(Dated: January 28, 2025)

Hydrogen production via the Hydrogen Evolution Reaction (HER) is critical for sustainable energy solutions, yet the reliance on expensive platinum (Pt) catalysts limits scalability. Zirconium-doped (Zr-doped) MXenes, such as Ti<sub>3</sub>C<sub>2</sub> and Ti<sub>3</sub>CN, emerge as transformative alternatives, combining abundance, tunable electronic properties, and high catalytic potential. Using first-principles density functional theory (DFT), we show that Zr doping at 3% and 7% significantly enhances HER activity by reducing the work function to the optimal range of 3.5-4.5 eV and achieving near-zero Gibbs free energy ( $|\Delta G_{H^*}|$ ) values of 0.18-0.16 eV, conditions ideal for efficient hydrogen adsorption and desorption. Bader charge analysis reveals substantial charge redistribution, with enhanced electron accumulation at Zr and N sites, further driving catalytic performance. This synergy between optimized electronic structure and catalytic properties establishes Zr-doped MXenes as cost-effective, high-performance alternatives to noble metals for HER. By combining exceptional catalytic efficiency with scalability, our work positions Zr-doped MXenes as a breakthrough for green hydrogen production, offering a robust pathway toward renewable energy technologies and advancing the design of next-generation non-precious metal catalysts.

### I. INTRODUCTION

The increasing global demand for energy, driven by industrial growth and population expansion, necessitates the urgent development of sustainable and eco-friendly energy solutions [\[1,](#page-5-0) [2\]](#page-5-1). Hydrogen, as a clean and renewable energy carrier, has emerged as a promising solution to these challenges, aligning with global sustainability goals [\[3,](#page-5-2) [4\]](#page-5-3). Among the various hydrogen production methods, the Hydrogen Evolution Reaction (HER), which relies on water splitting, has gained attention due to its cost-effectiveness and environmental benefits [\[5,](#page-5-4) [6\]](#page-5-5). The HER process efficiently produces hydrogen gas with water as a renewable source and oxygen  $(O<sub>2</sub>)$  as the sole byproduct, making it an attractive route for green energy conversion [\[7\]](#page-5-6).

Electrocatalysts are pivotal to HER efficiency, accelerating the reaction kinetics and reducing energy barriers [\[5\]](#page-5-4). Precious metal-based catalysts such as platinum (Pt) and ruthenium (Ru) are widely regarded for their superior catalytic performance, achieving low overpotentials and high cathodic current densities [\[8,](#page-5-7) [9\]](#page-5-8). However, the scarcity and prohibitive costs of these materials pose significant obstacles to their large-scale deployment, emphasizing the need for cost-effective alternatives [\[10,](#page-5-9) [11\]](#page-5-10). As a result, extensive research efforts are directed towards non-precious metal (NPM)-based electrocatalysts, which offer the potential to balance performance and cost [\[12](#page-6-0)[–14\]](#page-6-1).

Despite the progress made in NPM-based catalysts, chal-

lenges remain in optimizing their electrical conductivity and long-term stability in aqueous environments, which are critical to maintaining high catalytic activity and durability [\[15](#page-6-2)[–17\]](#page-6-3). Various classes of NPMbased catalysts, such as transition metal dichalcogenides (TMDs) [\[18\]](#page-6-4), metal nitrides [\[19\]](#page-6-5), and carbon-based materials like MXenes [\[20\]](#page-6-6), have been explored for HER applications. Among these, MXenes—two-dimensional (2D) transition metal carbides, nitrides, and carbonitrides—stand out for their promising catalytic properties, including excellent electrical conductivity, large surface areas[\[21,](#page-6-7) [22\]](#page-6-8), and tunable electronic structures[\[23\]](#page-6-9).

MXenes, represented by the general formula  $M_{n+1}X_nT_x$ , where M is a transition metal and X is carbon or nitrogen, possess surface terminations such as  $-F$ ,  $-O$ , or  $-OH$ [\[24](#page-6-10)[–26\]](#page-6-11). These materials have demonstrated high potential for HER due to their multiple active sites, robust mechanical properties, and hydrophilicity, which help their interaction with water molecules [\[27,](#page-6-12) [28\]](#page-6-13). Moreover, the tunability of their Fermi levels enhances their catalytic activity in HER by improving electron transfer efficiency [\[29,](#page-6-14) [30\]](#page-6-15). Nevertheless, the catalytic performance of MXenes in HER is primarily governed by the Gibb's free energy of hydrogen adsorption (∆*GH*<sup>∗</sup> ), with an optimal value close to zero being desirable for efficient hydrogen adsorption and desorption during the reaction [\[16,](#page-6-16) [22,](#page-6-8) [31,](#page-6-17) [32\]](#page-6-18).

In addition to  $|\Delta G_{\text{H}^*}|$ , the work function( $\phi$ ), defined as "the work needed to move an electron from a surface to a point in vacuum sufficiently far away from this surface [\[33\]](#page-6-19) has also emerged as a good catalytic descriptor in recent time [\[34,](#page-6-20) [35\]](#page-6-21). The value of  $\phi$  too less( $\leq 3eV$ ) or too high ( $\geq 6eV$ )hinders either the Volmer or the Heyrovsky/Tafle kinematics. The "habitable zone" of the  $\phi$ is found out to be in the range of 3.5-4.5eV[\[34,](#page-6-20) [36\]](#page-6-22).

Titanium carbide-based MXenes  $Ti<sub>3</sub>C<sub>2</sub>$  have garnered significant attention as potential catalysts for the hydrogen evolution reaction (HER) due to their tunable electronic structure, high surface area, and excellent hydrophilicity [\[37,](#page-6-23) [38\]](#page-6-24). However, their catalytic performance is limited by several shortcomings, including suboptimal hydrogen adsorption energy |∆*G*H<sup>∗</sup> |, insufficient active site density, and sluggish electron transfer kinet-ics [\[39\]](#page-6-25). The metallic nature of  $Ti<sub>3</sub>C<sub>2</sub>$  often leads to hydrogen adsorption that is either too strong or too weak, which hinders the HER process. Additionally, the surface terminations typically present on  $Ti<sub>3</sub>C<sub>2</sub>$ , such as  $-OH - F$ , and  $-O$ , introduce localized electronic states that are unfavorable for catalytic activity, thereby increasing the overpotential and reducing turnover frequency [\[40,](#page-6-26) [41\]](#page-6-27).

Doping has emerged as a promising strategy to address these limitations by modulating the electronic properties and surface chemistry of  $Ti<sub>3</sub>C<sub>2</sub>$ . Transition metal doping (e.g., Fe, Co, or Ni) can adjust the *d*-band center of Ti<sub>3</sub>C<sub>2</sub>, optimizing |∆*G*<sub>H</sub><sup>∗</sup>| and enhancing its catalytic activity[\[42\]](#page-6-28). Non-metal doping, such as nitrogen or boron, can further enhance charge redistribution and stabilize defect states, thereby improving electron transfer<sup>[\[31\]](#page-6-17)</sup>. For instance, Ni-doped Ti<sub>3</sub>C<sub>2</sub> has demonstrated significantly reduced overpotential and enhanced HER efficiency due to improved hydrogen adsorption and charge transport properties[\[42,](#page-6-28) [43\]](#page-7-0).

In this context, our study explores Zr-doped Ti-based MXenes as potential HER catalysts, aiming to overcome the limitations of pristine  $Ti<sub>3</sub>C<sub>2</sub>$  and  $Ti<sub>3</sub>CN$  monolayers. By introducing Zr dopants at concentrations of 3% and 7%, we investigate the impact of doping on the electronic structure, catalytic activity, and  $|\Delta G_{\rm H} \rangle$  values of these MXenes. Additionally, we examine the effects of hydrogen coverage on unterminated MXene monolayers to further elucidate the catalytic mechanisms. Our results demonstrate that Zr-doping can significantly enhance the HER catalytic performance of Ti-based MXenes, offering a pathway towards the development of cost-effective and efficient electrocatalysts for sustainable hydrogen production.

### II. COMPUTATIONAL DETAILS

All calculations were performed within the framework of density functional theory (DFT)[\[44\]](#page-7-1) using the projectoraugmented wave (PAW) method [\[45\]](#page-7-2), as implemented in the Vienna *Ab-initio* Simulation Package (VASP) [\[46–](#page-7-3) [49\]](#page-7-4). The exchange-correlation effects were treated using the Perdew-Burke-Ernzerhof (PBE) functional under the generalized gradient approximation (GGA) [\[50\]](#page-7-5). To ensure the accurate representation of valence electron-ion interactions, the plane-wave pseudopotential approach was employed, with a plane-wave cutoff energy set to 520 eV.

The primary focus of this work was on monolayer Tibased MXenes, both in pristine and Zr-doped configurations. A vacuum layer of approximately 16 Å was introduced along the *z*-axis to eliminate spurious interactions between periodic images of the layers. For structural relaxations, a convergence criterion of  $1.0 \times 10^{-3}$ eV/Å was adopted, ensuring precise ionic positions.

A Γ-centered Monkhorst-Pack [\[51\]](#page-7-6) *k*-point mesh of 14×  $14 \times 2$  was used for the MXene unit cell, with an equivalent *k*-point density applied to  $3 \times 3 \times 1$  supercells. The choice of this *k*-point sampling ensured adequate Brillouin zone integration for both pristine and doped systems. To capture the strong Coulombic interactions in the *d*-orbitals, the Hubbard *U* correction was applied using  $U_{\text{eff}} = 3.0 \text{ eV}$  for Ti [\[52\]](#page-7-7) and  $U_{\text{eff}} = 2.85 \text{ eV}$  for Zr [\[53\]](#page-7-8). The total energy minimization and convergence of force components were carefully monitored to ensure high accuracy in all simulations.

The thermodynamic stability of the MXene structures was evaluated by calculating the formation energy (*FE*) using the standard expression:

$$
FE(M_3C_2) = E(M_3C_2) - 3\mu_M - 2\mu_C, \qquad (1)
$$

where  $E(M_3C_2)$  represents the total energy of the MXene compound, and  $\mu_M$  and  $\mu_C$  are the chemical potentials of the metal and carbon atoms respectively, in their standard reference states.

The Volmer-Heyrovsky or the Volmer-Tafle reaction path of the HER  $(2H^+2e^- \rightarrow H_2)$ 

$$
H^{+} + e^{-} \rightarrow H^{*}
$$
 Volmer Step  
\n
$$
H^{*} + H^{+} + e^{-} \rightarrow H_{2} + *
$$
 Heyrovsky Step (2)  
\n
$$
2H^{*} \rightarrow H_{2} + 2*
$$
 Tafel Step

is largely controlled by the free energy of H absorption, or the Gibbs free energy (∆*GH*<sup>∗</sup> )[\[22,](#page-6-8) [31\]](#page-6-17). The necessary but insufficient condition for a material as "good" HER catalyst is  $|\Delta G_{H^*}| \approx 0$ . The free energy change for the intermediate H<sup>∗</sup> adsorption state is given by:

$$
\Delta G_{\text{H}^*} = \Delta E_{\text{H}^*} + \Delta ZPE_{\text{H}^*} - T\Delta S_{\text{H}^*}
$$
  

$$
\Delta E_{\text{H}^*} = E_{\text{Layer} + \text{H}^*} - E_{\text{Layer}} - \frac{1}{2}E_{\text{H}_2},
$$
(3)

where Δ*E*<sub>H<sup>∗</sup></sub> is the adsorption energy of hydrogen,  $E_{\text{Layer}+H^*}$  and  $E_{\text{Layer}}$  represent the total energies of the hydrogen-adsorbed and clean MXene surfaces, respectively, and  $E_{\rm H_2}$  is the total energy of molecular hydrogen in the gas phase.

<span id="page-2-0"></span>

FIG. 1: Monolayer structures of [\(a\)](#page-2-0)  $Ti<sub>3</sub>C<sub>2</sub>$ ; [\(b\)](#page-2-0)  $(Ti_{.97}Zr_{.03})_{3}C_{2}$ ; [\(c\)](#page-2-0)  $(Ti_{.93}Zr_{.07})_{3}C_{2}$ ; [\(d\)](#page-2-0)  $Ti_{3}CN$ ; [\(e\)](#page-2-0)  $(Ti_{.97}Zr_{.03})_{3}CN$ ; and [\(f\)](#page-2-0)  $(Ti_{.93}Zr_{.07})_{3}CN$ . Ti, Zr, C and N atoms are depicted as maroon, green, orange and violet balls, respectively.

The zero-point energy correction (Δ*ZPE*<sub>H<sup>∗</sup></sub>) accounts for the quantum vibrational effects of the adsorbed hydrogen atom, with values ranging from 0.01 to 0.04 eV for metal surfaces[\[54\]](#page-7-9). (*T*∆*S*<sub>H</sub><sup>\*</sup>), approximately 0.4 eV at room temperature, reflects the entropy difference between the adsorbed hydrogen and the gas-phase  $H_2$ molecule [\[55,](#page-7-10) [56\]](#page-7-11). Based on Nørskov's volcano plot, optimal HER catalysts exhibit |∆*G*H<sup>∗</sup> | ≤ 0.3 eV [\[55\]](#page-7-10), a criterion we employed to identify promising electrocatalysts.

The work function has been calculated using

$$
\phi = e\phi_{vaccum} - E_F
$$

where  $\phi_{vacuum}$  is the potential far away from the surface.

## III. RESULTS AND DISCUSSION

FIG. [\(1\)](#page-2-0) shows the schematic of the dopped and undopped structures used in this study. FIG. [\(1a\)](#page-2-0) and FIG. [\(1d\)](#page-2-0) shows the  $T_3C_2$  and  $T_3CN$  structures respectively. FIG. [\(1b\)](#page-2-0) and FIG. [\(1c\)](#page-2-0) are showing 0.3% and 0.7% doping of  $Zr$  at Ti site of  $T_3C_2$ (Those structures will be referred as  $TZ_3C$  and  $TCZ_7$  for brevity in the rest of this manuscript). FIG.  $(1e)$  and FIG.  $(1f)$  are showing 0.3% and 0.7% doping of Zr at Ti site of  $T_3CN$ , and will be referred as  $TZ_3CN$  and  $TZ_7CN$  in the rest of the manuscript. All the dopped systems are found to be thermodynamically stable (2nd column of table [\(I\)](#page-3-0)). Note that increased Zr doping in  $T_3C_2$  makes the system unstable, but due to higher electronegativity of N compared to C,  $Zr$  doped  $Ti<sub>3</sub>CN$  shows the increase in stability. The result aligns with the reported energy above the hull values of 0.05 eV/atom for  $Ti<sub>3</sub>C<sub>2</sub>[57]$  $Ti<sub>3</sub>C<sub>2</sub>[57]$  and 0.02 eV/atom for  $Zr_3N_2[58]$  $Zr_3N_2[58]$ , indicating enhanced stability of the Zr-dopped system.

The catalytic performance of each of the above systems are evaluated through calculations of the |∆*G*H<sup>∗</sup> | as dis-cussed above. FIG. [\(2a\)](#page-3-1) shows the  $|\Delta G_{\rm H} \rangle$  of the systems studied. The results shows systematic decrease of |∆*G*H<sup>∗</sup> | with higher concentrations of Zr. For pristine Ti<sub>3</sub>C<sub>2</sub>, the  $\Delta G_{\text{H}^*}$  value is 1.510 eV, while Ti<sub>3</sub>CN shows a slightly lower value of 1.251 eV, both of which indicate suboptimal HER activity. In contrast, the introduction of Zr into the MXene lattice significantly reduces  $|\Delta G_{\text{H}^*}|$ , with  $TZ_7C$  and  $TZ_7CN$  exhibiting values of 0.185 eV and 0.160 eV, respectively. These values are remarkably close to the ideal range for HER, suggesting that Zr-doping dramatically enhances the catalytic efficiency of the MXenes. The values are tabulated in table [\(I\)](#page-3-0) for comparison.

To elucidate the origin of the significant reduction in  $|\Delta G_{\rm H} \rangle$  observed with Zr doping, we performed comprehensive electronic structure calculations to determine the work function  $(\phi)$  and Bader charge distribution. The work function is a critical parameter in determining the efficiency of materials for the HER. FIG. [\(2b\)](#page-3-1) shows the  $\phi$  with respect to the surface. We observe significant variations in  $\phi$  with doping concentration. The pristine MXenes,  $Ti<sub>3</sub>C<sub>2</sub>$  and  $Ti<sub>3</sub>CN$ , exhibit relatively higher work functions, limiting their HER performance. Upon doping with 3% Zr, i.e.  $TZ_3C$  and  $TZ_3CN$ , show reduced work functions, nearing the optimal range, suggesting enhanced catalytic activity. Increasing the Zr content to 7% in TZC<sub>7</sub> and TZ<sub>7</sub>CN further takes the work function squarely within the desired range. This systematic change demonstrates that Zr doping effectively tunes the electronic properties of MXenes, enhancing their HER efficiency. Furthermore, the correlation between |∆*G*<sub>H</sub><sup>∗</sup>| and the work function, illustrated in FIG. [\(2c\)](#page-3-1), reveals a robust linear relationship, underscoring the direct impact of electronic structure modifications on catalytic performance. These findings align with prior studies that have demonstrated a strong link between the electronic properties of MXenes and their catalytic

<span id="page-3-1"></span>

FIG. 2: [\(a\)](#page-3-1)|∆*G*H<sup>∗</sup> | for the MXene systems studied, with reference to Pt;[\(b\)](#page-3-1) calculated work function normal to the surface. The dotted part of each curves are the constant line for comparison, and not actually calculated. Inset shows the zoomed in figure for better visualization. The line color indicates same systems as in [\(a\)](#page-3-1); and [\(c\)](#page-3-1) correlation between  $\phi$  and  $|\Delta G_{\text{H}^*}|$ .

activity[\[41\]](#page-6-27). The observed trend suggests that Zr doping not only tunes the electronic environment but also optimizes the catalytic properties of the material, making Zr-doped Ti-based MXenes a promising candidates for HER applications.

We systematically investigated the electronic structure of pristine and  $Zr$ -doped  $T_{13}C_2$  to elucidate the correlation between their electronic properties and catalytic performance in the hydrogen evolution reaction (HER). Pristine  $Ti_3C_2$ , a well-studied MXene, exhibits high electrical conductivity due to its metallic nature, characterized by a substantial density of states (DOS) near the Fermi level, as shown in FIG. [\(3a\)](#page-4-0). The layered structure of  $Ti_3C_2$  helps efficient electron mobility, a critical factor for enhancing catalytic reactions. Likewise, Ti3CN, which has mixed carbon and nitrogen occupancy at the X-sites, demonstrates comparable electronic behavior (FIG.  $(3d)$ ). These results are consistent with earlier DFT studies that have highlighted the metallic character of pristine MXenes and their capacity for electron transfer in various catalytic contexts [\[59,](#page-7-14) [60\]](#page-7-15). Introducing Zr atoms into the MXene structure at 3% and 7% concentrations induces notable changes in the electronic structure. The DOS of the Zr-doped MXenes (Figure [3\(b,c,e,f\)](#page-4-0)) shows an increase in electronic states near the Fermi level, particularly between -0.5 eV and -3.0 eV. This increase is attributed to Zr's larger electron affinity compared to Ti, resulting in enhanced electron donation. The higher DOS at the Fermi level for the Zrdoped structures indicates a greater availability of electrons, which is critical for promoting catalytic reactions. These additional states effectively lower the energy barrier for electron transfer to adsorbed hydrogen ions (H<sup>+</sup>), thereby facilitating HER [\[61\]](#page-7-16).

<span id="page-3-0"></span>

TABLE I: Formation energies  $(E<sub>form</sub>)$ , Gibbs free energies |∆*G*<sub>H</sub><sup>∗</sup>| for hydrogen adsorption on sufaces, and the bond lengths of pristine and Zr-doped MXenes. The value in the brackets are the experimental values obtained by other groups. The values differ primarily due to the choice of terminators and the choice PBE potentials.

FIG. [\(4\)](#page-4-1) illustrates the Bader charge analysis for four MXene systems. The pristine  $Ti<sub>3</sub>C<sub>2</sub>(FIG. (4a))$  $Ti<sub>3</sub>C<sub>2</sub>(FIG. (4a))$  $Ti<sub>3</sub>C<sub>2</sub>(FIG. (4a))$  shows low charge accumulation of Ti and C atoms. In contrast, Zr doping, where  $|\Delta G_{\rm H} \rangle$  is reduced to  $\approx -0.1$  eV, accumulates large charge on the Zr and N atoms, as shown in  $TZ_3C(FIG. (4b))$  $TZ_3C(FIG. (4b))$  $TZ_3C(FIG. (4b))$  and  $TZ_7CN (FIG. (4d)).$  $TZ_7CN (FIG. (4d)).$  $TZ_7CN (FIG. (4d)).$   $Ti_3CN,TZ_3C$ and  $TZ<sub>3</sub>CN$  shows the similar trend of higher charge accumulation in Zr and N compared to Ti and C and results in lower  $|\Delta G_{\rm H<sup>*</sup>}|$ .

The enhanced catalytic performance of Zr-doped MXenes can be attributed to the synergistic role of Zr and N. Zr, with its higher electron affinity compared to Ti, facilitates greater charge redistribution within the lattice, increasing surface electron availability crucial for HER. N, being more electronegative than C, stabilizes hydro-

<span id="page-4-0"></span>

FIG. 3: Calculated total DOS of monolayer [\(a\)](#page-4-0)  $Ti_3C_2$ , [\(b\)](#page-4-0)  $(Ti_{.97}Zr_{.03})_3C_2$ , [\(c\)](#page-4-0)  $(Ti_{.93}Zr_{.07})_3C_2$ , [\(d\)](#page-4-0)  $Ti_3CN$ , [\(e\)](#page-4-0)  $(Ti_{.97}Zr_{.03})_3CN$ , and [\(f\)](#page-4-0)  $(Ti_{.93}Zr_{.07})_3CN$  using Hubbard parameter  $U(U = 3.0$  for Ti and  $U = 2.85$  for Zr).

<span id="page-4-1"></span>

FIG. 4: Charge density distribution in [\(a\)](#page-4-1) Ti<sub>3</sub>C<sub>2</sub>; [\(b\)](#page-4-1) TZ<sub>3</sub>C<sub>3</sub> [\(c\)](#page-4-1) Ti<sub>3</sub>CN [\(d\)](#page-4-1) TZ<sub>7</sub>CN. Ti<sub>3</sub> Zr, C and N atoms are depicted as maroon, green, orange and violet balls, respectively.

gen adsorption by modifying the local electronic environment. This combination fine-tunes the Gibbs free energy and provides more favorable adsorption sites for H\* intermediates.

In summary, our results reveal that Zr-doping of  $Ti<sub>3</sub>C<sub>2</sub>$ and Ti<sub>3</sub>CN MXenes significantly enhances their catalytic performance for HER by modifying the electronic structure and reducing the Gibbs free energy of hydrogen adsorption. The improved electron mobility and increased surface electron density, along with the lowered work function, contribute to the superior catalytic efficiency of the Zr-doped MXenes. These findings highlight the potential of Zr-doped MXenes as promising candidates for sustainable hydrogen production, rivalling the performance of traditional platinum-based catalysts.

## IV. CONCLUSION

Our study demonstrates the significant catalytic potential of Zr-doped Ti-based MXenes for the hydrogen evolution reaction (HER). Specifically, the Zr-doped singlelayered MXenes  $(Ti_{.97}Zr_{.03})_3C_2$  and  $(Ti_{.97}Zr_{.03})_3CN$  exhibit Δ*G*<sub>H</sub><sup>∗</sup> values around 0.3 eV, while higher Zr concentrations, as seen in  $(Ti_{.93}Zr_{.07})_3C_2$  and  $(Ti_{.93}Zr_{.07})_3CN$ , result in optimal values of 0.18 and 0.16 eV, respectively. These near-zero Δ*G*<sub>H</sub><sup>∗</sup> values indicate that Zr-doped MXenes, particularly at higher doping levels, have excellent hydrogen adsorption properties, approaching the catalytic efficiency of platinum-based catalysts.

Our density of states (DOS) analysis confirms that Zr doping enhances the metallic character and increases the electron density near the Fermi level, which is pivotal for efficient electron transfer during HER. The improved electronic properties directly translate into enhanced catalytic activity, as demonstrated by the reduction in ∆*G*<sub>H<sup>∗</sub></sup> and lower work functions observed in the</sub> doped structures. This enhanced electron mobility and surface electron density, driven by Zr's introduction, significantly reduces the energy barrier for hydrogen adsorption, thereby facilitating HER.

An important distinction in our study is the focus on unterminated MXenes, a departure from the majority of existing literature, which primarily investigates MXenes with surface terminations such as  $-<sub>O</sub>$ ,  $-<sub>O</sub>H$ , or  $-F$ . While surface terminations are often considered to stabilize MXenes and enhance their chemical reactivity, they introduce complexity that can obscure the intrinsic properties of the material. By studying unterminated MXenes, we isolate the electronic and catalytic behaviors of the pristine 2D structures, providing a clearer understanding of their core material properties. This approach allows for an evaluation of the impact of Zr doping on the electronic structure and catalytic activity, particularly in the context of hydrogen evolution reactions (HER). Furthermore, insights gained from unterminated MXenes form a crucial baseline for future studies, facilitating a deeper comprehension of how surface functionalization affects performance. Thus, our study offers a more fundamental exploration of MXene chemistry, which is essential for designing next-generation HER catalysts.

These findings underscore the potential of Zr-doped Tibased MXenes as highly efficient and cost-effective alternatives to noble metal catalysts for hydrogen production. The ability to tailor the electronic structure through controlled doping opens new pathways for optimizing 2D MXenes for energy conversion technologies. This study paves the way for experimental validation and further exploration of Zr-doped MXenes in sustainable hydrogen production via water splitting, offering a promising avenue for green energy applications. Future work could focus on the experimental validation of Zr-doped Ti-based MXenes to confirm the theoretical predictions. Exploring other dopants, their synergetic effects, and the influence of surface terminations under different environmental conditions would provide deeper insights into optimizing HER activity. Additionally, integrating machine learning techniques to identify optimal compositions could accelerate the discovery of efficient catalysts for sustainable hydrogen production.

## ACKNOWLEDGMENTS

We express our sincere gratitude to the high performance computing center (HPCC), SRMIST and the Department of Physics and Nanotechnology for their support of the computational facility. We are appreciative of the computational resource provided by the National Param supercomputing facility (NPSF, CDAC), Government of India. We also express our heartiest gratitude to Selective Excellence Research Initiative (SERI), SRMIST for their support in our research work.
