Abstract

Recent large language models (LLMs) have advanced table understanding capabilities but rely on converting tables into text sequences. While multimodal large language models (MLLMs) enable direct visual processing, they face limitations in handling scientific tables due to fixed input image resolutions and insufficient numerical reasoning capabilities. We present a comprehensive framework for multimodal scientific table understanding and reasoning with dynamic input image resolutions. Our framework consists of three key components: (1) MMSci-Pre, a domain-specific table structure learning dataset of 52K scientific table structure recognition samples, (2) MMSci-Ins, an instruction tuning dataset with 12K samples across three table-based tasks, and (3) MMSci-Eval, a benchmark with 3,114 testing samples specifically designed to evaluate numerical reasoning capabilities. Extensive experiments demonstrate that our domain-specific approach with 52K scientific table images achieves superior performance compared to 150K generaldomain tables, highlighting the importance of data quality over quantity. Our proposed tablebased MLLMs with dynamic input resolutions show significant improvements in both general table understanding and numerical reasoning capabilities, with strong generalisation to held-out datasets. Our code and data are publicly available at [https://github.com/](https://github.com/Bernard-Yang/MMSci_Table) [Bernard-Yang/MMSci_Table](https://github.com/Bernard-Yang/MMSci_Table).

1 Introduction

Tables serve as a fundamental tool for organising structured information across diverse domains. Recent studies have shown the potential of leveraging large language models (LLMs) to automatically understand and process tabular data, which has emerged as a critical research direction with applications such as Table Question Answering

(TQA) [\(Pasupat and Liang,](#page-9-0) [2015\)](#page-9-0), Table Fact Verification (TFV) [\(Chen et al.,](#page-8-0) [2020a\)](#page-8-0), and Table-to-Text Generation (T2T) [\(Moosavi et al.,](#page-9-1) [2021\)](#page-9-1).

However, current table-oriented LLMs [\(Zhang](#page-10-0) [et al.,](#page-10-0) [2023;](#page-10-0) [Li et al.,](#page-9-2) [2023b\)](#page-9-2) face inherent limitations as they require converting tables into sequential text formats (i.e., Markdown and HTML strings), potentially losing crucial structural and positional information. While table-based multimodal large language models (MLLMs) have addressed this by enabling direct processing of table images, several critical limitations persist: (1) fixed input image resolutions that constrain practical applicability, (2) limited capability in processing scientific tables that contain significant numerical values, and (3) insufficient numerical reasoning abilities for scientific domain tasks. These limitations are particularly significant in scientific domains, where tables frequently incorporate complex numerical relationships, statistical analyses, and domain-specific notations. While current MLLMs have demonstrated efficacy with general-domain tables (e.g., tables from Wikipedia or reports), they exhibit substantial performance degradation when confronted with scientific tables that mostly contains numerical values.Processing such tables effectively requires not only visual understanding to capture structural elements but also advanced numerical reasoning capabilities to interpret and analyse complex numerical relationships, statistical significance, and experimental results. Current MLLMs, however, lack the specific architectural designs and training paradigms necessary to handle these sophisticated scientific table understanding requirements.

To address these challenges, we introduce a comprehensive framework for multimodal scientific table understanding and reasoning that supports dynamic input image resolutions. We first conduct a systematic analysis of table source effectiveness by developing MMSci-Pre, a carefully curated table structure recognition dataset con-

taining 52K samples based on tables from scientific papers. Through extensive experiments, we demonstrate that MLLMs trained on these scientific domain-specific table images significantly outperform those trained on 150K general-domain tables, highlighting the importance of data quality over quantity in table understanding tasks. We conduct a systematic analysis of table source effectiveness through MMSci-Pre, a carefully curated dataset containing 52K structure recognition samples derived from scientific papers. Our experimental results demonstrate that MLLMs trained on these domain-specific table images significantly outperform those trained on 150K general-domain tables, establishing the importance of data quality over quantity in table understanding tasks.

Building upon this foundation, we then create MMSci-Ins, an instruction tuning dataset comprising 12K samples with explicit intermediate reasoning steps across three fundamental tasks: TQA, TFV, and T2T. Each sample includes detailed step-by-step reasoning processes to develop models' mathematical reasoning and scientific analysis capabilities. To overcome the limitations of fixed-resolution approaches in existing table MLLMs [\(Lee et al.,](#page-9-3) [2023;](#page-9-3) [Alonso et al.,](#page-8-1) [2024;](#page-8-1) [Zheng et al.,](#page-10-1) [2024\)](#page-10-1), we implement our framework with dynamic input image resolution capabilities on two distinct model architectures (Qwen2-VL-7B-Instruct and LLaVA-NeXT-7B). Experimental results demonstrate consistent performance improvements across both general table understanding and specialised numerical reasoning tasks.

To enable comprehensive evaluation, we establish MMSci-Eval, a benchmark with 3,114 testing samples requiring numerical reasoning capabilities. The benchmark provides rigorous assessment of models' performance across TQA, TFV, and T2T tasks. Our extensive experiments demonstrate that MMSci achieves superior performance with remarkable data efficiency. Specifically, our 52K scientific table images prove more effective than 150K general-domain table images for both general understanding and numerical reasoning tasks. This efficiency highlights the value of domain-specific, high-quality data in developing robust table understanding capabilities.

Our contributions are summarised as follows:

• We introduce MMSci, a comprehensive framework consisting of three key components: (1) MMSci-Pre, consists of 52K table image-toHTML table structure recognition samples; (2) MMSci-Ins, an instruction tuning dataset of 12K samples with reasoning steps; and (3) MMSci-Eval, a benchmark with 3,114 samples for numerical reasoning capabilities assessment across TQA, TFV, and T2T tasks.

- We develop a comprehensive table-based MLLM framework that achieves strong performance on three table-based numerical reasoning tasks while demonstrating robust generalisation to held-out datasets.
- We implement dynamic input resolution capabilities across different model architectures, validating the effectiveness of our approach through consistent performance gains on both Qwen2-VL-7B-Instruct and LLaVA-NeXT-7B.

2 Related Work

2.1 Table Understanding Models

Early table-based models pre-train general language models with large-scale table corpus [\(Liu](#page-9-4) [et al.,](#page-9-4) [2022;](#page-9-4) [Chen et al.,](#page-8-2) [2023\)](#page-8-2) but they can only support limited types of tables and tasks. Table understanding capabilities have been enhanced through prompt engineering [\(Chen,](#page-8-3) [2023;](#page-8-3) [Sui et al.,](#page-10-2) [2023\)](#page-10-2), instruction tuning [\(Zhang et al.,](#page-10-0) [2023;](#page-10-0) [Li](#page-9-2) [et al.,](#page-9-2) [2023b;](#page-9-2) [Yang et al.,](#page-10-3) [2024b\)](#page-10-3) and external tools [\(Lu et al.,](#page-9-5) [2023a;](#page-9-5) [Li et al.,](#page-9-6) [2023a\)](#page-9-6). However, these approaches require converting tables into text formats, limiting their applications.

Recently, MLLMs have emerged as a promising direction for table understanding. TableGPT2 [\(Su](#page-10-4) [et al.,](#page-10-4) [2024a\)](#page-10-4) features a novel table encoder to handle schema and cell-level information. Pix2Struct [\(Lee et al.,](#page-9-3) [2023\)](#page-9-3) introduces a unified image-to-text model pretrained on web page screenshots with HTML supervision. PixT3 [\(Alonso](#page-8-1) [et al.,](#page-8-1) [2024\)](#page-8-1) takes table-to-text tasks as table visual recognition tasks and generates texts. Table-LLaVA [\(Zheng et al.,](#page-10-1) [2024\)](#page-10-1) introduces a novel multimodal table understanding approach that directly processes table images. However, these approaches do not focus on datasets requiring sophisticated numerical reasoning capabilities.

2.2 Table-based Reasoning and Datasets

Table-based reasoning requires reasoning over both free-form natural language queries and structured

Figure 1: Overview of the proposed framework, which consists of four key stages: (1) Table Image Generation; (2) MMSci Dataset Construction; (3) Table Structure Learning; and (4) Visual Instruction Tuning.

tables. Early works either rely on executable languages (*e.g.*, SQL) [\(Yin et al.,](#page-10-5) [2016;](#page-10-5) [Yu et al.,](#page-10-6) [2018\)](#page-10-6) to capture logical structure in statements. TAPAS [\(Herzig et al.,](#page-8-4) [2020\)](#page-8-4), and DATER [\(Ye et al.,](#page-10-7) [2023\)](#page-10-7) encode sentence-table pairs and transform table-based reasoning into question-answering or inference tasks. Existing datasets primarily focus on specific domains like Wikipedia and finance. HybridQA [\(Chen et al.,](#page-8-5) [2020b\)](#page-8-5) from Wikipedia emphasises span lookup, while TAT-QA [\(Zhu et al.,](#page-10-8) [2021\)](#page-10-8), FinQA [\(Chen et al.,](#page-8-6) [2021\)](#page-8-6), and DocMath-Eval [\(Zhao et al.,](#page-10-9) [2024\)](#page-10-9) address numerical reasoning in the financial domain. However, these datasets have relatively limited reasoning types, significantly differing from real-world scientific table understanding that require numerical computation reasoning [\(Wu et al.,](#page-10-10) [2024\)](#page-10-10). To address this gap, we propose our dataset that combines multiple reasoning types to enhance model performance on complex scientific table understanding tasks.

3 Construction of MMSci Dataset

As shown in Figure [1,](#page-2-0) our framework process consists of four key stages: (1) Table Image Generation: converting SciGen dataset tables into highquality HTML and image formats; (2) MMSci Dataset Construction: employing GPT-4o with selfconsistency voting and human verification to generate high-quality samples; (3) Table Structure Learning: training MLLMs to generate HTML representations from table images; and (4) Visual Instruction Tuning: fine-tuning MLLMs on instructionfollowing data across TQA, TFV, and T2T tasks.

3.1 Data Collection

To construct our dataset, we focus on scientific tables that contain significant numerical values and complex reasoning requirements. We collect raw tabular data from the SciGen dataset [\(Moosavi](#page-9-1) [et al.,](#page-9-1) [2021\)](#page-9-1), which provides pairs of scientific tables and their corresponding descriptions across computer science research domains. A large number of these descriptions require arithmetic reasoning (e.g., argMax, argMin, comparison, subtraction) over table values, indicating the natural presence of numerical reasoning in scientific table descriptions. We transform the original textual tables into high-quality HTML format and then render them into table images while preserving their structural integrity. This process ensures that the visual representation maintains the complex layouts and relationships present in the original scientific tables. Finally, we collect 52K image-to-HTML pairs based on tables from the training set and development set of the SciGen dataset.

3.2 Table Structure Learning

Existing table-based MLLMs [\(Lee et al.,](#page-9-3) [2023;](#page-9-3) [Alonso et al.,](#page-8-1) [2024;](#page-8-1) [Zheng et al.,](#page-10-1) [2024\)](#page-10-1) demonstrate that generating textual table representations given the table image is crucial for aligning table structure and text information within the table image. Therefore, we create 52K instructionfollowing image-to-HTML samples based on the tables from the training set of SciGen dataset via the Imgkit^{[1](#page-3-0)} python package. The resulting pretraining data contains 52K table image-to-HTML examples, which is denoted as MMSci-Pre dataset.

3.3 Numerical Reasoning Augmentation

For the construction of instruction dataset MMSci-Ins and MMSci-Eval, we select 12,000 tables from the training set and 1,038 from the testing set of SciGen dataset to create MMSci-Ins and MMSci-Eval datasets, respectively. For each table, we employ GPT-4o [\(OpenAI,](#page-9-7) [2024\)](#page-9-7) to generate taskspecific content by feeding the table image and its corresponding descriptions in SciGen dataset. In TQA tasks, we generate questions paired with corresponding reasoning steps and answers. For TFV tasks, we create claims along with supporting reasoning steps and verification results. The labels of claim including three types: supported, refuted, and not enough information, which is consistent with the existing TFV datasets [\(Lu et al.,](#page-9-8) [2023c\)](#page-9-8). Additionally, we augment the existing table-to-text pairs in SciGen with detailed reasoning steps for T2T tasks.

To ensure the quality and consistency of the generated content, we implement a selfconsistency Chain-of-Thought (CoT) reasoning mechanism [\(Wang et al.,](#page-10-11) [2022\)](#page-10-11). For each task, we generate multiple reasoning paths and employ a voting mechanism to determine the final output. To validate the quality of these generated samples, we employ a two-stage verification process: first using GPT-4o to assess the consistency between reasoning steps and outputs, then manually assess 40% of the samples to ensure high quality. The identified false samples are regenerated using GPT-4o to maintain dataset quality.

Through this rigorous data construction process, we create the MMSci-Ins dataset comprising 12K instruction-tuning samples based on the training set of SciGen dataset, and the MMSci-Eval benchmark with 3,114 testing examples based on the testing set of SciGen dataset. Each sample includes detailed step-by-step reasoning processes, enabling models to learn both the final outputs and the logical progression needed to arrive at those conclusions. The dataset maintains a balanced distribution across the three tasks, where each table is paired with one TQA, one TFV, and one T2T task, ensuring comprehensive coverage of different reasoning requirements in scientific table understanding.

Table 1: The reasoning types, descriptions, and proportion in our MMSci-Ins and MMSci-Eval dataset. More details are provided in Appendix [A.1](#page-11-0)

4 Experiments

4.1 Model Training

To demonstrate the effectiveness of MMSci dataset, we train two series of MLLM following the architecture of Qwen2-VL-7B-Instruct [\(Wang et al.,](#page-10-12) [2024\)](#page-10-12) and LLaVA-NeXT-7B [\(Li et al.,](#page-9-9) [2024\)](#page-9-9).

Model Architectures. Both models follow a threecomponent design: Qwen2-VL-7B-Instruct consists of a Vision Transformer (ViT) [\(Dosovitskiy,](#page-8-7) [2020\)](#page-8-7) as the vision tower, a MLP as the visionlanguage connector, and a Qwen2 [\(Yang et al.,](#page-10-13) [2024a\)](#page-10-13) as the language model. LLaVA-NeXT-7B uses a pre-trained CLIP model [\(Radford et al.,](#page-9-10) [2021\)](#page-9-10) as the visual encoder, a MLP connector, and a Vicuna-7B model [\(Chiang et al.,](#page-8-8) [2023\)](#page-8-8) as the backbone. In both architectures, the vision encoder processes images into visual features, which are projected into the LLM's word embedding space via the MLP connector.

We divide the training into two stages:

Table Structure Learning. We use both MMSci-Pre and MMTab-Pre [\(Zheng et al.,](#page-10-1) [2024\)](#page-10-1) corpus (202K table image-to-HTML pairs) to align visual features with textual representations in different experimental settings as shown in Table [2.](#page-4-0) Models learn to generate HTML table representations, developing table structure perception capabilities. For LLaVA-NeXT-7B, only the MLP connector parameters are updated during this stage.

Visual Instruction Tuning. Using 12K instructionfollowing samples from MMSci-Ins, we fine-tune the MLLMs while keeping visual encoders frozen. Only the MLP projection layer and LLM weights are updated, focusing on developing instructionfollowing numerical reasoning capabilities across TQA, TFV, and T2T tasks.

Notably, both models support dynamic input

resolutions, addressing a key limitation of existing table MLLMs [\(Lee et al.,](#page-9-3) [2023;](#page-9-3) [Alonso et al.,](#page-8-1) [2024;](#page-8-1) [Zheng et al.,](#page-10-1) [2024\)](#page-10-1) that require fixed-size inputs (e.g., 336×336). Qwen2-VL achieves this through 2D-RoPE [\(Su et al.,](#page-10-15) [2024b\)](#page-10-15) to capture two-dimensional positional information of images, while LLaVA-NeXT employs a simpler approach of splitting images into grids and encoding them independently.

4.2 Experimental Settings

Baselines. We evaluate several state-of-the-art MLLMs as our baselines, including GPT-4V [\(Ope](#page-9-11)[nAI,](#page-9-11) [2023\)](#page-9-11), InternVL-2-76B [\(Chen et al.,](#page-8-9) [2024\)](#page-8-9), LLaVA-NeXT series (72B/34B/13B/7B) [\(Li et al.,](#page-9-9) [2024\)](#page-9-9), Qwen-2-VL-Instruct series (72B/7B) [\(Wang](#page-10-12) [et al.,](#page-10-12) [2024\)](#page-10-12), Table-LLaVA series (13B/7B) [\(Zheng](#page-10-1) [et al.,](#page-10-1) [2024\)](#page-10-1), Pixtral-12B [\(Agrawal et al.,](#page-8-10) [2024\)](#page-8-10), Llama-3.2-11B-Vision-Ins. [\(Meta,](#page-9-12) [2024\)](#page-9-12), MiniCPM-V-2.6-8B [\(Yao et al.,](#page-10-14) [2024\)](#page-10-14), and InternVL-2-8B [\(Chen et al.,](#page-8-9) [2024\)](#page-8-9).

Datasets and Metrics. The held-out datasets in Table [3](#page-5-0) are from MMTab-Eval benchmark [\(Zheng](#page-10-1) [et al.,](#page-10-1) [2024\)](#page-10-1). TQA contains TABMWP [\(Lu](#page-9-13) [et al.,](#page-9-13) [2023b\)](#page-9-13), WTQ [\(Pasupat and Liang,](#page-9-0) [2015\)](#page-9-0), HiTab [\(Cheng et al.,](#page-8-11) [2022\)](#page-8-11), TAT-QA [\(Zhu et al.,](#page-10-8) [2021\)](#page-10-8), and FeTaQA [\(Nan et al.,](#page-9-14) [2022\)](#page-9-14), where TABMWP and TAT-QA specifically focus on tabular numerical reasoning. TFV contains TabFact [\(Chen et al.,](#page-8-0) [2020a\)](#page-8-0) and InfoTabs [\(Gupta et al.,](#page-8-12) [2020\)](#page-8-12), while Table-to-Text (T2T) generation uses HiTab_T2T [\(Cheng et al.,](#page-8-11) [2022\)](#page-8-11), Rotowire [\(Wise](#page-10-16)[man et al.,](#page-10-16) [2017\)](#page-10-16), and WikiBIO [\(Lebret et al.,](#page-9-15) [2016\)](#page-9-15). While these datasets contain tables from Wikipedia, financial reports, and government documents, our MMSci datasets primarily feature scientific tables with numerical values from research papers. We use accuracy and BLEU [\(Papineni et al.,](#page-9-16) [2002\)](#page-9-16) for TQA, TFV, and T2T benchmarks.

5 Results and Analysis

5.1 Performance on Numerical Reasoning **Datasets**

The experimental results demonstrate the effectiveness of our proposed approach across various multimodal table understanding tasks. As shown in Table 2, we compare our method with state-of-theart baselines on both MMSci benchmarks (TQA, TFV, T2T) and held-out datasets (TABMWP, TAT-QA). Among the baseline models, GPT-4V [\(Ope](#page-9-11)[nAI,](#page-9-11) [2023\)](#page-9-11) achieves superior performance across all tasks, establishing strong benchmarks with 53.13% accuracy on TQA, 78.01% on TFV, and notably strong generalisation ability on held-out numerical reasoning datasets. Large-scale models like InternVL-2-76B [\(Chen et al.,](#page-8-9) [2024\)](#page-8-9) and Qwen-2-VL-72B [\(Wang et al.,](#page-10-12) [2024\)](#page-10-12) also demon-

Table 3: Performance comparison on MMTab held-out datasets. Best results are in bold, second best are underlined.

strate competitive performance but show relatively weaker generalisation to held-out numerical reasoning datasets.

With LLaVA-NeXT-7B as the foundation model, we observe that MMSci-Pre (52k) demonstrates higher performance (17.72% on TQA, 57.12% on TFV) compared to MMTab-Pre (150k) (15.79% on TQA, 56.16% on TFV). The combination of both pre-training strategies (MM-Pre 202k) further improves performance to 23.02% on TQA and 58.57% on TFV. Notably, our approach shows strong generalisation ability on held-out datasets, achieving 49.72% on TABMWP with MM-Pre $(202k) + MMSci-Ins.$

With Qwen2-VL-7B-Ins. as the foundation model, we observe significantly stronger performance across all settings. MMSci-Pre (52k) + MMSci-Ins achieves comparable or better performance (41.13% on TQA, 72.92% on TFV) compared to MMTab-Pre (150k) + MMSci-Ins (40.75% on TQA, 72.73% on TFV), despite using only one-third of the pre-training data. The MM-Pre (202k) + MMSci-Ins variant achieves the best performance with 42.10% accuracy on TQA and 73.98% on TFV, while also demonstrating strong generalisation ability on held-out numerical reasoning datasets (49.96% on TABMWP and 20.85% on TAT-QA).

These results empirically demonstrate that our proposed MMSci-Pre strategy with 52K scientific domain-specific data is more effective than MMTab-Pre with 150K general-domain data, highlighting the importance of data quality over quantity. Furthermore, Qwen2-VL-7B-Instruct consistently outperforms LLaVA-NeXT-7B across all ex-

Table 4: Ablation study results for reasoning steps on MMSci-Eval and held-out datasets.

perimental settings, suggesting its stronger capability in table understanding and numerical reasoning tasks. Most importantly, our approach shows strong generalisation to held-out datasets with different table formats and reasoning requirements, demonstrating enhanced general ability in multimodal table understanding and reasoning.

5.2 Performance on Held-out MMTab Benchmarks

The experimental results demonstrate the effectiveness of our proposed approach across various table understanding tasks. As shown in Table [3,](#page-5-0) we evaluate our method against state-of-the-art baselines on MMTab held-out datasets across three primary tasks: TQA, TFV, T2T.

Among the baseline models, GPT-4V [\(Ope](#page-9-11)[nAI,](#page-9-11) [2023\)](#page-9-11) show strong benchmarks across all tasks, achieving 35.91% average accuracy on TQA, 55.55% on TFV, and 3.05 BLEU on T2T. Table-LLaVA models, which are specifically trained on

Figure 2: Performance scaling with increasing instruction tuning data size on three MMSci tasks.

MMTab-Ins dataset, demonstrate competitive performance. Notably, Table-LLaVA-13B achieves strong results on TFV (65.96% average accuracy) and T2T (9.63 BLEU), while Table-LLaVA-7B shows robust performance on TABMWP (57.78%).

With LLaVA-NeXT-7B as the foundation model, we observe that MMSci-Pre (52k), despite not being trained on MMTab-Ins dataset [\(Zheng et al.,](#page-10-1) [2024\)](#page-10-1), demonstrates promising generalisation ability. The MMSci-Pre (52k) + MMSci-Ins variant achieves 3.80% average accuracy on TQA and 30.57% on TFV with only scientific domain data. The combination of both pre-training strategies (MM-Pre 202k) further improves performance across all metrics, reaching 5.27% on TQA and 33.63% on TFV. As for Qwen2-VL-7B-Instruct as the foundation model, we observe significantly stronger generalisation capability. MMSci-Pre $(52k)$ + MMSci-Ins variant achieves 21.15% average accuracy on TQA and 41.63% on TFV, demonstrating strong zero-shot transfer to MMTab benchmark despite using only scientific domain pretraining data. This performance is particularly impressive when compared to MMTab-Pre (150k) + MMSci-Ins variant (20.35% on TQA, 43.28% on TFV), which uses three times more image-to-HTML data. Even without any pre-training (w/o MM-Pre), our approach achieves competitive results (20.94% on TQA, 39.23% on TFV), highlighting the effectiveness of our instruction tuning strategy.

These results empirically demonstrate three key insights: First, our MMSci-Pre strategy with 52K scientific domain-specific data achieves comparable or better performance than MMTab-Pre with 150K general-domain data, highlighting the importance of domain-specific pre-training. Second, even without MMTab pre-training data, our approach demonstrates strong generalisation ability, particularly evident in the performance of MMSci-Pre (52k) and w/o MM-Pre settings. Finally, Qwen2-VL-7B-Ins. shows superior generalisation capability compared to LLaVA-NeXT-7B, suggesting its stronger potential for multimodal table understanding tasks.

5.3 Ablation Study on Reasoning Steps

We conduct ablation studies to evaluate the effectiveness of reasoning steps across different experiment configurations, as shown in Table [4.](#page-5-1) Qwen2- VL-7B-Instruct demonstrates superior performance across all configurations. Notably, even without reasoning steps, the model with MMSci-Pre (52k) achieves better results than MMTab-Pre (150k), highlighting the importance of domain-specific table structure learning over data quantity. Adding reasoning steps consistently improves performance across all metrics, with the model reaching its peak performance under the MM-Pre (202k) configuration. Similar trends are observed in LLaVA-NeXT-7B, though with lower absolute performance. These patterns extend to held-out datasets, where both models show strong generalization capabilities with reasoning steps, especially on numerical reasoning tasks like TABMWP and TAT-QA. The results demonstrate that a smaller amount of domain-specific table structure learning data, combined with explicit reasoning steps, can be more effective than larger-scale general domain table structure learning.

5.4 Impact of Training Data Size

As shown in Figure [2,](#page-6-0) we compare performance of MM-Pre (202k) + MMSci-Ins experiment setting across three MMSci tasks (TQA, TFV, T2T) with instruction tuning data size increasing from 3K to 12K samples. The findings demonstrate consistent advantages of incorporating reasoning steps across all data scales. Models trained with reasoning steps maintain substantial performance advantages across all tasks (7-8% for TQA, 8-10% for TFV, 0.3-0.4 BLEU for T2T). While both vari-

Table 5: Kernel alignment analysis. The representation for each sample is the averaged token embeddings. The best two values are shown in bold and underlined.

ants benefit from increased training data, models with reasoning steps show stronger scaling behavior, particularly evident in TQA and TFV tasks. The persistent performance gap across all data sizes suggests that reasoning steps provide fundamental improvements in model learning that cannot be simply achieved through increased training data alone.

5.5 Representational Alignment Analysis

In this section, we conduct an in-depth analysis to assess the language-vision alignment from the perspective of the representation space. This analysis aims to provide further insights into the observed variations in model performance, particularly in the context of scientific multimodal table understanding and reasoning tasks.

Preliminaries. We formalise MLLMs within the framework of an *unembedding-embedding* architecture. In this framework, the unembedding stage is responsible for learning transformations between observations (e.g., text, vision) and latent spaces through encoders, while the embedding stage captures the complex interactions among latent variables within the latent space of LLMs' hidden layers. Each stage serves distinct functions and yields representations with different properties [\(Park et al.,](#page-9-17) [2024\)](#page-9-17). Consequently, by focusing on each stage independently, we can have a systematical evaluation of model behaviours in representation spaces. To assess the representational alignment between vision-language modalities at each stage, we next measure the geometrical similarity between them

via the *kernel*.

Kernels, characterising the distance metrics between points in a representation space, are commonly used to assess vector space [\(Huh et al.,](#page-9-18) [2024\)](#page-9-18). Typically, the more similarity between two kernels derived from different spaces indicates a higher degree of alignment between those spaces. This similarity can be quantified via *kernelalignment metrics*, such as Centered Kernel Distance (CKA) [\(Kornblith et al.,](#page-9-19) [2019\)](#page-9-19). For more information about kernel-alignment metrics used in the experiment, we refer to [\(Huh et al.,](#page-9-18) [2024\)](#page-9-18) for a deep understanding.

Quantitative evaluation. For the unembedding stage, we specifically choose two language-vision datasets: ImageNet [\(Deng et al.,](#page-8-13) [2009\)](#page-8-13) and Wikipedia Caption (WIT) [\(Srinivasan et al.,](#page-9-20) [2021\)](#page-9-20). These datasets offer varying levels of fine granularity in language-vision alignment, enabling a comprehensive assessment of representational performance. As illustrated in Table [5,](#page-7-0) we can observe that the Qwen2-VL-7B-Instruct can generally outperform other baselines on both datasets, indicating it has better fine-grained alignment between language and vision, potentially resulting in better vision-language consistency as shown in Table [6.](#page-12-0) In the embedding stage, we evaluate alignment on the MMSci T2T task. Since some models do not support single-modality input, we utilise a reference language model (e.g., open-llama- $7B²$ $7B²$ $7B²$) as the text encoder and MLLMs as the image encoder

² [https://huggingface.co/openlm-research/open_](https://huggingface.co/openlm-research/open_llama_7b) [llama_7b](https://huggingface.co/openlm-research/open_llama_7b)

with prompt *"please describe the table"*. Alignment is measured based on the output embedding from the last hidden layer. As shown in Table [5,](#page-7-0) Qwen2-VL-7B-Instruct outperforms the other models, demonstrating its superior language-vision alignment capability.

6 Conclusion

In this paper, we introduce a comprehensive framework for multimodal scientific table understanding and reasoning with dynamic input resolutions, consisting of MMSci-Pre, MMSci-Ins, and MMSci-Eval components. Our experiments demonstrate that domain-specific table structure learning with 52K scientific table images outperforms 150K general-domain tables, highlighting the importance of data quality over quantity in table understanding tasks. Experimental results validate our framework's effectiveness across different model architectures, showing consistent improvements in both general table understanding and numerical reasoning capabilities, with strong generalisation to heldout datasets.

A Details about MMSci

A.1 Datasets Statistics

Table [1](#page-3-1) presents the distribution of reasoning types in our MMSci-Eval dataset. The most common type is addition (21.1%), followed by subtraction (15.3%) and max/min operations (15.1%). Division and comparison operations also appear frequently (14.2% and 13.7% respectively). More complex operations like ranking (9.6%) and look-up (8.9%) occur less frequently, while domain knowledge calculations are rare (1.5%).

The average number of reasoning steps varies significantly across types, with subtraction requiring the most steps (4.1) and look-up operations requiring the fewest (1.5). This variation reflects the inherent complexity of different mathematical operations and their application to tabular data. Notably, even seemingly simple operations like addition require multiple steps (2.8) on average, indicating the complexity of reasoning with tabular scientific data.

A.2 Prompt for Generating Data

The prompt for MMSci-Ins and MMSci-Pre data generation is shown in Table [7.](#page-13-0)

B Experimental Settings

Implementation Details. Both models follow a three-component design. Qwen2-VL-7B-Instruct consists of a Vision Transformer (ViT) [\(Dosovit](#page-8-7)[skiy,](#page-8-7) [2020\)](#page-8-7) as the vision tower, a MLP as the visionlanguage connector, and Qwen2 [\(Wang et al.,](#page-10-12) [2024\)](#page-10-12) as the language model. LLaVA-NeXT-7B uses a pre-trained CLIP model [\(Radford et al.,](#page-9-10) [2021\)](#page-9-10) as the visual encoder, a MLP connector, and Vicuna-7B [\(Chiang et al.,](#page-8-8) [2023\)](#page-8-8) as the backbone. In both architectures, the vision encoder processes images into visual features, which are projected into the LLM's word embedding space via the MLP connector.

Training Details. All experiments are conducted on 4×A100 80GB GPUs using LoRA with rank 64 and sequence length 4096. For table structure learning, LLaVA-NeXT-7B requires 15 hours for MMTab-Pre (150k), 3 hours for MMSci-Pre (52k), and 20 hours for combined training (one epoch). Qwen2-VL-7B takes 15 hours, 8 hours, and 19 hours respectively. The instruction tuning stage requires approximately 1 hour for 4 epochs with 12k samples for both models.

C More Experimental Results and Analysis

C.1 Vision-Language Consistency Analysis

We evaluate the cross-modal consistency of different MLLMs by comparing their performance when processing table information through different modalities. For each model, we test with both table images (image modality) and their textual representations (text modality), measuring both task performance (Acc.) and cross-modal consistency (Consis.).

Qwen2-VL-7B-Instruct demonstrates superior cross-modal alignment, achieving the highest consistency scores on both TQA (60.40%) and TFV (72.48%) tasks. Notably, it maintains strong performance across both modalities, with image-based accuracy (TQA: 39.11%, TFV: 52.79%) consistently outperforming text-based results (TQA: 21.65%, TFV: 50.10%). This suggests robust integration of visual and textual understanding capabilities.

Other models show varying degrees of modality gap. MiniCPM-V-2.6-8B and InternVL-2-8B achieve moderate consistency (48.78% and 50.89% on TQA), while models like LLaVA-NeXT-7B and Pixtral-12B show significant disparities between modalities, resulting in lower consistency scores. These results highlight the challenge of maintaining consistent reasoning capabilities across different input modalities in table understanding tasks.

D Dataset Examples and Case Study

D.1 Dataset Examples

The training examples of MMSci-Pre Dataset are shown in Figure [3.](#page-12-1) The examples of MMSci-Eval are shown Figure [5.](#page-14-0)

D.2 Case Study

The case study of TQA and TFV tasks are shown in Figure [5](#page-14-0) and Figure [6,](#page-15-0) respectively

Table 6: Vision-language consistency evaluation across different MLLMs. Consistency scores measure the percentage of identical responses between modalities, indicating the model's cross-modal alignment.

Figure 3: MMSci-Pre Dataset example

The prompt for Generating data

You are given a table image and a description: {description}.

1.For the Table to Text (T2T) task, come up with a one to two sentence length succinct multi-hop reasoning step of the description.

Write your results as 'T2T Reasoning:' and then the succinct reasoning step.

2.For the Table Question Answering (TQA) task, come up with a question and answer with multi-hop reasoning step.

The question and answer must be based on the table image and description.

Write your results as 'TOA Question:' and then the question and 'TOA Reasoning:' and then the reasoning step and 'TQA Answer:' and then the answer.

When generating 'TQA Question:', make sure it is a single question that requires reasoning based on the table.

When generating 'TQA Answer:', provide the final answer in the JSON structure, using the format "answer": "<YOUR ANSWER>"

Make sure the answer only contains one entity, such as 'So, the answer is "answer": "23".'

3.For the Table Fact Checking (TFV) task, come up with a statement and answer with multi-hop reasoning step.

The statement and answer must be based on the table image and description. The table 'supports' or 'refutes' the statement. The statement should be considered 'not enough info' if it may or may not be true. Write your results as 'TFV Statement:' and then the statement and 'TFV Reasoning:' and then the reasoning step and 'TFV Answer:' and then the answer.

Make sure the answer only contains one entity, such as 'Thus, the answer is "answer": "supports".'

When generating 'TFV Answer:', provide the final answer in the JSON structure, using the format "answer": "<YOUR ANSWER>"

Fill the result into JSON format without any other words:

"T2T Reasoning": "<YOUR T2T REASONING>", "TQA Question": "<YOUR TQA QUESTION>", "TQA Reasoning": "<YOUR TQA REASONING>", "TQA Answer": "<YOUR TQA ANSWER>", "TFV Statement": "<YOUR TFV STATEMENT>", "TFV Reasoning": "<YOUR TFV REASONING>", "TFV Answer": "<YOUR TFV ANSWER>" Examples:

{TQA Examples} {TFV Examples} {T2T Examples}

Table 7: The prompts for generating the questions, reasoning steps, and answers or claims of MMSci-Ins and MMSci-Eval datasets.

Task	Table Image								Input: Task, Output format, Task-related input	Output: Reasoning, Answer or description
Table Question Answer	Model		Target Transfer Transfer Transfer Baseline tuned Gain Corpus BERT	Filler	Role	Acc. $(\%)$ Acc. $(\%)$	Fine-		Refer to the provided table image and work through the question step by step. Output the	By comparing the gain percentages for the RTE target corpus, HUBERT
Table Fact Verification	BERT BERT BERT BERT BERT HUBERT Transformer HUBERT (Transformer HUBERT (Transformer HUBERT (Transformer HUBERT Transformer)SST	ONLI QQP RTE SNLI SST QNLI QQP RTE SNLI	True True True True True True False True True True	True False True False False	False True True True True	91.60 91.45 71.12 90.45 93.23 90.56 90.81 61.73 90.66 91.28	(%) 91.27 $91.16 \frac{1}{0.60}$ $91.42 \frac{1}{0.61}$ 74.01	$\overline{0.33}$ $91.12\begin{array}{ c } 0.33 \end{array}$ 73.65 2.53 $90.69\begin{array}{ c c }\n & 0.24\n\end{array}$ 92.78 _{0.45} 12.28 $91.36\begin{bmatrix} 1 \\ 0.70 \end{bmatrix}$ $92.43 \frac{1}{1.15}$	final answer as JSON in the format {'answer': ' <your answer="">'}. Question: 'Which model shows the highest gain in accuracy for the RTE target corpus Using the given table image, determine if the claim is 'supports' or 'refutes'. If the table does not provide sufficient information, the answer should be 'not enough info'. Output the final answer as JSON in the format {'answer': '<your answer="">'}. BERT shows a gain in accuracy for the ONLI target corpus.</your></your>	(Transformer) shows a gain of +12.28%, which is higher than BERT's gain of $+2.53\%$.", So, the answer is {"answer": "HUBERT (Transformer)"}. The table shows that BERT has a gain of - 0.33% for the QNLI target corpus, indicating an decrease in accuracy. Thus, the answer is {\"answer\": \"refutes\"}.
Table to Text Generation	Table 3: Transfer learning results for GLUE tasks. The source corpus is MNLI. Baseline accuracy is when Transfer BERT, Filler, and Role are all False, equivalent to no transfer. Fine-tuned accuracy is the best accuracy among all possible transfer options.								You are provided with a table image with caption. Formulate a statement describing the table. Table Caption: 'Table 3: Transfer learning results for GLUE tasks. The source corpus is MNLI. Baseline accuracy is when Transfer BERT, Filler, and Role are all False, equivalent to no transfer. Fine-tuned accuracy is the best accuracy among all possible transfer options.	HUBERT (Transformer) shows substantial gains across all target corpora after transfer learning from MNLI, while BERT shows a drop in accuracy for QNLI, QQP, and SST. Table 3 summarizes the results for these transfer learning experiments when the source task is MNLL Gain shows the difference between Fine-tuned model's accuracy and Baseline's accuracy. For HUBERT (Transformer), we observe substantial gain across all 5 target corpora after transfer. However, for BERT we have a drop for QNLI, QQP, and SST.
