# HIGHER DIMENSIONAL TETER RINGS

TONY J. PUTHENPURAKAL

ABSTRACT. Let  $(A, \mathfrak{m})$  be a complete Cohen-Macaulay local ring. Assume  $A$  is not Gorenstein. We say  $A$  is a Teter ring if there exists a complete Gorenstein ring  $(B, \mathfrak{n})$  with dim  $B = \dim A$  and a surjective map  $B \to A$  with  $e(B) - e(A) = 1$  (here  $e(A)$  denotes multiplicity of A). We give an intrinsic characterization of Teter rings which are domains. We say a Teter ring is a strongly Teter ring if  $G(B) = \bigoplus_{i \geq 0} \mathfrak{n}^i / \mathfrak{n}^{i+1}$  is also a Gorenstein ring. We give an intrinsic characterizations of strongly Teter rings which are domains. If  $k$ is algebraically closed field of characteristic zero and  $R$  is a standard graded Cohen-Macaulay k-algebra of finite representation type (and not Gorenstein) then we show that  $\widehat{R_{\mathfrak{M}}}$  is a Teter ring (here  $\mathfrak{M}$  is the maximal homogeneous ideal of  $R$ ).

### 1. introduction

Let  $(A, \mathfrak{m})$  be an Artinian local ring. Note there exists an Artinian Gorenstein local ring B with a surjective map  $B \to A$ . Let  $\ell(A)$  denote length of A. The Gorenstein co-length of A is defined as

 $g(A) = min\{\ell(B) - \ell(A) | B$  is Gorenstein Artin local ring mapping onto A }.

We note that  $g(A) = 0$  if and only if A is Gorenstein. Observe that  $g(A) = 1$  if and only if A is not Gorenstein and  $A = B/\operatorname{soc}(B)$  for a Gorenstein Artin local ring B. W. Teter gives an intrinsic characterization for such rings in his paper [\[9\]](#page-10-0). In their paper [\[5\]](#page-10-1), C. Huneke and A. Vraciu refer to these rings as Teter's rings.

We generalize the definition of Teter rings to higher dimensions. Let  $(A, \mathfrak{m})$  be a local Cohen-Macaulay local ring of dimension  $d$ . We assume  $A$  is a quotient of a regular local ring T. Let  $e(A)$  denote the multiplicity of A. We note that there exists a Gorenstein local ring B mapping onto A with dim  $B = \dim A$ . Let  $U(A)$ denote the set of all Gorenstein local rings  $B$  which are quotients of  $T$ , mapping onto A with dim  $B = \dim A$ . Set

$$
g(A) = \min\{e(B) - e(A) \mid B \in U(A) \}.
$$

We note that  $g(A) = 0$  if and only if A is a Gorenstein local ring. If  $g(A) = 1$ then we call A to be a *Teter* ring. If  $B \in U(A)$  such that  $e(B) - e(A) = 1$  then we call B to be a *Teter Gorenstein approximation* of A. Note we are *not* asserting that  $B$  is uniquely determined by  $A$ .

In general giving an intrinsic characterization of Teter's ring seems to be difficult. However for domains we have

<sup>2020</sup> Mathematics Subject Classification. Primary 13H10 ; Secondary 13A30 .

Key words and phrases. Gorenstein rings, Finite Cohen–Macaulay type, canonical module, associated graded rings and modules.

<span id="page-1-1"></span>Theorem 1.1. *Let* (A, m) *be a Cohen-Macaulay local domain. Assume* A *is a quotient of a regular local ring* T. Assume A *is not Gorenstein. Let*  $\omega_A$  *denote the canonical module of* A*. The following assertions are equivalent:*

(i) A *is a Teter ring.*

(ii) *There exists a proper ideal* J of A with  $\omega_A \cong J$  and codim  $A/J \leq 1$ .

*Furthermore if* A *is a Teter-ring then the Teter Gorenstein approximation of* A *is unique (up to isomorphism).*

Also if  $(R, \mathfrak{m})$  is a local Noetherian ring then codim  $R = \mu(\mathfrak{m}) - \dim R$  (here  $\mu(\mathfrak{m})$  denotes the minimal number of generators of  $\mathfrak{m}$ ).

If  $(R, \mathfrak{n})$  is a Noetherian local ring then  $G(R) = \bigoplus_{i \geq 0} \mathfrak{n}^i / \mathfrak{n}^{i+1}$  is the associated graded ring of  $R$ . We say  $A$  is strongly Teter if  $A$  has a Teter Gorenstein approximation  $(B, \mathfrak{n})$  with  $G(B)$  Gorenstein. Being strongly Gorenstein is a very restricted property. We show

<span id="page-1-0"></span>Theorem 1.2. *Let* (A, m) *be a Cohen-Macaulay local ring. Assume* A *is a quotient of a regular local ring* T *. If* A *is strongly Teter then* G(A) *is Cohen-Macaulay.*

Theorem [1.2](#page-1-0) can be used to give examples of rings which are Teter but not strongly Teter, see [5.7.](#page-8-0) We give an intrinsic characterization of Cohen-Macaulay local domains which are strongly Teter.

<span id="page-1-2"></span>Theorem 1.3. *Let* (A, m) *be a Cohen-Macaulay local domain. Assume* A *is a quotient of a regular local ring* T *. Assume* A *is not Gorenstein. The following assertions are equivalent:*

- (i) A *is a strongly Teter ring.*
- (ii) A *satisfies the following properties.*
	- (a) G(A) *is Cohen-Macaulay.*
	- (b) *There exists a proper ideal* J of A with  $\omega_A \cong J$  and  $\text{codim } A/J \leq 1$ .
	- (c) *Consider the filtration*  $\mathcal{F} = \{J_n = J \cap \mathfrak{m}^n\}_{n \geq 0}$  *on J.* Then  $G_{\mathcal{F}}(J)$  *is isomorphic to the graded canonical module of* G(A) *(up to a shift).*

In [\[5\]](#page-10-1), the authors stated that rings of utmost countable representation type should be close to Gorenstein rings. We prove this for homogeneous rings of finite representation type. Recall that a graded algebra over a field has finite representation type if it has up to isomorphisms and shifts in the grading, only a finite number of indecomposable maximal Cohen-Macaulay modules.

<span id="page-1-3"></span>Theorem 1.4. *Let* k *be an algebraically closed field of characteristic zero. Let* R *be a standard Cohen-Macaulay* k*-algebra with maximal homogeneous ideal* M*. Assume* R *is NOT Gorenstein. Further assume* R *is of finite Cohen-Macaulay type. Let*  $A = \overline{R_{\mathfrak{M}}}$  be its completion with respect to  $\mathfrak{M}$ . Then A is a Teter ring.

We now describe in brief the contents of this paper. In section two we prove Theorem [1.1.](#page-1-1) In section three we give proof of Theorem [1.2.](#page-1-0) In section four we give a proof of Theorem [1.3.](#page-1-2) Finally in section five we give examples and prove Theorem [1.4.](#page-1-3)

# 2. Proof of Theorem [1.1](#page-1-1)

In this section we give a proof of Theorem [1.1.](#page-1-1) We first prove

*Proof of (i)*  $\implies$  *(ii).* Let dim A = d. As A is a Teter ring there exists a ddimensional Gorenstein local ring B mapping onto A with  $e(B) - e(A) = 1$ . We have an exact sequence

$$
0 \to M \xrightarrow{g} B \xrightarrow{f} A \to 0, \quad \text{where } e(M) = 1.
$$

We note that M is a MCM B-module with  $e(M) = 1$ . Dualizing the above exact sequence we obtain an exact sequence

$$
0 \to \omega_A \xrightarrow{f^\vee} B \xrightarrow{g^\vee} M^\vee \to 0.
$$

We note that  $M^{\vee}$  is a Cohen-Macaulay ring of dimension d. As  $e(M^{\vee}) = e(M) = 1$ , it follows that  $M^{\vee}$  is a regular local ring. Denote it by Q. Consider the map  $\omega_A \xrightarrow{f \circ f^{\vee}} A$  and let K be the kernel of this map. Set  $V = \omega_A/K$  and let  $i' : V \to A$ be the induced injection. We have the following commutative diagram:

We first claim that either  $N$  or  $Q''$  is zero. Suppose if possible both of them are non-zero. We note that as associate primes of  $\omega_A$  have dimension d it follows that dim  $N = d$ . Similarly dim  $Q'' = d$ . It follows that the modified multiplicity  $e(N), e(Q'')$  are positive. As dimensions of N, M, Q'' is d we get by [\[1,](#page-10-2) 4.7.7];  $e(N) + e(Q'') = e(M) = 1$ . This is a contradiction

Suppose if possible  $Q'' = 0$ . Then  $Q' = Q$ . We note that  $Q = M^{\vee} \neq 0$ . We note that  $Q$  is a d-dimensional quotient of  $A$  which is not  $A$  (as  $A$  is NOT regular). This is a contradiction as A is a domain. So  $N = 0$ . Thus  $V = \omega_A$ . We note that  $M = Q'$  is a MCM Q-module with multiplicity one. So  $Q'' \cong Q$ . Thus  $Q' = Q/(a)$  for some a. If  $Q' = 0$  then note that  $\omega_A \cong A$ . This forces A to be Gorenstein, a contradiction. So  $Q'$  is non-zero and note that codim  $Q' \leq 1$ . The result follows.

We have to prove a slightly more general version of the assertion (ii)  $\implies$  (i) of Theorem [1.1.](#page-1-1)

<span id="page-2-0"></span>**Theorem 2.1.** Let  $(A, \mathfrak{m})$  be a Cohen-Macaulay local ring of dimension  $d \geq 1$ . *Assume* A *is not Gorenstein. Assume* A *is a quotient of a regular local ring* T *. Suppose the canonical module*  $\omega_A$  *of* A *is isomorphic to a proper ideal* J *of* A *such that* codim  $A/J \leq 1$ *. Then A is a Teter ring.* 

<span id="page-2-1"></span>2.2. Before proving the above result we make the following remarks:

#### 4 TONY J. PUTHENPURAKAL

- (1) The ring  $A/J$  is a hypersurface ring (or regular local). We note that it suffices to show  $A/J$  is Cohen-Macaulay. To prove this note that depth  $A/J$ d−1. As  $e(J) = e(\omega) = e(A)$ , it follows from [\[1,](#page-10-2) 4.7.7] that dim  $A/J \leq d-1$ . The assertion follows.
- (2) Note that  $\omega_A \cong J$  has a rank as  $A/J$  is a torsion A-module. It follows that A is generically Gorenstein, see [\[1,](#page-10-2) 3.3.18].
- (3)  $A/J = Q/(a)$  for some regular local ring Q of dimension d. This follows from the fact that  $A/J$  is a local ring which has utmost hypersurface singularity is a quotient of a regular local ring  $T$ .

We now give

*Proof of Theorem [2.1.](#page-2-0)* By [2.2](#page-2-1) there exists a complete regular local ring Q of dimension d such that  $A/J = Q/(a)$  for some non-zero a. Let B be the fiber-product of  $A \to Q/(a) = A/J$  and  $Q \to Q/(a)$ . It is routine to verify that the induced homomorphisms  $p: B \to Q$  and  $q: B \to A$  are surjective. Also notice B is local. We have the following commutative diagram

$$
0 \longrightarrow \omega_A \xrightarrow{i} B \xrightarrow{p} Q \longrightarrow 0
$$
  
\n
$$
\downarrow f \qquad \qquad \downarrow q \qquad \qquad \downarrow \pi'
$$
  
\n
$$
0 \longrightarrow \omega_A \xrightarrow{i'} A \xrightarrow{\pi} Q/(a) \longrightarrow 0
$$

We note that f is an isomorphism, [\[6,](#page-10-3) Chapter III, 5.4]. As  $A, Q$  are quotient of T, so B is also a quotient of T. As we have an exact sequence  $0 \to \omega_A \to B \stackrel{p}{\to} Q \to 0$ is exact it follows that  $B$  is Cohen-Macaulay of dimension  $d$ . We may by using prime avoidance construct a sequence  $\mathbf{x} = x_1, \ldots, x_d$  which is an  $B \oplus \omega_A \oplus Q \oplus A$ regular sequence, such that images of  $x$  generate the maximal ideal of  $Q$ . Going mod x we obtain an exact sequence

$$
0 \to \omega_A / \mathbf{x} \omega A \to B / \mathbf{x} B \xrightarrow{\overline{p}} k \to 0.
$$

If  $t \in \text{soc}(B/\mathbf{x}B)$  then  $\overline{p(t)} = 0$ . It follows that  $\text{soc}(B/\mathbf{x}B) \cong \text{soc}(\omega_A/\mathbf{x}\omega_A) \cong k$  as  $\omega_A/\mathbf{x}\omega_A$  is the canonical module of  $A/\mathbf{x}A$ . Thus  $B/\mathbf{x}B$  is a Gorenstein ring and hence B is a Gorenstein ring. We note that  $\ker(B \stackrel{q}{\to} A) \cong \ker(Q \to Q/(a)) = Q$ . This we have an exact sequence  $0 \to M \to B \to A \to 0$  where  $M \cong Q$ . So  $e(M) = 1$ . Thus  $e(B) = e(A) + 1$ . It follows that A is a Teter ring.

We now give

*Proof of Theorem [1.1](#page-1-1) continued.* We already have proved (i)  $\implies$  (ii). The assertion (ii)  $\implies$  (i) follows from Theorem [2.1.](#page-2-0) We now have to prove uniqueness of the Teter Gorenstein approximation of A. Set  $C = A \times_{Q/(a)} Q$  the fiber-product and let  $j: C \to A$  and  $l: C \to Q$  be the natural maps. By the proof of (ii)  $\implies$ (i) we get that C is a Teter Gorenstein approximation of A. We prove  $B \cong C$ . By our proof of (i)  $\implies$  (ii) we obtain a commutative diagram

$$
0 \longrightarrow \omega_A \xrightarrow{i} B \xrightarrow{p} Q \longrightarrow 0
$$
  
\n
$$
\downarrow g \qquad \qquad \downarrow \pi'
$$
  
\n
$$
0 \longrightarrow \omega_A \xrightarrow{i'} A \xrightarrow{\pi} Q/(a) \longrightarrow 0
$$

where g is an isomorphism and  $p, q$  are surjective. By the universal property of fiber products we have a ring map  $\psi: B \to C$  such that  $p = l \circ \psi$  and  $q = j \circ \psi$ . So we have a commutative diagram

We note that  $g = f \circ u$  where  $f: \omega_A \to \omega_A$  is the isomorphism induced by the fiber-product diagram. As  $g$  is an isomorphism it follows that  $u$  is an isomorphism. So  $\psi$  is an isomorphism. The result follows.

## 3. Proof of Theorem [1.2](#page-1-0)

In this section we give

*Proof of Theorem [1.2.](#page-1-0)* Let  $(B, \mathfrak{n})$  be a Teter Gorenstein approximation of A. So we have an exact sequence  $0 \to M \to B \to A \to 1$  where M is a MCM B-module of multiplicity one. We note that we may assume that the residue field of  $B$  is infinite (otherwise we may consider  $B' = B[X]_{nB[X]}$  and  $A' = A \otimes_B B'$ ).

We induct on dimension d of A. When  $d = 0$  we have nothing to prove.

The case when  $d = 1$  is the most important case. Suppose if possible  $G(A)$  is *not* Cohen-Macaulay.

Consider the filtration  $\mathcal{F} = {\mathfrak{n}^n \cap M}_{n \geq 0}$  on M. We note that  $\mathcal{F}$  is an n-stable filtration on  $M$ . We have an exact sequence of  $G(B)$ -modules

$$
0 \to G_{\mathcal{F}}(M) \to G(B) \to G(A) \to 0.
$$

It follows that  $G_{\mathcal{F}}(M)$  is Cohen-Macaulay. Let x be  $B \oplus A$ -superficial and Msuperficial with respect to F. We note that  $e(M) = \ell(M/xM) = 1$ . So  $xM = \mathfrak{m}M$ and  $\mu(M) = 1$ . We shift F to get a new filtration  $\mathcal{G} = {\mathcal{G}_n}_{n>0}$  of M such that  $\mathcal{G}_0 = M$  and  $\mathcal{G}_1 \neq 1$ . We note that  $G_{\mathcal{G}}(M)$  is Cohen-Macaulay, say its h-polynomial is  $a_0 + a_1 z + \cdots + a_s z^s$ . Then as  $G_{\mathcal{G}}(M)$  is Cohen-Macaulay we get  $a_i \geq 0$ . Also  $a_0 \neq 0$  by construction. As  $e(G_{\mathcal{G}}(M)) = 1$  it follows that  $a_0 = 1$  and  $a_i = 0$ for  $i > 0$ . Thus  $e_1(G_{\mathcal{G}}(M)) = 0$ . It follows that  $G_{\mathcal{G}}(M) \cong k[Y]$ . It follows that  $G_{\mathcal{F}}(M) = k[Y](-a)$ . Let  $\alpha$  be the generator of M. Say image of  $\alpha$  in B is  $\xi$ . By going mod a  $B \oplus A$  and M-superficial element with respect to  $\mathcal F$  we obtain an exact sequence  $0 \to k \to \overline{B} \to \overline{A} \to 0$ . It follows that  $\overline{\alpha}$  maps to  $\delta$ , a generator of soc( $\overline{B}$ ). Say soc $(\overline{B}) = \mathfrak{n}^r$ . Thus  $\xi = \delta + \theta x$  where  $\theta \in B$ . So  $\operatorname{ord}_{\mathfrak{n}}(\xi) \leq r$ . So  $a \leq r$ .

If J is a non-zero homogeneous ideal of  $G(B)$  set

 $i(J) = \min\{\text{deg }t \mid t \in J \text{ where } t \text{ is non-zero and homogeneous }\}.$ 

We note that if  $J \subseteq J'$  then  $i(J') \leq i(J)$ . We note that  $i(G_{\mathcal{F}}(M)) = a$ .

Consider a primary decomposition of  $G_{\mathcal{F}}(M)$  as an ideal in  $G(B)$ . As  $G(A)$  is not Cohen-Macaulay we have

$$
G_{\mathcal{F}}(M) = Q_1 \cap Q_2 \cap \cdots \cap Q_s \cap L,
$$

where L is  $\mathfrak{M}$ -primary (here  $\mathfrak{M}$  is the unique homogeneous ideal of  $G(B)$ ) and  $Q_i$ is  $P_i$ -primary where  $P_i$  is some minimal prime of  $G(B)$ . Set  $Q = Q_1 \cap Q_2 \cap \cdots \cap Q_s$ .

Then Q is a Cohen-Macaulay ideal in  $G(B)$  and  $Q \supseteq G_{\mathcal{F}}(M)$ . We have an exact sequence

$$
0 \to G(B)/G_{\mathcal{F}}(M) \to G(B)/Q \oplus G(B)/L \to G(B)/(L+Q) \to 0.
$$

As L is a zero-dimensional ideal of  $G(B)$  we obtain  $e(G(B)/Q) = e(G(A))$  $e(B) - 1$ . It follows that  $e(Q)$  (as a  $G(B)$ -module) is one. We have an exact sequence of MCM  $G(B)$ -modules  $0 \to Q \to G(B) \to G(B)/Q \to 0$ . Going mod a regular element  $x^*$  of degree one we obtain a sequence  $0 \to Q/x^*Q \to G(\overline{B}) \to$  $G(B)/(Q+x^*G(B)) \to 0$ . As  $e(Q) = 1$  it follows that  $Q/x^*Q = k[-c]$  for some c. We note that the degree of socle of  $G(\overline{B})$  is also  $\text{ord}_{\overline{B}}(\text{soc}(\overline{B})) = r$ . So  $c = r$ . Thus  $Q = k[Y](-r)$ . Thus  $i(Q) = r$ . As  $Q \supseteq G_{\mathcal{F}}(M)$  we obtain  $r = i(Q) \leq i(G_{\mathcal{G}}(M))$  $a \leq r$ . So  $i(G_{\mathcal{F}}(M)) = r$ . Thus  $G_{\mathcal{F}}(M) = k[Y](-r)$ .

We now consider the exact sequence  $0 \to G_{\mathcal{F}}(M) \to G(B) \to G(A) \to 0$ . Going mod  $x^*$  where x is  $B \oplus A$  and M-superficial with respect to  $\mathcal F$  we obtain a sequence

$$
0 \to (0 \colon {}_{G(A)}x^*) \to k[-r] \xrightarrow{f} G(\overline{B}) \to G(A)/x^*G(A) \to 0.
$$

We note that  $f([\alpha]) = [\delta] \neq 0$ . Thus f is injective and hence  $(0: G_{(A)}x^*) = 0$ . So  $G(A)$  is Cohen-Macaulay.

Now assume dim  $A = d \geq 2$ . Let  $0 \to M \to B \to A \to 0$ . Let  $\mathbf{x} = x_1, \ldots, x_{d-1}$ be a  $A \oplus B \oplus M$ -superficial sequence. So we have an exact sequence  $0 \to \overline{M} \to \overline{B} \to$  $\overline{A} \to 0$ . We note  $e(\overline{M}) = 1$  and  $G(\overline{B})$  is Gorenstein. So by above argument  $G(\overline{A})$ is Cohen-Macaulay. By Sally descent, see [\[4,](#page-10-4) 2.2],  $G(A)$  is Cohen-Macaulay.  $\square$ 

## 4. Proof of Theorem [1.3](#page-1-2)

In this sections we give

*Proof of Theorem [1.3.](#page-1-2)* We may assume that the residue field of T is infinite. Otherwise consider the extension  $T \to T[X]_{nT[X]}$ . The hypotheses and conclusion of the theorem are invariant under this transformation.

Let  $d = \dim A \ge 1$ . As A is a Teter and a domain, by Theorem [1.1](#page-1-1) we have there exists a proper ideal J of A with  $J \cong \omega_A$  and codim  $A/J \leq 1$ . Furthermore  $A/J = Q/(a)$  where Q is a regular local ring of dimension d and  $a \neq 0$ . By Theorem [1.1](#page-1-1) we get  $B = A \times_{Q/(a)} Q$  is the unique (up to isomorphism) Teter Gorenstein approximation of A.

By [1.2](#page-1-0) we may assume that  $G(A)$  is Cohen-Macaulay. We note that by the exact sequence  $0 \to J \to A \to Q/(a) \to 0$  we obtain an exact sequence  $0 \to G_{\mathcal{F}}(J) \to$  $G(A) \to G(Q)/(a^*) \to 0$ . So  $G_{\mathcal{F}}(J)$  is Cohen-Macaulay.

Suppose  $d \geq 2$ . Then we choose  $\mathbf{x} = x_1, \ldots, x_{d-1}$  which is  $Q \oplus B \oplus A$  and  $\omega_A$  superficial with respect to F. Set  $(-) = (-) \otimes_T T/(\mathbf{x})$ . Then note  $G(B)$  is Gorenstein if and only if  $G(\overline{B})$  is Gorenstein. Furthermore  $G_{\mathcal{F}}(\omega)$  is isomorphic to the canonical module of  $G(A)$  (up to shift) if and only if  $G_{\overline{\mathcal{F}}}(\overline{\omega})$  is isomorphic to the canonical module of  $G(\overline{A})$  (up to shift). We also get  $\overline{B} \cong \overline{A} \times_{Q/(a,\mathbf{x})} \overline{Q}$ . However note  $\overline{A}$  need not be a domain. But this is not pertinent to our result (the only requirement is that  $\overline{B}$  is an appropriate fiber-product). Thus we may assume that  $d = 1$ . Consider the fiber-product exact diagram

We note  $q$  is an isomorphism.

Let **n** be the maximal ideal of B. As Q is a DVR we have  $nQ = (x)$ . We note j' is multiplication by  $x^r$  for some  $r \geq 1$ . On Q (on the left hand side) we have two filtration's. First set  $\mathcal{H} = \{j^{-1}(\mathfrak{n}^n)\}_{n\geq 0}$  and  $\mathcal{H}' = \{(j')^{-1}((x^n))\}_{n\geq 0}$ . Furthermore we have a natural injective map  $\mathcal{H}_n \to \mathcal{H}'_n$  for all  $n \geq 0$ . It is evident that  $\mathcal{H}' = \{(x)^{n-r}\}_{n\geq 0}$  (here  $(x)^l = Q$  if  $l \leq 0$ ). Note that  $\mathfrak{n} = \mathfrak{m} \times_{(x)/(x^r)} (x)$ . Let  $n \geq r$ . We note that  $(0, x^n) \in \mathfrak{n}^n$ . So by a diagram chase we obtain  $\mathcal{H}_n \supseteq (x^{n-r})$ As  $\mathcal{H}_n \subseteq \mathcal{H}'_n = (x^{n-r})$ . It follows that  $\mathcal{H}_n = (x^{n-r})$  for all  $n \ge r$ . For  $0 \le n \le r-1$ we note that  $\mathcal{H}_n \supseteq \mathcal{H}_r = Q$ . So  $\mathcal{H}_n = Q$  for  $n \leq r$ . It follows that  $\mathcal{H} \cong \mathcal{H}'$ .

We note that  $G_{\mathcal{H}}(Q) = k[X](-r)$ . We also have an exact sequence  $0 \rightarrow$  $G_{\mathcal{H}}(Q) \to G(B) \to G(A) \to 0$ . As  $G(A)$  is Cohen-Macaulay we obtain that  $G(B)$ is Cohen-Macaulay.

We note that we have an exact sequence  $0 \to \omega_A \to B \stackrel{p}{\to} Q \to 0$ . Set  $\mathcal{F}' =$  ${\{\omega_A \cap \mathfrak{n}^n\}}_{n\geq 0}$ . We also have an exact sequence  $0 \to J \to A \to Q/(a) \to 0$ , with  $J \cong \omega_A$  and the filtration  $\mathcal{F} = {\mathfrak{m}^n \cap J}_{n>0}$ . We had that  $G_{\mathcal{F}}(J)$  is Cohen-Macaulay. We have a commutative diagram

We had earlier shown that  $\mathcal{H}' \cong \mathcal{H}$ . So  $G(g)$  is an isomorphism. It follows by Snake Lemma that  $\psi$  is an isomorphism. Thus we have an exact sequence  $0 \rightarrow$  $G_{\mathcal{F}}(J) \to G(B) \to G(Q) \to 1$ . By going  $x^*$  which is  $G(B)$ -regular and of degree one we obtain an exact sequence

$$
0 \to G_{\mathcal{F}}(J)/x^*G_{\mathcal{F}}(J) \to G(\overline{B}) \to k \to 0.
$$

It follows that  $\operatorname{soc}(G_{\mathcal{F}}(J)/x^*G_{\mathcal{F}}(J)) = \operatorname{soc}(G(\overline{B}))$ . We note that  $G(B)$  is Gorenstein if and only if soc  $G(\overline{B}) = k$ . We also have  $G_{\mathcal{F}}(J)$  isomorphic to the canonical module of  $G(A)$  upto shift if and only if  $\operatorname{soc}(G_{\mathcal{F}}(J)/x^*G_{\mathcal{F}}(J)) = k$ . The result  $\Box$ follows  $\Box$ 

#### 5. Examples and proof of Theorem [1.4](#page-1-3)

In this section we give several examples which illustrate our results. We also give a proof of Theorem [1.4.](#page-1-3) Eisenbud and Herzog gave a complete list of homogeneous Cohen-Macaulay rings over an algebraically closed field k of characteristic zero which are of finite representation type. Our proof of Theorem [1.4](#page-1-3) is by a case by case analysis of the examples of Eisenbud and Herzog.

We first show

<span id="page-7-0"></span>**Proposition 5.1.** Let  $R = \bigoplus_{n \geq 0} R_n$  be a standard algebra over an infinite field  $k = R_0$ . We assume dim  $R = 1$  and that R is generically Gorenstein. Assume R *is Cohen-Macaulay with minimal multiplicity and that* R *is not Gorenstein. Let* M *be the maximal homogeneous ideal of R. Then*  $A = R_{\mathfrak{M}}$  *is a strong Teter ring.* 

*Proof.* We note that  $h_R(z) = 1 + hz$ . We also have that R is a level ring. So all generators of  $\omega$  have the same degree. We have a homogeneous inclusion  $J =$  $\omega_R(r) \to R$  with J a proper ideal. Choose  $x \in R_1$  which is R-regular. We note that  $R_n = xR_{n-1}$  for  $n \ge 2$ . If all generators of J are of degree  $\ge 2$  then  $J = xJ'$ for some ideal J' of R. We note that  $J' \cong J[+1] \cong \omega_R(r+1)$ . Thus we can assume that there exists an ideal K generated in degree one with  $K \cong \omega_R(s)$ . We have  $h_K(z) = h z + z^2$ . So  $h_{R/K}(z) = 1 + z$ . Also dim  $R/K = 0$ . It follows that  $R/K$  is a graded hypersurface ring. After completing we obtain that  $A$  is a Teter ring by Theorem [2.1.](#page-2-0)

We note that  $G(A) = A$  and  $G(\overline{R}/\overline{K}) = R/K$ . Thus the exact sequence  $0 \rightarrow$  $\omega_A \to A \to \overline{R}/\overline{K} \to 0$  induces an exact sequence  $0 \to G_{\mathcal{F}}(\omega_A) \to R \to R/K \to 0$ . So  $G_{\mathcal{F}}(\omega_A) \cong K$  is isomorphic to the canonical module of  $G(A) = R$  up to shift. It follows from [1.3](#page-1-2) that A is a strong Teter ring.  $\square$ 

<span id="page-7-2"></span>**Example 5.2.** Let  $R = k[X, Y, Z]/(XY, XZ, YZ)$ . Then R is of minimal multiplicity. Also it is not difficult to prove that  $R$  is reduced. So by Theorem [5.1](#page-7-0) we get that  $A = R(X,Y,Z) = k[[X, Y, Z]]/(XY, XZ, YZ)$  is a strongly Teter ring.

<span id="page-7-1"></span>**Example 5.3.** Let k be a field. Set  $S = k[X, Y]$  and let  $R = S^{\langle m \rangle}$  for some  $m \geq 3$ . Then  $A = \widehat{R}$  is strongly Teter.

**Remark 5.4.** We note that  $k[X, Y]^{<2>} = k[X^2, XY, Y^2]$  is a hypersurface ring and so Gorenstein.

We now give

*Proof of Example* [5.3.](#page-7-1) . We note that  $\omega_S = XYZ \subseteq S$ . By [\[3,](#page-10-5) 3.1.3] we get that  $\omega_R = \omega_S^{< m>}$ . We note that  $\omega_R \subseteq R$ . We note that  $\dim_k R_1 = m+1$ . Also note that  $(\omega_R)_1 = (\omega_S)_m = (X, Y)^{(m-2)}XY$ . So  $\dim_k(\omega_R)_1 = m-1$ . Thus the maximal ideal of  $R/\omega_R$  is generated by two elements and it is a Cohen-Macaulay ring of dimension one. So  $R/\omega_R$  is a hypersurface ring. After completing A is a Teter ring by Theorem [1.1.](#page-1-1) By an argument similar to proof of Proposition [5.1](#page-7-0) we get that  $A$ is strongly Teter.

**5.5.** Let H be an additive subsemigroup of  $\mathbb{N} = \{0, 1, 2, \dots\}$  with  $0 \in H$  such that  $\mathbb{N} \setminus H$  is finite. Let  $R = K[H]$  be the numerical semigroup ring of H. Set  $A = R = k[[H]]$ . We give a few examples of semigroup rings whose completions are Teter. The crucial observation is that

$$
\omega_R = \sum_{\alpha \in \mathbb{N} \backslash H} Rt^{-\alpha}, \quad \text{see [3, 2.1.9]}.
$$

<span id="page-8-2"></span>**Example 5.6.** Consider  $R = k[t^3, t^4, t^5]$ . Then  $A = \hat{R} = k[[t^3, t^4, t^5]]$  is a Teter ring.

*Proof:* We note that  $H = \{0, n, \text{where } n \geq 3\}$ . So  $\omega_R = Rt^{-1} + Rt^{-2}$ . Explicitly

$$
\omega_R = kt^{-2} + kt^{-1} + \sum_{n \ge 1} kt^n.
$$

We note that  $J = t^6 \omega_R \subseteq R$  and note that  $t^4, t^5 \in J$ . Thus the maximal ideal of  $R/J$  is generated by one element and dim  $R/J = 0$ . Hence it is a hypersurface ring. So A is a Teter ring by Theorem [1.1.](#page-1-1)

<span id="page-8-0"></span>**Example 5.7.** Consider  $R = k[t^4, t^5, t^{11}]$ . Then  $A = \hat{R} = k[[t^4, t^5, t^{11}]]$  is a Teter ring. However A is *not* strongly Teter.

*Proof:* We note that  $H = \{0, 4, 5, n, \text{where } n \geq 8\}$ . So

$$
\omega_R = Rt^{-1} + Rt^{-2} + Rt^{-3} + Rt^{-6} + Rt^{-7}.
$$

Explicitly

$$
\omega_R = kt^{-7} + kt^{-6} + kt^{-3} + kt^{-2} + kt^{-1} + \sum_{n \ge 1} kt^n.
$$

We note that  $J = t^{11} \omega_R \subseteq R$  and note that  $t^4, t^5 \in J$ . Thus the maximal ideal of  $R/J$  is generated by one element and dim  $R/J = 0$ . Hence it is a hypersurface ring. So  $A$  is a Teter ring by Theorem [1.1.](#page-1-1) By [\[7,](#page-10-6) p. 20],  $G(A)$  is NOT Cohen-Macaulay. So by [1.2](#page-1-0) we get that A is NOT strongly Teter.  $\Box$ 

**5.8.** *Integer matrix rings:* Let  $A = {}^{t}(a_1, \ldots, a_n)$  be an integer matrix and assume that the g.c.d of  $\{a_1, \ldots, a_n\}$  is 1. Define a grading of  $S = k[x_1, \ldots, x_n]$  by defining  $\deg x_i = a_i$ . We have  $S = \bigoplus_{n \in \mathbb{Z}} S_n$ . Set  $S_0 = R(A)$ . We have that each  $S_n$  is a  $R(A)$ -module. Let H is the sub-semigroup of  $\mathbb{N}^n$  consisting of  $\alpha = (\alpha_1, \dots, \alpha_n)$  with  $\sum_{i=1}^{n} a_i \alpha_i = 0$  then  $R(A)$  is the semigroup ring  $k[x^{\alpha} | \alpha \in H]$  where  $x^{\alpha}$  denotes  $x^{\alpha_1}x_2^{\alpha_2}\cdots x_n^{\alpha_n}$ . Note  $R(A)$  is naturally an N-graded ring. Set  $\widehat{R(A)} = k[[x^{\alpha}] \alpha \in$ H]. We note that  $R(A)$  and so  $R(A)$  are Cohen-Macaulay rings, see [\[10,](#page-10-7) 16.1].

<span id="page-8-1"></span>**Example 5.9.** Consider the integer matrix ring  $A = {}^{t}(2, -1, -1, -1)$ . Then  $\widehat{R(A)}$ is a Teter ring.

*Proof.* By [\[10,](#page-10-7) 16.10] we have

$$
R(A) = k[x_1x_2^2, x_1x_2x_3, x_1x_3^2, x_1x_3x_4, x_1x_4^2, x_1x_2x_4].
$$

We note that dim  $R(A) = 3$ . We also have  $S_1 = (x_1x_2, x_1x_3, x_1x_4)R(A)$  is isomorphic to the canonical module of  $R(A)$  (up-to shift). We have  $x_2S_1 \subseteq R(A)$  and note that

$$
x_2S_1 = (x_1x_2^2, x_1x_2x_3, x_1x_2x_4).
$$

So the graded maximal ideal of  $R(A)/x_2S_1$  is generated by 3 elements. As  $\dim R(A)/x_2S_1$  is two and it is Cohen-Macaulay it follows that  $R(A)/x_2S_1$  is a hypersurface ring. Taking completions it follows that  $\widehat{R(A)}$  is a Teter ring by Theorem [1.1.](#page-1-1)  $\Box$ 

<span id="page-9-0"></span>**Example 5.10.** Consider the integer matrix ring  $C = {}^{t}(2, 1, -1, -1)$ . Then  $\widehat{R(C)}$ is a Teter ring.

*Proof.* By [\[10,](#page-10-7) 16.12] we have

 $R(C) = k[x_1x_3^2, x_1x_3x_4, x_1x_4^2, x_2x_3, x_2x_4].$ 

We note that dim  $R(C) = 3$ . We also have  $S_{-1} = (x_3, x_4)R(C)$  is isomorphic to the canonical module of  $R(A)$  (up-to shift). We have  $x_1x_3S_{-1} \subseteq R(A)$  and note that

$$
x_1 x_3 S_{-1} = (x_1 x_3^2, x_1 x_3 x_4).
$$

So the graded maximal ideal of  $D = R(A)/x_1x_3S_{-1}$  is generated by 3 elements. As  $\dim D$  is two and it is Cohen-Macaulay it follows that D is a hypersurface ring. Taking completions it follows that  $R(C)$  is a Teter ring by Theorem [1.1.](#page-1-1)

<span id="page-9-1"></span>**5.11.** Let k be an algebraically closed field of characteristic zero. Let R be a standard graded Cohen-Macaulay k-algebra of dimension d. Assume R is *not* Gorenstein and is of finite representation type. Then by  $[2]$ ; R is one of the following rings:

 $d = 1$ . Then R is isomorphic to  $k[X, Y, Z]/(XY, XZ, YZ)$ .

 $d = 2$ . Then R is isomorphic to  $k[X, Y]^{< m>}$  for some  $m \geq 3$ .

 $d = 3$ . Then R is isomorphic to either  $U = k[X, Y, Z]^{< 2}$  or R is isomorphic to  $V = k[X_1, X_2, X_3, X_4, X_5]/(X_1^2 - X_2X_3, X_2X_5 - X_1X_4, X_1X_5 - X_3X_4).$ We now give

*Proof of Theorem [1.4.](#page-1-3)* We prove case by case. Set  $d = \dim R$ . When  $d = 1$  we note that R is isomorphic to  $k[X, Y, Z]/(XY, XZ, YZ)$ . So by [5.2](#page-7-2) we get  $\widehat{R_{\mathfrak{M}}}$  is a Teter ring. When  $d = 2$  we have R is isomorphic to  $k[X, Y]^{< m>}$  for some  $m \geq 3$ . So by [5.3](#page-7-1) we get that  $\widehat{R_{\mathfrak{M}}}$  is a Teter ring. When  $d = 3$  we note that  $R(\overline{(2,-1,-1,-1)})$ is isomorphic to the completion of U, see [\[10,](#page-10-7) 16.10]. So by [5.9](#page-8-1) we get that  $\widehat{U_{\mathfrak{M}}}$  is Teter. We also have  $R(\overline{t(2,1,-1,-1)})$  is isomorphic to the completion of V, see [\[10,](#page-10-7) 16.12]. So by [5.10](#page-9-0) we get that  $\widehat{V_{\mathfrak{M}}}$  is Teter. The result follows.

**Remark 5.12.** Let k be a field of characteristic zero. Consider  $A = k[[t^3, t^4, t^5]]$ . In [5.6](#page-8-2) we proved that A is Teter. Note A bi-rationally dominates  $k[[t^3, t^4]]$  (which is  $E_6$ ). So A has finite representation type. Thus there exists examples of completions of non-homogeneous rings of finite representation type which are Teter.

Remark 5.13. We note that all the examples in [5.11](#page-9-1) have minimal multiplicity. Consider  $A = k[[t^4, t^5, t^{11}]]$  which is a Teter ring, see [5.7.](#page-8-0) We note A does not have minimal multiplicity.

**Example 5.14.** If  $(A, \mathfrak{m})$  is a Teter ring then it is easily verified that both  $A[X_1,\ldots,X_n]_{\mathfrak{n}}$  (where  $\mathfrak{n} = (\mathfrak{m},X_1,\ldots,X_n)$ ) and  $A[[X_1,\ldots,X_n]]$  are Teter rings. Applying this result to our examples creates bountiful examples of Teter rings which are domains.

It is perhaps pertinent to give an example of a local domain which is not Teter. To enable this we prove:

<span id="page-9-2"></span>Proposition 5.15. *Let* (A, m) *be a Cohen-Macaulay local ring of dimension* d*. If* A *is Teter then*  $type(A) = \mu(\mathfrak{m}) - d$ .

**Remark 5.16.** In the above proposition type  $(A)$  denotes the Cohen-Macaulay type of A, i.e., the  $k = A/\mathfrak{m}$  dimension of  $\text{Ext}_{A}^{d}(k, A)$ .

#### TETER RINGS 11

We now give

*Proof of Proposition [5.15.](#page-9-2)* We may assume that the residue field of A is infinite. Let  $B$  be a Gorenstein Teter approximation of  $A$ . We have an exact sequence  $0 \to M \to B \to A \to 0$ ; where  $e(M) = 1$ . We go mod **x** an  $M \oplus B \oplus A$ -superficial sequence. So we have  $0 \to k \to \overline{B} \to \overline{A} \to 0$ . So  $\overline{A}$  is Teter. We note that  $type(A) = type(\overline{A})$  and  $\mu(\overline{\mathfrak{m}}) = \mu(\mathfrak{m}) - d$ . Thus we can assume A is an Artin Teter ring.

Dualizing the sequence  $0 \to k \to B \to A \to 0$  we obtain an exact sequence  $0 \to$  $\omega_A \to B \to k \to 0$ . So we obtain a surjective map  $\omega_A \to \mathfrak{m}$  with kernel k. Thus we have exact sequence  $0 \to k \to \omega_A \to \mathfrak{m} \to 0$ . We apply the functor  $\text{Hom}_A(k, -)$  and noting that  $\omega_A$  is the canonical module of A we obtain  $\text{Hom}_A(k, \mathfrak{m}) \cong \text{Ext}^1_A(k, k)$ . Thus type( $A$ ) =  $\mu$ (m).

Example 5.17. Consider the following example from [\[8,](#page-10-9) p. 395]. Let

 $A = k[[t^5, t^6, t^7, t^9]]$ . We have  $\mu(\mathfrak{m}) = 4$ . But type(A) = 2. So A is not Teter by [5.15.](#page-9-2)
