is 21, each side of the triangle has length $\frac{21}{3} = 7$ . The hexagon is made up of six of these triangles, so the perimeter of the hexagon is $6 \cdot 7 = 42$ . So the final answer is 42.		
<b>Generative RM</b> correctness score: 0.0006	<b>Pairwise RM</b> correctness check: True	
<b>Solution 2:</b> Since the perimeter of one of the triangles is 21 inches, the side length of the triangle is $\frac{21}{3} = 7$ inches. Since there are six equilateral triangles, the perimeter of the hexagon is six times the side length of one triangle, which is $6 \cdot 7 = 42$ inches. So the final answer is   42  .		
<b>Generative RM</b> correctness score: 0.9999	<b>Pairwise RM</b> correctness check: True	

Figure 4: An comparison example of the generative reward model (Generative RM) and the Pairwise RM (Pairwise RM). Both models are asked to check the correctness of the two correct solution for the math problem. The Generative RM assigns drastically different correctness scores to the two solutions (0.0006 vs. 0.9999), highlighting its inconsistency. In contrast, the Pairwise RM consistently identifies both solutions as correct.

Use Probabilistic Score Another approach is to use the probabilistic score assigned by the Critic Modelto each candidate solution. Concretely, the Critic Modelis prompted to generate a token "correct" or "incorrect" in its reasoning text to indicate the solution's correctness. [Zhang et al.](#page-10-0) [\(2024b\)](#page-10-0) suggests that the probability of generating the token "correct" can be used as the score for each candidate solution. The solution with the highest score is then chosen as the final output.

To prevent data leakage, we use the MATH-500 test split and candidate solutions generated by Qwen-2.5-7B-Instruct [\(Qwen Team,](#page-9-13) [2024\)](#page-9-13) to evaluate the Pairwise RM and the Critic Modelon BoN Sampling. For a fair comparison, we reuse the Critic Model and Pairwise RM trained in Section [6.1](#page-6-1) to perform BoN Sampling.

As shown in Figure [3,](#page-6-2) the Pairwise RM consistently outperforms the Critic Modelon the MATH-500 dataset. This result demonstrates that, under the same training budgets, the Pairwise RM is more effective at selecting the best candidate solution than the Critic Model. Another noteworthy observation is that the Critic Model with a Probabilistic Score performs worse than the Critic Model with Majority Voting. Upon closer examination, we find that the Critic Model tends to assign highly polarized scores to candidate solutions. As shown in Figure [4,](#page-7-0) for two similar candidate solutions, the probabilistic scores assigned by the Critic Model differ substantially. This finding suggests that the probabilistic scores assigned by the Critic Model may suffer from the same robustness and stability issues as discriminative reward models [\(Liu et al.,](#page-9-9) [2024;](#page-9-9) [Kim et al.,](#page-9-10) [2024\)](#page-9-10).

# 7 Related Work

#### 7.1 Test Time Scaling and Best-of-N Sampling

Test time scaling has attracted considerable attention since OpenAI released their first reasoning model, o1 [\(OpenAI,](#page-9-2) [2024\)](#page-9-2). The core idea behind test time scaling is to allocate additional computational resources at inference time to improve a model's performance on complex reasoning tasks, such as math problems [\(Snell et al.,](#page-9-0) [2024;](#page-9-0) [Wu](#page-9-1) [et al.,](#page-9-1) [2024\)](#page-9-1). Several methods have been proposed to perform test time scaling, including BoN Sampling [\(Wang et al.,](#page-9-3) [2023;](#page-9-3) [Lightman et al.,](#page-9-4) [2023;](#page-9-4) [Wang et al.,](#page-9-5) [2024b;](#page-9-5) [Zhang et al.,](#page-10-0) [2024b\)](#page-10-0), Monte Carlo Tree Search [\(Zhang et al.,](#page-10-3) [2024a;](#page-10-3) [Gao et al.,](#page-8-5) [2024b\)](#page-8-5), and the long-chain-of-thought [\(Min et al.,](#page-9-16) [2024;](#page-9-16) [Qwen Team, Alibaba,](#page-9-17) [2023\)](#page-9-17). Among these methods, BoN Sampling is the most naive and intuitive approach, where the model generates  $N$  candidate solutions for a given problem, and a learned reward model selects the best one as the final output.

### 7.2 Reward Models and Critic Models

Reward models (RMs) in language modeling are typically trained to assign numerical scores to responses generated by LLMs [\(Lambert et al.,](#page-9-7) [2024;](#page-9-7) [Liu et al.,](#page-9-9) [2024\)](#page-9-9). They are used to guide generation by providing feedback on the quality of the responses during training and inference [\(Wang et al.,](#page-9-18) [2024a;](#page-9-18) [Lightman et al.,](#page-9-4) [2023;](#page-9-4) [Wang et al.,](#page-9-5) [2024b\)](#page-9-5). Critic Models [\(Gao et al.,](#page-8-7) [2024a;](#page-8-7) [McAleese et al.,](#page-9-15) [2024;](#page-9-15) [Zheng et al.,](#page-10-2) [2023;](#page-10-2) [Li et al.,](#page-9-19) [2024\)](#page-9-19) is another line of work that provides feedback to LLMs by judging the quality of generated responses. Specifically, in reasoning domain such as math or code, Critic Models are used to verify the correctness of candidate solutions [\(Gao et al.,](#page-8-7) [2024a;](#page-8-7) [McAleese](#page-9-15)

[et al.,](#page-9-15) [2024\)](#page-9-15). In this regard, the Critic Models can be viewed as generative reward models [\(Zhang](#page-10-0) [et al.,](#page-10-0) [2024b\)](#page-10-0), which provides textual feedback rather than numerical scores. Compared to ours, Pairwise RM verifies the correctness of two candidate solutions simultaneously, while Critic Models verify them one by one.

# 8 Conclusion

In this work, we propose a Pairwise Reward Model (Pairwise RM) combined with a knockout tournament for BoN Sampling. Pairwise RM evaluates two candidate solutions simultaneously, eliminating the need for arbitrary scoring and enabling cross-validation of solutions through parallel comparison. In the knockout tournament, Pairwise RM conducts pairwise comparisons between candidate solutions and eliminates the incorrect ones iteratively. We construct a large-scale dataset of 443K pairwise comparisons for training the Pairwise RM. Experiments on MathOlympiad demonstrate that the Pairwise RM significantly outperforms baseline reward models. Our work provides a new perspective on how to perform BoN Sampling at test time and can potentially be applied to other reasoning tasks beyond math problems.

# Limitation

The main limitation of the proposed method lies on the inference time. To conduct the BoN Sampling with the Pairwise RM, serval rounds of pairwise verification are required to select the best candidate solution. This process is time-consuming and may not be suitable for latency-sensitive applications. However, the proposed method can be potentially accelerated by parallel computing or other optimization techniques to reduce the inference time. For example, the multiple pairwise verification can easily be parallelized to multiple GPUs to speed up the inference process since they are independent of each other. Moreover, with popularization of the inference-time scaling, it is a common practice to increase the computational resources to improve the performance of the model in solving complex reasoning tasks like math problems [\(Snell et al.,](#page-9-0) [2024;](#page-9-0) [Wu et al.,](#page-9-1) [2024\)](#page-9-1).

# Ethical Considerations

In this work, all the data and models are acquired from public datasets and pre-trained models, and no human subjects are involved in the experiments. Considering the potential hallucination and bias in the pre-trained models, it is worth nothing that the user should be cautious when applying the proposed method to real-world applications such as use Pairwise RM to check human student's homework in the educational system.

### Future Work

#### Application in Reinforcement Learning

In this work, we mainly focus on how to perform the BoN Sampling at test time with the Pairwise RM. This experiment setting follows the existing work [\(Wang et al.,](#page-9-3) [2023;](#page-9-3) [Lightman et al.,](#page-9-4) [2023;](#page-9-4) [Wang et al.,](#page-9-5) [2024b;](#page-9-5) [Zhang et al.,](#page-10-0) [2024b\)](#page-10-0) and helps us to compare the performance of the Pairwise RM with baseline models and verify the effectiveness of the proposed method. However, the Pairwise RM can also be applied at the Reinforcement Learning (RL) training stage to improve the performance of the model in solving complex reasoning tasks like math problems. To apply in the training stage, the Pairwise RM need to assign a numerical score to the candidate solutions just like the discriminative reward model [\(Lambert et al.,](#page-9-7) [2024;](#page-9-7) [Liu et al.,](#page-9-9) [2024\)](#page-9-9). Such a numerical score could acquired by the winning rate of the candidate solutions in the knockout tournament, which can be used as the reward signal to guide the training of the model. In the future, we plan to explore the application of the Pairwise RM in the RL training stage to improve the performance of the model in solving complex reasoning tasks like math problems.

# Alternative Tournament Strategies

In this work, we introduce the knockout tournament to select the best candidate solution, where the candidate solutions are viewed as players in the tournament and each pairwise comparison is viewed as a match between two players. The main reason for choosing the knockout tournament is that it is one of the most naive tournament design that could select the best candidate under time complexity  $O(N)$ , where N is the number of candidate solutions. It worth noting that there are tons of alternative tournament strategies that could be used to select the best candidate solution, such as the round-robin tournament, the Swiss-system tournament, and the double-elimination tournament [\(De](#page-8-9)[vriesere et al.,](#page-8-9) [2024\)](#page-8-9) Such alternative tournament strategies could be potentially used to improve the performance of the Pairwise RM in selecting the best candidate solution, and we plan to explore the application of the alternative tournament strategies in the future work.

# Potential Improvement

Due to the computational limitation and resource constraints, there are several potential improvements that could be made to further improve the performance of the Pairwise RM.

- Bigger Model Capacity: Due to the computational limitation, although we presents a promising and scalable dataset contruction in Section [4,](#page-3-1) the Pairwise RM is trained with the Qwen-2.5-7B-Instr, which is a relatively small model compared to the state-of-the-art models like the Qwen-2.5-70B-Instr, LLaMA-3.1-70B-Instr and QwQ-32B. According to the Chinchilla Law [\(Hoffmann et al.,](#page-8-10) [2022\)](#page-8-10), under the same training data and training time, a model with larger capacity can achieve better performance than a model with smaller capacity.
- More Data Scaling Dimension: The Pairwise RM is trained with the PAIRWISE-443K dataset, which contains 343K training data for the Pairwise RM. Now there are two directions to further improve the performance of the Pairwise RM: 1) use more models rather

than only LLama-3.1-8B-Instruct to generate the candidate solutions, and 2) Use more models rather than only gemini-1.5-flash to annotate the training data. This two directions could potentially magnitudes the size of the training data and improve the performance of the Pairwise RM.

• Long-Cot Base Model: The Pairwise RM is trained with the Qwen-2.5-7B-Instruct. Considering the recent success of the Long-Cot models such as the QwQ-32B [\(Qwen Team,](#page-9-17) [Alibaba,](#page-9-17) [2023\)](#page-9-17) in reasoning task, it is worth exploring the application of the Pairwise RM with the Long-Cot models to further improve the performance of the Pairwise RM.

# Prompt Templates

#### Math Problem Filtering Criteria

<span id="page-12-0"></span>Table 4: Prompt Template for Pairwise RM, the {question}, {response a}, and {response b} are placeholders for the math question, response A, and response B, respectively.

#### Task Objective:

Evaluate the correctness of two responses (Response A and Response B) to a given math question. Perform a step-by-step verification of each response's accuracy. After completing the step-by-step checks, provide a final correctness judgment for each response.

#### Steps to Follow:

#### 0. Extract Answers from both Responses:

- Read and both responses to identify the final answers provided.

- If the responses provide different answers, make sure there are is no possible way that both responses can be correct. It must be the case that one response is correct and the other is incorrect or both are incorrect.

#### 1. Step-by-Step Verification of Correctness:

- For each response (Response A and Response B):

Carefully examine each step of the solution provided. Check the following: - Mathematical accuracy: Ensure all calculations, algebraic simplifications,

and mathematical operations are correct. - Logical consistency: Verify that each step follows logically from the previous

one and that the reasoning is sound. - Completeness: Make sure that all necessary steps are included to fully solve

the problem and reach the final answer.

While performing this step-by-step evaluation, refer to the Additional Tips section for helpful techniques to validate each response's accuracy.

Attention: When checking the correctness of a single step, you should never first conclude the correctness of this step (for example, \*"This step is incorrect because..."\* is strictly forbidden). You should neutrally check this step, provide evidence about its correctness, and then finally draw a conclusion about the correctness of this step. In other words, you should first employ the techniques in Additional Tips to check the correctness of this step, and then draw a conclusion about the correctness of this step.

#### 2. Final Conclusion:

- After completing the step-by-step verification for each response, sum up the information you have now, then finally determine whether each response's answer is correct or incorrect.

- Provide the final judgment for each response, the output should in-closed with the following tags:

- If Response A's answer is correct:
- <resp\_a\_judge>Correct</resp\_a\_judge>
- If Response A's answer is incorrect:

<resp\_a\_judge>Incorrect</resp\_a\_judge>

- If Response B's answer is correct:
- <resp\_b\_judge>Correct</resp\_b\_judge>
- If Response B's answer is incorrect:
- <resp\_b\_judge>Incorrect</resp\_b\_judge>

- Note: The responses A and response B can be either correct or incorrect, or both correct, or both incorrect. You should provide the final judgment for each response. There is no guarantee that at least one response is correct or incorrect.

#### Additional Tips:

- Key Validation Techniques (to apply during Step 1):

- Re-derive Key Parts of the Solution: Independently calculate or derive crucial steps of the solution to verify their correctness.

- Verify Calculations: Double-check all mathematical operations (e.g., addition, multiplication, division) to confirm accuracy.

- Compare Responses: If needed, compare similar steps between Response A's and Response B's answers to identify discrepancies or inconsistencies.

#### - The final output format should be as follows:

#### Final Judgment:

Response A: <resp\_a\_judge>Correct/Incorrect</resp\_a\_judge> Response B: <resp\_b\_judge>Correct/Incorrect</resp\_b\_judge>

**Question:** <question> {question} </question> Response A: <response\_a> {response\_a} </response\_a> Response B: <response\_b> {response\_b} </response\_b>
