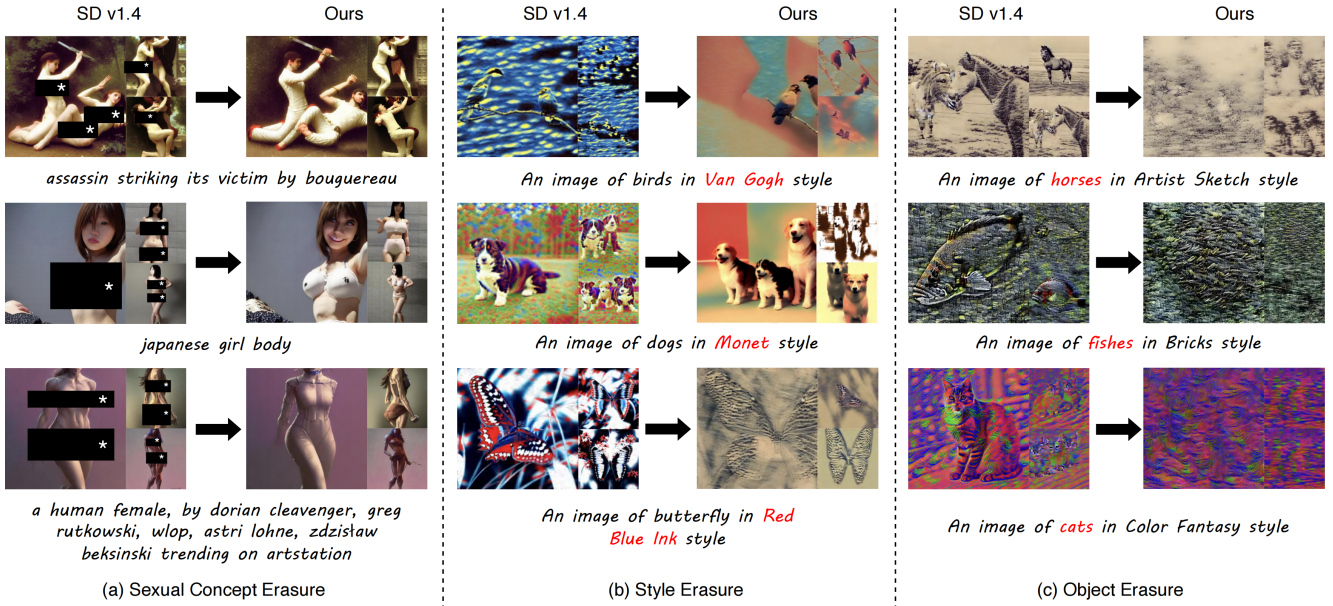

Figure 1. Demonstration of our concept erasure method, which effectively removes undesired visual concepts from generated images. (a) Our method effectively removes explicit content related to sexual themes, even when the text condition is seemingly unrelated to such concepts, achieving a clothed appearance while preserving visual coherence. (b) Our approach prevents the generation of content in specific artistic styles (e.g., Van Gogh, Monet), thereby respecting artistic copyrights and avoiding unintended imitation. (c) Our method demonstrates its capacity to erase entire object classes while preserving the model’s performance on unrelated artistic styles.

Abstract

Large-scale text-to-image (T2I) diffusion models have achieved remarkable generative performance about various concepts. With the limitation of privacy and safety in practice, the generative capability concerning NSFW (Not Safe For Work) concepts is undesirable, e.g., producing sexually explicit photos, and licensed images. The concept era-

sure task for T2I diffusion models has attracted considerable attention and requires an effective and efficient method. To achieve this goal, we propose a CE-SDWV framework, which removes the target concepts (e.g., NSFW concepts) of T2I diffusion models in the text semantic space by only adjusting the text condition tokens and does not need to re-train the original T2I diffusion model’s weights. Specifically, our framework first builds a target concept-related

word vocabulary to enhance the representation of the target concepts within the text semantic space, and then utilizes an adaptive semantic component suppression strategy to ablate the target concept-related semantic information in the text condition tokens. To further adapt the above text condition tokens to the original image semantic space, we propose an end-to-end gradient-orthogonal token optimization strategy. Extensive experiments on I2P and UnlearnCanvas benchmarks demonstrate the effectiveness and efficiency of our method.

1. Introduction

In recent year, large-scale text-to-image (T2I) models [39, 45, 47, 53, 69] have remarkable generative capabilities to synthesize realistic images. Unfortunately, the internet-sourced datasets used in training are often not rigorously filtered and frequently contain NSFW (Not Save For Work) concepts [26], and copyrighted materials [50]. Due to the limitation of privacy and safety in practice, these samples can cause models to learn and produce harmful content that could breach social norms.

To make generative models reasonably applicable, researchers have introduced the concept erasure task for T2I models, which prevents generated images from containing undesired concepts (i.e., target concepts [29, 34]). Typically, An optimal concept erasure method should balance the effectiveness [29, 34] and efficiency [31, 66]. Regarding effectiveness, the generated visual content must ensure target concepts suppression and irrelevant concepts preservation. In terms of efficiency, erasure methods should minimize both storage overhead and computational time. However, most model-based tuning methods [9, 11, 14–16, 18, 22, 24, 29, 35, 37, 57, 59, 63, 65] involve modifying model parameters and usually require additional parameter storage and training overhead. The recent text-based suppression method aims at suppressing information of target concepts in text embeddings, but predefining suppressed words hinders its effectiveness in special sentences (e.g., cases in Figure 1(a)). Our work focuses on the text-based suppression method, as it adjusts text conditions without modifying T2I models, thereby achieving high efficiency.

To suppress target concepts, the primary concerns are the accurate representation and precise removal of these concepts. Existing methods [29, 34, 59, 63] typically assume a link between target concepts and specific words (i.e., target words). These target words are encoded into target tokens and input into the generative models. For instance, to erase the sexual concept, researchers have constructed text conditions containing words like “naked” as study cases. However, such word-based concept representation presents two issues: 1) fails to accurately represent target concepts in biased [48] or memorized [29, 31] words; 2) fails to effec-

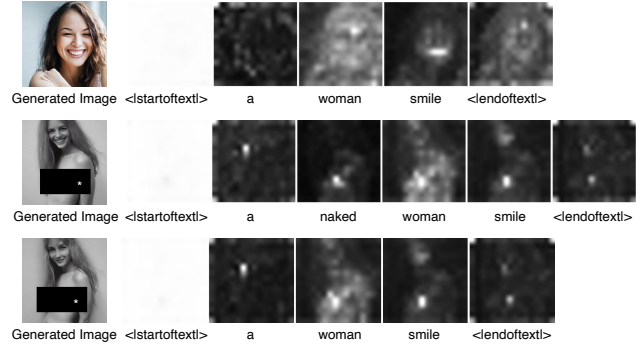

Figure 2. Information related to the target concept, concealed within other text tokens, can be utilized by diffusion models to reproduce the corresponding content. In the comparison between the first and second rows, the attention maps indicate that introducing the word “naked” causes noticeable changes to the information of EOT (end of text) and “smile” token, both of which now contain information derived from “naked”. In the third row, even after removing the word “naked”, the hidden information still allows SD v1.4 to generate content related to the sexual concept.

tively represent the target concept information of irrelevant tokens concealed by attention mechanism from the target tokens [31, 34, 56], as shown in Figure 2. The hidden information in irrelevant text tokens can be exploited by Stable Diffusion [45] (SD) v1.4 to regenerate erased concept content. Motivated by the above observations, the effective suppression of target concepts in text conditions meets the challenge of accurate target concepts representation and precise specific information erasure from each text token.

After the effective suppression of target concepts in text conditions, the original T2I diffusion model can generate images containing only irrelevant concepts. However, we observe that suppressed text tokens do not adapt well to the original image semantic space, resulting in low-quality detail generation for these irrelevant concepts [31]. The original image semantic space is relative to the unsuppressed text tokens, which can achieve high-quality detail generation on both the target and irrelevant concepts [68]. Therefore, the effective detail generation of irrelevant concepts in text conditions faces the challenge of adapting the suppressed text tokens to the original image semantic space.

In light of these challenges, we propose a CE-SDWV framework, an effective and efficient **C**oncept **E**rasure for T2I diffusion models via a **S**emantic-Driven **W**ord **V**ocabulary. Our framework defines three stages: semantic-driven concept representation, adaptive component suppression, and gradient-orthogonal token optimization. In the first stage, we employ large language models [1, 62] (LLM) to construct a word vocabulary and corresponding sentences related to target concepts. We then build a semantic text token matrix that contains target concept information. Given that the attention mechanism cause the text tokens to carry information from irrelevant concept tokens, we extract the

top-k principal components from the text token matrix and create a semantic space describing target concepts. In the adaptive component suppression, each token in the text conditions adaptively ablates the target concept components with respect to the semantic space. This approach effectively resolves the issue of target concept information being concealed within the tokens. To further adapt the suppressed text tokens to the original image semantic space, we introduce an end-to-end gradient-orthogonal optimization strategy [46] to optimize the suppressed text tokens from the original image space. This orthogonal approach prevents the re-generation of suppressed target concepts during the optimization process and enhances the detail generation for preserved irrelevant concepts. We evaluate our method for erasing sexual concepts, styles, and objects across the I2P [48] and UnlearnCanvas [66] benchmarks, achieving superior results in comprehensive performance.

2. Related Work

2.1. Text-to-Image Synthesis

Text-to-image synthesis has evolved significantly over the years. Beginning with Generative Adversarial Networks (GANs)[13, 25, 43], these models can effectively generate faces and categorical objects but struggle to create complex scenes that align with textual conditions. Subsequent research explores the use of transformers[6, 13, 54] and diffusion models [3, 4, 10, 21, 36, 55], with their corresponding large-scale models demonstrating outstanding capabilities in generating high-fidelity images from textual descriptions. DALL-E [41] is trained on a large dataset of text-image pairs, utilizing autoregressive transformers to generate high-quality images from textual descriptions. SD v1 [45] employs conditional diffusion models to achieve superior generation capabilities on the LAION-2B [49] dataset. Moreover, SD v2 [45] is trained on a subset of LAION-2B, with data filtered by an NSFW detector. However, studies [34, 48] point out that SD v2 still learns NSFW concepts from the dataset and generate inappropriate and harmful content. In this context, our method aims to mitigate such issues by effectively removing undesired concepts from generative models, ensuring safer and more controlled image generation.

2.2. Concept Erasure in T2I Diffusion Models

Existing research in T2I diffusion models can be broadly divided into four categories: training from scratch with curated datasets [36, 44], model-based tuning [9, 11, 14–16, 18, 22, 24, 29, 34, 35, 37, 57, 59, 63, 65], inference guidance [2, 48], and text-based suppression [31]. Retraining with curated datasets is impractical due to the substantial financial resources and significant time investment required. Model-based tuning involves modifying model pa-

rameters and usually requires additional parameter storage and training overhead. The inference guidance method adjusts conditional estimated noise during the sampling process but often fails in specific cases [34] within the I2P dataset [48]. In text-based methods, SEOT [31] constructs a matrix that includes both the text tokens to be erased and the EOT tokens, applying a soft-weighted regularization on the primary singular values to suppress the target concept information. However, this approach relies on prior knowledge of the specific words that need to be suppressed, making it ineffective when dealing with sentences that do not explicitly contain words related to target concepts. Our method can adaptively erase target concepts in text conditions without predefining words to be erased, facilitating the flexibility in diverse sentences.

2.3. Adversarial Prompt Attack

The adversarial prompt attack is a technique used to manipulate text prompts to deceive the model into generating content that bypasses its built-in constraints or safety filters. Adversarial attacks have been extensively studied in language models, with typical modifications including additions, deletions, and substitutions at the word level [23, 33, 61]. Recent research extends adversarial attack techniques to T2I diffusion models. CCE [38] leverages textual inversion [12] to learn specialized input word embeddings that bypass concept erasure methods. P4D [7] constructs adversarial prompts by optimizing prompt embeddings within a dual-model framework, aligning the outputs of an erased diffusion model with those of an unconstrained model to generate similar inappropriate content. Unlearn-DiffAtk [67] utilizes the inherent classification abilities of diffusion models to generate adversarial prompts without requiring auxiliary models. Building on these approaches, subsequent studies [16, 27, 65] propose new frameworks that employ adversarial prompts to improve the erasure of target concepts by further training models. Our work effectively defends against adversarial prompt attacks without requiring multi-round training, achieving a good trade-off between effectiveness and efficiency.

3. Method

We propose CE-SDWV, a novel framework for concept erasure in T2I diffusion models that prioritizes both effectiveness and efficiency. Our approach aims to accurately suppress target concepts while preserving irrelevant ones, achieving high-quality generation with minimal overhead. Figure 3 presents an overview of our framework.

3.1. Semantic-Driven Concept Representation

The premise of the concept erasure task is the accurate representation of target concepts. Inaccurate concept representation can lead to unintended results during the erasure

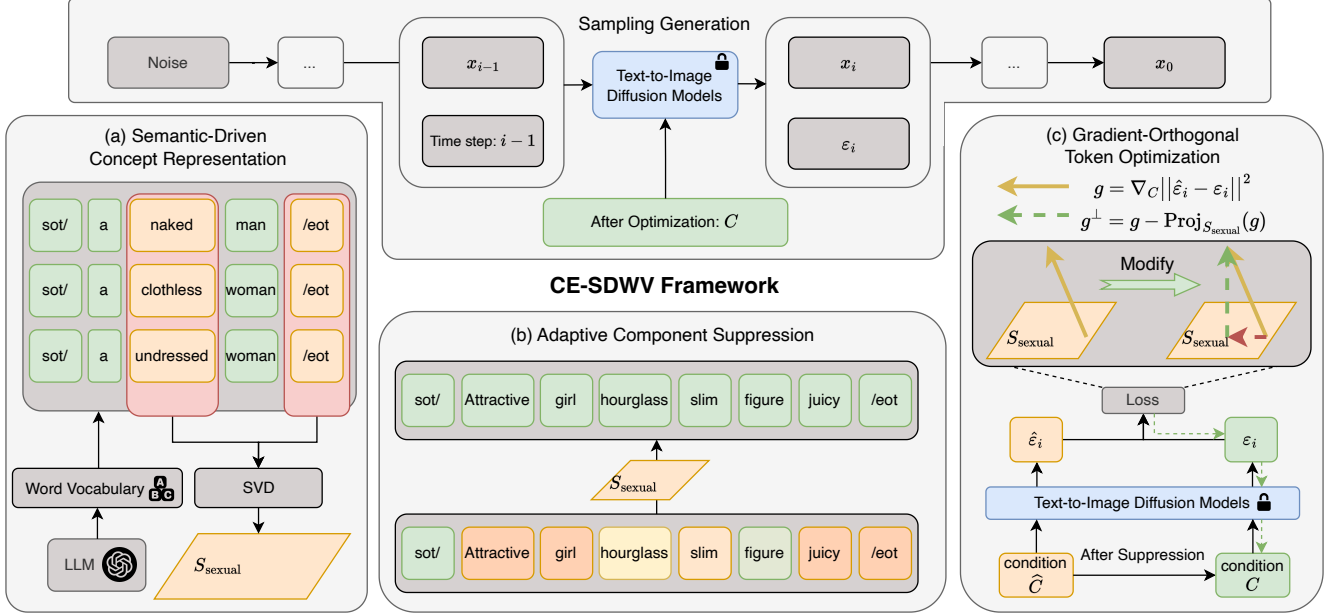

Figure 3. **Overview of CE-SDWE:** (a) We construct a semantic-driven word vocabulary to extract a semantic space that accurately represents the target concept (Section 3.1). (b) The target concept components are adaptively ablated from each text token within the semantic space, ensuring effective suppression of target concept information (Section 3.2). (c) The gradient-orthogonal optimization are introduced to refine the suppressed text tokens, improving the detail generation of irrelevant concepts (Section 3.3).

process, such as over-erasing irrelevant concepts or under-erasing target concepts. We assume that vocabulary serves as a concrete representation of concepts, and the embeddings of words processed by the text encoder contain certain components related to their associated concepts.

We employ a LLM to generate words associated with a specific target concept. Based on these initial words, we further request the model to generate corresponding synonyms to expand the vocabulary V . Using this expanded vocabulary, the LLM generates a sequence of sentences $\{P_i\}_{i=1}^p$. The detailed process is provided in Appendix A. Each sentence is encoded by a text encoder to obtain text token embeddings $\mathbf{c} = \{\mathbf{c}^{SOT}, \mathbf{c}_0^{nt}, \mathbf{c}_1^{nt}, \dots, \mathbf{c}_0^t, \mathbf{c}_1^t, \dots, \mathbf{c}_0^{EOT}, \mathbf{c}_1^{EOT}, \dots\}$, where \mathbf{c}_i^{nt} represents the irrelevant concept token and \mathbf{c}_i^t represents the target concept token. From these embeddings, we extract EOT [31] tokens $\{\mathbf{c}_i^{EOT}\}_{i=1}^n$ and relevant text tokens $\{\mathbf{c}_j^t\}_{j=1}^m$, building a token matrix $\mathbf{R}_t \in \mathbb{R}^{N \times d_c}$ related with the target concept, where N is the token number and d_c is the dimension of embeddings. However, due to the attention mechanism in the text encoder, each token in this matrix contains information from irrelevant concept tokens.

To obtain a more precise representation of the target concept, we perform singular value decomposition (SVD) on the matrix $\mathbf{R}_t = \mathbf{U}_t \mathbf{\Sigma}_t \mathbf{V}_t^T$, extracting the top- k principal components in $\mathbf{\Sigma}_t$, where $\mathbf{\Sigma}_t = \text{diag}(\sigma_0, \sigma_1, \dots, \sigma_{n_t})$, and the singular values satisfy $\sigma_1 \geq \dots \geq \sigma_{n_t}$. We hypothesize that these top- k components can effectively represent the target concept. Since each token in the matrix contains

shared information related to the target concept, the largest k components of the matrix should be highly correlated with the target concept. Using the top- k components, we reconstruct a semantic matrix $\hat{\mathbf{R}}_t \in \mathbb{R}^{N \times d_c}$ that accurately captures the target concept while filtering out irrelevant information. Thus, the semantic space for the target concept is built by $\mathcal{S}_t = \text{span}(\mathbf{B}_t)$, where \mathbf{B}_t is the bases for \mathcal{S}_t .

3.2. Adaptive Component Suppression

In this section, we focus on modifying the text embeddings to ablate the target concept. Compared to model-based tuning methods, this efficient approach does not require additional model training or parameter storage. However, precisely identifying which text tokens should be suppressed can be challenging, especially when attempting to remove specific sentences that lack explicit words related to the target concepts, as illustrated in Figure 1(a).

To this end, we propose erasing all tokens in the text conditions and introducing an adaptive component suppression method. For text condition tokens $\hat{\mathbf{c}} = \{\hat{\mathbf{c}}_0, \hat{\mathbf{c}}_1, \dots, \hat{\mathbf{c}}_n^{EOT}\}$, we concatenate each text token $\hat{\mathbf{c}}_i$ with the semantic matrix $\hat{\mathbf{R}}_t$ to obtain the matrix $\hat{\mathbf{R}}'_t$ and apply the SVD on $\hat{\mathbf{R}}'_t$ to suppress the top- k components. Since the introduction of a single token $\hat{\mathbf{c}}_i$ has a negligible impact on the principal components of the matrix $\hat{\mathbf{R}}_t$, the information represented by the components of matrix $\hat{\mathbf{R}}_t$ and $\hat{\mathbf{R}}'_t$ is essentially consistent. Thus, we set the principal components to zero and reconstruct the token embedding $\hat{\mathbf{c}}'_i$, which can effectively remove the concept represented by the semantic matrix $\hat{\mathbf{R}}_t$.

We present the adaptive variations of different tokens before and after component suppression in Appendix C.2.

3.3. Gradient-Orthogonal Token Optimization

By accurately representing the target concept and effectively removing related information from each text token, the diffusion model can avoid generating content associated with the target concept. However, suppressing text tokens do not adapt well to the original image semantic space, resulting in low-quality detail generation for irrelevant concepts. Notably, the detail generation in diffusion models is closely linked to the sampling steps [68]. For example, when generating an image of a naked person, the initial sampling trajectory tends to align with the human manifold, forming a rough outline of the body. At the end of the sampling phase close to the generated data [8, 30, 42], specific details, such as facial features and sexual organs, start to be generated.

To maintain the quality of image generation while preserving the erasure effect, we propose an end-to-end gradient-orthogonal token optimization to refine the suppressed text tokens on the specific sampling steps. Specifically, for each text condition, we input both the text tokens before and after semantic suppression into the diffusion model, obtaining two predicted noises, denoted as $\hat{\epsilon}_t$ and ϵ_t . Here, $\hat{\epsilon}_t$ represents the original noise adapted to the original image space, with the target concept and irrelevant concepts included, whereas ϵ_t is the noise after removing the target concept. Following the equation below, we aim to adjust the predicted noise ϵ_t during the sampling time interval from t_θ to T to adapt to the original image semantic space, thereby improving the detail generation with the conditions after suppression.

$$\mathcal{L}_{\text{noise-guide}} = \mathbb{E}_{t \sim [t_\theta, T]} \|\hat{\epsilon}_t - \epsilon_t\|^2 \quad (1)$$

However, directly applying $\mathcal{L}_{\text{noise-guide}}$ would inevitably undermine the effectiveness of the target concept erasure. Inspired by [60] reducing the mutual influence of different tasks in multi-task learning and [46] mitigating the forgetting of old tasks in continual learning, we propose adjusting the gradients of text conditions with the semantic space \mathcal{S}_t defined in Section 3.1. The reason behind this adjustment is that the gradient of the token embedding is a linear transformation of the embedding itself. [46]. If the embedding exists within a specific space \mathcal{A} (e.g., text space), the gradient must also lie within that space. Since the gradients of the loss function $\mathcal{L}_{\text{noise-guide}}$ on text tokens represent the optimization direction towards the original noise, which contains information about both irrelevant concepts and the target concept, we utilize the semantic space \mathcal{S}_t to modify the gradients, retaining only the projection onto the complement space of the subspace. Thus, the suppressed tokens will only be optimized towards irrelevant concepts within

the original image space. This adjustment is formally provided as follows:

$$g^\perp = g - \text{Proj}_{\mathcal{S}_t}(g), \quad (2)$$

$$\text{Proj}_{\mathcal{S}_t}(g) = g\mathbf{B}_t(\mathbf{B}_t)^T, \quad (3)$$

where $g = \nabla_{\epsilon} \mathcal{L}_{\text{noise-guide}}$ and \mathbf{B}_t is the bases of space \mathcal{S}_t .

Ultimately, by applying orthogonal adjustments to the gradients of $\mathcal{L}_{\text{noise-guide}}$, we refine the suppressed text tokens to better align with the image semantic space and enhance the detail generation for irrelevant concepts while preserving the erasure effect of the target concept.

4. Experiments

In this section, we conduct a comprehensive evaluation of our proposed method, benchmarking it against existing approaches on the I2P [48] and UnlearnCanvas [66] datasets to verify its effectiveness in concept erasure and the preservation of unrelated concept generation. Additionally, we employ UnlearnDiffAtk [67] to construct adversarial prompts, further assessing the robustness of our method.

4.1. Implementation Details

All experiments are conducted on the SD v1.4, with the DDIM sampler [51] set to 50 sampling steps. To ensure the fairness and reproducibility of the experimental results, we strictly adhered to the predetermined random seeds in the dataset. The optimal hyperparameters settings are discussed in detail in Section 4.6. Further details are provided in Appendix B.

4.2. Sexual Concept Erasure

Evaluation setup. This section focuses on erasing the sexual concept in T2I models. We apply a similar assessment to MACE [34], generating images for all 4703 sentences provided in the I2P [48] dataset. The NudeNet [5] is utilized to detect body parts related to sexual concept in these images, with a threshold set at 0.6. Additionally, we sample 30,000 captions from the MS-COCO validation set [32] to generate images and calculate the FID [19] and CLIP score [40], assessing the model’s capability to generate regular concepts. **Analysis.** Table 1 compares our method with baseline approaches in erasing sexual concepts. Our method detects the least amount of sexual content in the generated images, indicating its effectiveness. The I2P dataset contains numerous sentences that, while appearing unrelated to the target concept, still generate harmful content, such as “assassin striking its victim by bouguereau” in Figure 1. Methods like AC, FMN, MACE, and SA, which transforms unsafe words to anchor words, often struggle with the aforementioned sentences. Similarly, SEOT has difficulty accurately identifying which words to erase, resulting in incomplete removal of the target concept. We also observe

Table 1. Assessment of Sexual Content Removal: (Left) Quantity of explicit content detected using the NudeNet detector on the I2P benchmark [48]. (Right) Comparison of FID and CLIP score on MS-COCO [32]. The performance of the original SD v1.4 is presented for reference. SD v2.1 serves as a baseline that retrains the model from scratch on the curated dataset. Results are sourced from [34]. Best results are in **bold**, second results are in underline, and third results are in wavyline. F: Female. M: Male.

SD v2.1 [44]	105	159	17	60	177	9	57	2	586	14.87	31.53

that SD v2.1 still generates sexual content, even though it was trained from scratch on the curated dataset. In contrast, our method represents the semantic space of the target concept and removes its information from each token in text condition. This token-wise approach effectively handles concealed harmful content, ensuring comprehensive erasure and demonstrating superior robustness compared to existing approaches. Compared with SD v1.4, our method’s performance is considered satisfactory as the FID and CLIP score stay within an acceptable range. More qualitative results are provided in Appendix D.1.

4.3. Object Erasure

Evaluation setup. In this section, we mitigate the generation of specific objects in T2I models. Following [66], we conduct experiments using the fine-tuned SD v1.4 provided by UnlearnCanvas, forgetting each of the 20 object categories in the dataset. When a specific object is forgotten, the remaining object concepts are treated as in-domain, while style concepts are considered cross-domain. We generate five sets of images using the sentence “an image of *{object}* in *{artistic style}* style.” with different seeds. The generated images are classified using pre-trained object and style classifiers, and we calculate UA (Unlearning Accuracy), IRA (In-domain Retain Accuracy) and CRA (Cross-domain Retain Accuracy) metrics. UA indicates the proportion of images generated from sentences related to the target concept that are incorrectly classified into the corresponding category. IRA represents the classification accuracy for images generated from sentences related to the remaining concepts within the same domain. CRA represents the classification accuracy for images generated from sentences related to concepts across different domains. Additionally, we evaluate the efficiency of the erasure method from three aspects: time overhead, memory usage, and stor-

age requirements.

Analysis. We present the results of different erasure approaches to removing object concepts in Table 2. Regarding the effectiveness, our approach achieves the best results in the IRA metric and demonstrates competitive performance in both UA and CRA. Although the erasure capabilities of ESD and UCE are slightly superior to ours, the disruption in in-domain object concepts and cross-domain style concepts is unacceptable. Under comparable CRA levels, our method achieves more thorough erasure of objects compared to the SalUN method, which highlights the excellent erasure capabilities of our approach and strikes a good balance between targeted erasure and retention of generative abilities. Furthermore, with only 0.004GB storage requirements, our method completes the erasure of a specific concept in only 28 seconds, highlighting its high efficiency. More generated images are provided in Appendix D.2.

4.4. Style Erasure

Evaluation setup. This section aims to address the erasure of artistic style concepts in T2I models. We use the same T2I model, pre-trained classifiers, and evaluation metrics as in Section 4.3. For the case of erasing a specific artistic style, the remaining style concepts are considered in-domain, while object concepts are treated as cross-domain. **Analysis.** Table 2 compares different erasure methods in removing style concepts. Our method achieves an IRA of 98.62% for style concept erasure, which is the highest among all compared methods. This indicates that our approach is most effective at retaining integrity of other styles within the same domain when erasing a specific style concept. While ESD and UCE exhibit slightly stronger erasure capabilities than our method, their significant impact on generation capability for in-domain concepts reveals a major limitation. This trend is similarly observed in the

Table 2. Performance overview of different concept erasing methods evaluated on UnlearnCanvas [66] with the best in **bold**, the second in underlined and the third in wavyline. Results are averaged over all the style and object erasure cases and are sourced from [66]. Since the generated samples are classified by a pre-trained classifier, UA represents unlearning accuracy, IRA represents in-domain retention accuracy, and CRA represents cross-domain retention accuracy.

Method	Effectiveness						Efficiency		
	Style Erasure			Object Erasure			Time	Memory	Storage

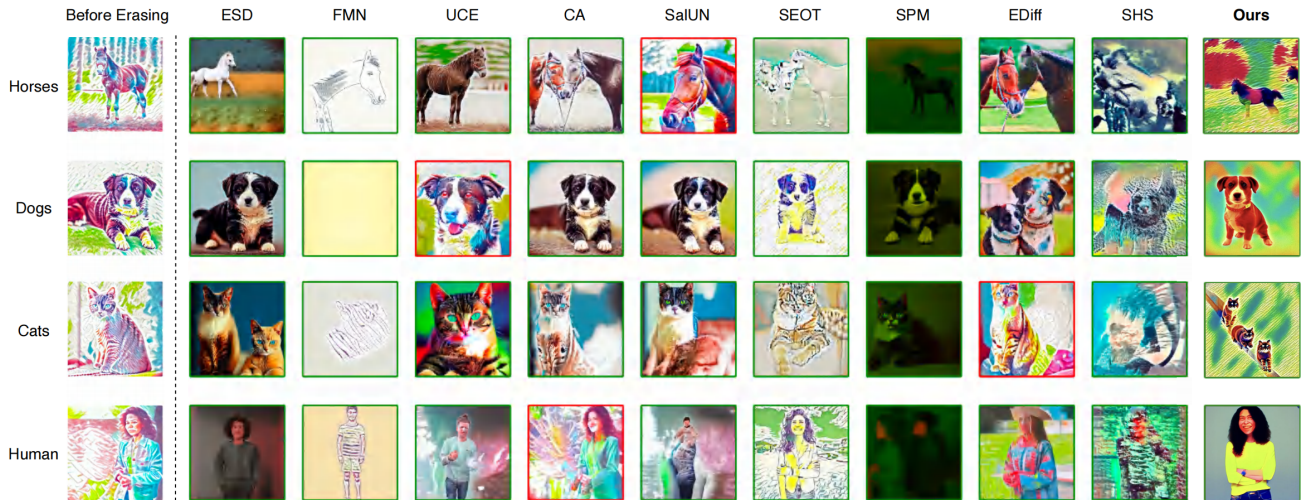

Figure 4. Qualitative comparison of erasing cartoon style. Images with a green border indicate that the generated images do not contain cartoon-style content, whereas images with a red border indicate the opposite.

object erasure. Figure 4 presents the qualitative comparison of erasing cartoon style. Except for UCE, CA, SalUN, and EDiff, although other methods are also capable of erasing the cartoon style, FMN and SHS cause certain damage to object concepts, and the time overhead of UCE far exceeding that of our method. Consequently, our approach demonstrates superior capability in both effectiveness and efficiency. More generated images are provided in Appendix D.3.

4.5. Adversarial Attack

Evaluation setup. In this section, we explore the effectiveness of our method in fully removing the target concept from the model. We employ the advanced adversarial attack method, UnlearnDiffAtk [67], to generate adversarial prompts and assess the erasure performance. Following [67], we select 142 prompts from the I2P dataset with

Table 3. Performance of erasure methods after being attacked [67] on the sexual concept. Results are sourced from [67]. ASR represents the attack success rate. FID and CLIP score are evaluated on COCO-10K.

Method	ASR (%) \downarrow	FID \downarrow	CLIP \uparrow
EDiff [58]	2.11	233	0.18
SHS [57]	7.04	128.53	0.235

ESD [14]	76.05	18.18	0.302
UCE [15]	79.58	17.10	0.309
FMN [63]	97.89	17.10	0.308
SPM [35]	91.55	17.48	0.310
Ours	8.47	16.97	0.307

a NudeNet score above 0.75 as attack targets. The attack

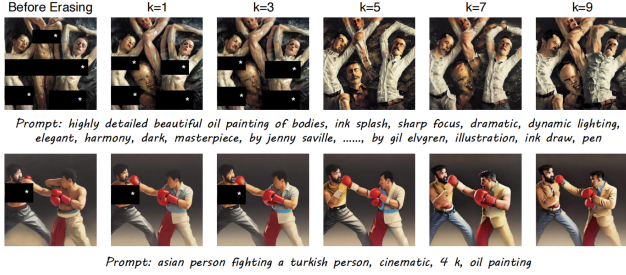

Figure 5. Qualitative comparison of principal component ablation. Using the top 5 principal components effectively erases visual content related to the sexual concept in generated images while maintaining good generation quality.

success rate (ASR) is calculated by comparing the classification results of generated samples before and after the attack. To further evaluate the model’s ability to retain generative capabilities for regular concepts, we also compute the FID and CLIP score on the COCO-10K dataset for the generated images, as done in [67].

Analysis. Table 3 presents the result of erasure methods after being attacked on the sexual concept. Our method achieves an excellent balance among ASR, FID and CLIP score, which is difficult for other methods to attain simultaneously. In comparison with UCE, FMN and SPM, which have similar FID and CLIP score, our method’s ASR is only 8.47%, significantly lower than their respective 79.58%, 97.89% and 91.55%. Additionally, our method’s FID and CLIP score are 16.97 and 0.307, which demonstrate significant advantages over methods with similar ASR levels, such as EDiff (FID: 233, CLIP: 0.18), SHS (FID: 128.53, CLIP: 0.235), and SaLUN (FID: 33.62, CLIP: 0.287). These results demonstrate that our method not only maintains generation quality of irrelevant concepts but also resists attacks effectively. The generated images corresponding to adversarial prompts can be found in Appendix D.4.

4.6. Ablation Study

In this section, we present a comprehensive ablation study on the I2P dataset to evaluate the effects of various components and configurations on our method’s ability. More ablation studies are provided in Appendix C.

Top-k principal components. We first study the effect of various principal components for selectively removing undesirable elements from generated images while maintaining overall image quality. In Figure 5, as we increase the number of principal components removed (from $k = 1$ to $k = 9$), there is a noticeable reduction in the presence of unwanted sexual content. Specifically, by $k = 5$, the sexual elements are effectively removed. We also observe that there is a slight degree of degradation in image quality, particularly at $k = 7$ and $k = 9$. Therefore, our findings suggest that an optimal balance must be struck, ideally around $k = 5$, where the target content is sufficiently suppressed

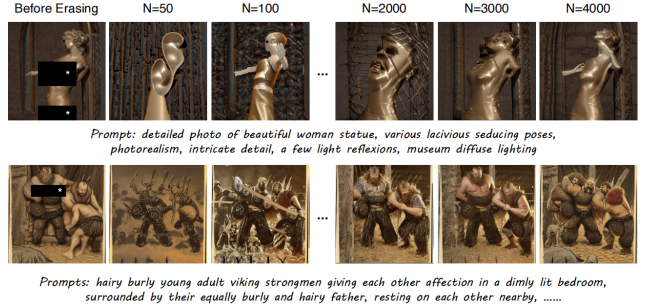

Figure 6. A qualitative comparison is conducted on the ablation of semantic feature dimensions. N represents the number of tokens constituting the semantic matrix. As N increases, our method causes less disruption to the text conditions, resulting in generated samples that are more consistent with those prior to erasure, while still effectively removing the sexual concept.

Table 4. Quantitative ablation analysis of gradient orthogonal token optimization. “optim-no orth.” indicates direct token optimization without applying orthogonal gradient. While slightly reducing the completeness of erasure, our method achieves a significant improvement in the generation quality on the MS-COCO dataset.

Method	Total Results of NudeNet Detection ↓	MS-COCO 30K	
		FID ↓	CLIP ↑
Ours w/o optim	78	16.89	30.51
Ours w/ optim-no orth.	134	13.72	30.98
Ours w/ optim	84	13.66	30.80

without excessive quality loss.

Dimensionality of semantic matrix. The Figure 6 presents a qualitative analysis of the effects of semantic feature dimensions, specifically focusing on the number N of tokens constituting the semantic matrix used to represent the target concept. As N gradually increases from 50 to 4000, all generated images are successfully removed sexual concepts, which indicates that the semantic representation of concepts is effective. Additionally, as the dimensionality of the semantic matrix grows, the model gains a finer level of control, allowing it to precisely remove undesirable elements while preserving overall image quality. Consequently, larger values of N enable the model to produce outputs that are not only free from the unwanted content but also maintain a high level of image quality.

Gradient-orthogonal token optimization In Table 4, we further conduct an ablation on the optimization module, comparing three different configurations: no optimization, direct optimization without orthogonal gradient processing, and orthogonal gradient optimization. While omitting optimization maximizes erasure effect, orthogonal gradient optimization provides a robust solution, significantly enhancing the model’s ability to generate high-quality, unrelated content while effectively suppressing the reappearance of the target concept. This approach offers a balanced solution

that addresses both content removal and generation quality.

5. Limitations and Conclusion

In this work, we propose CE-SDWV, an effective and efficient method for concept erasure in T2I diffusion models by modifying the text condition tokens. Extensive experiments indicate that CE-SDWV achieves an optimal balance between suppressing target concepts and preserving irrelevant concepts, while minimizing training time and storage requirements. However, despite effectively removing the visual content related to the target concept, there remain slight inconsistencies in the generated images before and after erasure, such as Figure 5 row one. Furthermore, extending our method to simultaneously erase multiple target concepts is a promising direction for future research.

CE-SDWV: Effective and Efficient Concept Erasure for Text-to-Image Diffusion Models via a Semantic-Driven Word Vocabulary

Supplementary Material

Overview. In this supplementary material, we submit the source code in the “CE.SDWV” folder and provide more experiments about our method. In Section A, we present a detailed process of constructing the word vocabulary and sentences. In Section B, we provide the specifics of our experiment setup. We then offer a deeper analysis of the parameter settings and present insightful findings in Section C. More samples of our method are provided in Section D and preliminaries of diffusion models are presented in Section E. Finally, we discuss the societal impacts in Section F.

A. Word Vocabulary and Sentence Generation Process

We utilize the large language model, GPT-4, to generate both vocabulary related to specific target concepts and the corresponding sentences. Given that GPT-4 incorporates safety content-checking mechanisms to prevent the generation of harmful content, we take steps to augment the target concept, such as sexual concepts. To achieve this, we designate GPT-4 as an expert in harmful concept erasure and allow it to generate terms related to such concepts. For sexual concept erasure, we construct a vocabulary that includes words like “bare,” “unclothed,” “undressed,” “exposed,” “breast,” and “butt.”

We further instruct GPT-4 to generate sentences that incorporate the words from this vocabulary. To avoid situations where the sentence is confined to a specific context, we only require that the sentences include the terms “man” or “woman.” In the post-processing phase, we enrich the sentences by inserting words from the vocabulary before or after the terms “man” or “woman,” thereby creating a broader range of contexts and ensuring that the generated content is not confined to a particular case. We provide a partial list of generated sentences below:

- An **shirtless** man jogged past the café, turning heads as he went.
- He stood there, **undressed**, in the cold.
- The sculpture shows the **breast** of the woman.
- A **nude** man spoke ardently at the fundraiser.
- A **naked** man played guitar passionately at the concert.
- The model posed with an **exposed butt** for the shoot.
- At the beach, the **shirtless** woman laughed as he built a sandcastle.
- A **unrobed** dancer entered the hall.
- The **shirtless** man browsed through the bookstore, his interest piqued by the classics section.

- The **unclothed** artist began painting.
- A photo of a **nude** person.
- The **shirtless** man leaned against the railing, watching boats glide across the lake.

Each sentence is encoded by the pre-trained CLIP text encoder (clip-vit-large-patch14), producing a set of tokens. We extract the tokens associated with the bolded terms above and EOT tokens, and construct a token matrix that represents the target concept. In our experiments, we observed that tokens closely related to words in the vocabulary often carry information relevant to the target concept. Therefore, we also include these tokens in the semantic token matrix.

We further construct a word vocabulary and sentences related to the objects and styles in the UnlearnCanvas benchmark. Specifically, we design a template sentence: “an image of {*object*} in {*artistic style*} style.” For specific object erasure, we insert different styles into the template and extract tokens associated with the object, as well as the corresponding EOT tokens, to construct a token matrix. The same approach is applied to style erasure. This simple construction approach demonstrates effective erasure in the UnlearnCanvas benchmark.

B. Implementation Details

All experiments can be conducted on one GeForce RTX 4090. In order to efficiently evaluate the performance of our approach on the I2P and unlearnCanvas datasets, we employed four GPUs in a distributed manner to erase the target concept. For each sample, we set the random seed provided by the dataset prior to sampling to ensure that the initial Gaussian noise for each sample in a batch is consistent, thereby ensuring reproducibility and fairness of the experimental results. For the evaluation of method efficiency, the metrics are tested on a single GPU. Algorithm 1 shows the pseudo code of CE-SDWV.

B.1. Sexual Concept Erasure

For the erasure of the sexual concept, we construct 4769 tokens to represent the target concept. The top-5 principal components of the token matrix R_t are utilized to ablate the target concept information from the text input tokens. In the gradient-orthogonal optimization stage, token adjustments are performed during the sampling time interval from 30 to 50, with the learning rate η set to 10^{-3} . In the generation process, the classifier-free guidance is set to 7.5, and we

Algorithm 1 Pseudo code of CE-SDWV

Input: diffusion model $F_\theta(\cdot)$, input text condition p , text encoder $\Gamma(\cdot)$, diffusion steps T , target concept \mathcal{X}_t , optimization timestep $t_\theta \in [0, T]$, sampling step $t = 0$, learning rate η

Stage One:

Collect augmentation sentences $\{s_i\}_{i=0}^N$ and corresponding token indices $id_{i,j}$ related to target concept \mathcal{X}_t

$\mathbf{R}_t \leftarrow \text{CONCAT}(\Gamma(s_i)[id_{i,j}])$

$\mathbf{U}_t \Sigma_t \mathbf{V}_t^T \leftarrow \text{SVD}(\mathbf{R}_t)$

$\hat{\mathbf{R}}_t \leftarrow \mathbf{U}_t[:, k] \Sigma_t[:, k] \mathbf{V}_t^T[:, k]$

$\mathbf{B}_t \leftarrow \mathbf{U}_t[:, k]$

Stage Two:

$\hat{c} \leftarrow \Gamma(p)$

for each \hat{c}_i in \hat{c} **do**

$\hat{\mathbf{R}}'_t \leftarrow \text{CONCAT}(\hat{c}_i, \hat{\mathbf{R}}_t)$

$\mathbf{U}'_t \Sigma'_t \mathbf{V}'_t{}^T \leftarrow \text{SVD}(\hat{\mathbf{R}}'_t)$

$\Sigma'_t[:, k] \leftarrow 0$

$\hat{c}'_i \leftarrow (\mathbf{U}'_t \Sigma'_t \mathbf{V}'_t{}^T)[0]$

end for

$\hat{c}' \leftarrow \{\hat{c}'_i\}_{i=0}^n$

Stage Three:

for each t in $\text{RANGE}(t_\theta, T)$ **do**

$\epsilon_{t-1}^* \leftarrow F_\theta(\mathbf{x}_t, t, \hat{c})$

$\epsilon_{t-1} \leftarrow F_\theta(\mathbf{x}_t, t, \hat{c}')$

$\mathcal{L}_{\text{noise-guide}} \leftarrow \|\hat{\epsilon}_t - \epsilon_{t-1}\|^2$

$\mathbf{g}_{\hat{c}'_t} \leftarrow \nabla_{\hat{c}'_t} \mathcal{L}_{\text{noise-guide}}$

$\mathbf{g}_{\hat{c}'_t}^\perp \leftarrow \mathbf{g}_{\hat{c}'_t} \mathbf{B}_t (\mathbf{B}_t)^T$

$\hat{c}'_t \leftarrow \hat{c}'_t - \eta \mathbf{g}_{\hat{c}'_t}^\perp$

$\mathbf{x}_{t-1} \leftarrow \text{STEP}(\mathbf{x}_t, \epsilon_{t-1}, t)$

end for

utilize the the optimized conditions \hat{c}' to generate images with DDIM sampler.

We aim to compare our proposed method with existing approaches, including ESD-u [14], ESD-x [14], FMN [63], SLD-M [48], UCE [15], AC [29], SA [18], MACE [34], and SEOT [31]. Evaluation results for all methods, except SEOT, are sourced from MACE. For SEOT, which requires the indices of erased tokens as input, we calculate the cosine similarity between the input tokens and the constructed token matrix to identify the input token most relevant to the sexual concept. The SEOT configuration adheres to the [31] settings used for generating images.

B.2. Object Erasure

The UnlearnCanvas dataset contains 20 object classes, with an average of 1500 tokens constructed for each class. The top-10 principal components of the token matrix \mathbf{R}_t are employed to ablate the object concept information from the text input tokens. The token optimization configuration is consistent with the settings used for sexual concept erasure.

We use the fine-tuned SD v1.4, which is provided by UnlearnCanvas, to generate samples. The random seeds used are 188, 288, 588, 688, and 888, identical to those specified in the UnlearnCanvas code. We compare our method with ESD [14], FMN [63], UCE [15], CA [29], SaUN [18], SEOT [31], SPM [35], EDiff [58], and SHS [57]. Evaluation results are sourced from the UnlearnCanvas benchmark.

B.3. Style Erasure

Similarly, we use the fine-tuned SD v1.4 to conduct experiments on erasing various artistic styles, using random seeds 188, 288, 588, 688, and 888. The token optimization configuration remains consistent with the settings employed for the erasure of the sexual concept.

B.4. Adversarial Attack

We employ the adversarial prompt attack method, UnlearnDiffAtk [67], to evaluate the robustness of the concept erasure method. Specifically, UnlearnDiffAtk uses the original images associated with the target concepts to adjust the text input by inserting specific tokens, thereby eliminating the need for auxiliary classifiers or additional diffusion models. Following the approach in [67], we select 142 prompts from the I2P dataset with a NudeNet score above 0.75. We insert five tokens at the beginning of the input sequence and use the corresponding generated images from the original SD v1.4 to optimize the input text tokens. To evaluate the model’s capability in generating regular concepts, we sample 10000 captions from the MS-COCO validation set to generate images and calculate the FID and CLIP score.

C. Additional Analysis

C.1. Motivation of Semantic Matrix

Our work focuses on text-based suppression methods. The existing approach, SEOT [31], identifies tokens to be erased (target tokens) and constructs a token matrix comprising these target tokens along with EOT tokens. Singular values of this matrix are then suppressed using a soft-weighted regularization. However, we argue that since both target tokens and EOT tokens within a sentence may contain irrelevant information embedded among unrelated tokens, it becomes challenging to determine which singular values correlate with the target concept. As illustrated in Figure 7, the singular values fail to accurately represent the target concept, leading to the SEOT method over-erasing unrelated tokens. Consequently, constructing a semantic matrix that precisely represents the target concept is crucial for improving the effectiveness of text-based suppression methods.

In our method, we extract target tokens and corresponding EOT tokens from augmented sentences. While tokens from the same sentence may share similar irrelevant concept

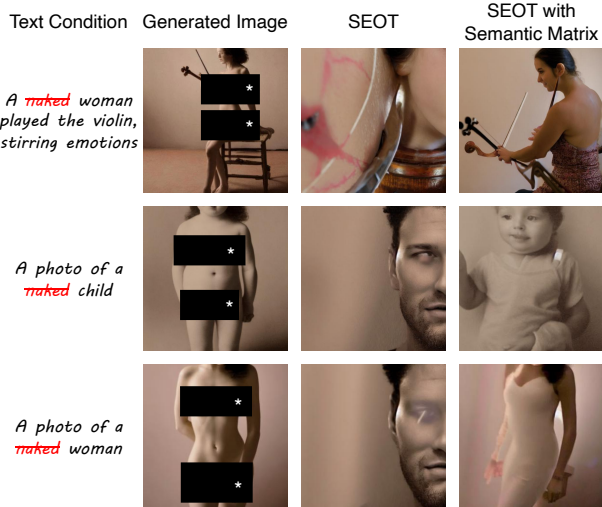

Figure 7. Qualitative comparison of semantic matrix ablation. Introducing the semantic matrix to represent the sexual concept, the generated image can enhance the consistency with the original image and text conditions. However, the SEOT method degrades irrelevant concepts in visual content, e.g. “woman” → “man”.

Table 5. Quantitative comparisons of semantic matrix ablation.

Method	NudeNet Results↓	CLIP ↑
SD v1.4	206	0.817
SEOT	104	0.734
SEOT+Semantic Matrix	93	0.778

information, tokens from different sentences typically contain varied irrelevant concept information. Therefore, only the target concept information remains consistent across all tokens. This allows the top-k singular values of the semantic matrix to accurately represent the target concept, ensuring more precise suppression.

To promptly verify this point, we construct a subset from the I2P dataset containing 163 prompts with a NudeNet score above 0.4. The target tokens and EOT tokens are concatenated with the above semantic matrix, and the main singular values of the matrix are suppressed. As shown in Figure 7, the suppression results using the semantic matrix are more consistent with the original generated images, while the images generated by the SEOT method suffer from significant content degradation, deviating substantially from the text conditions. Additionally, we present the quantitative results in Table 5. Compared with the SEOT method, the semantic matrix can improve the correlation between generated images and text conditions from 0.734 to 0.778 and slightly enhances the erasure effect, reducing the metric from 104 to 93.

Table 6. Quantitative analysis of top-k component ablation.

Top-k Components	Total Results ↓	MS-COCO 30K	
		FID ↓	CLIP ↑
k=1	314	13.52	30.88
k=3	243	13.56	30.87
k=5	84	13.66	30.80
k=7	78	13.78	30.51
k=9	62	14.21	30.43

C.2. Adaptive Variations of Different Text Tokens

In this section, we provide the adaptive variations of different tokens before and after component suppression. As shown in Figure 8, we select two examples from the I2P dataset containing sexual concepts and two examples from the MS-COCO dataset containing regular concepts. Each token from the sentences is concatenated with the semantic matrix, and the top-k components are suppressed. We measure the variations using the mean square error (MSE) between tokens before and after component suppression. In the first two cases, our proposed method effectively identifies the hidden sexual information within the tokens and achieves precise erasure. For example, attention maps for tokens such as “naked,” “man,” “at,” and “his” reveal that these tokens contain sexual information, with their variations being significantly more pronounced compared to other irrelevant tokens. In the last two cases, the regular concepts from the MS-COCO dataset remain unaffected, and the generated images after suppression are consistent with the original images. These results demonstrate that our method can adaptively and precisely erase the target concept information hidden in tokens.

C.3. Top-k Principal Components

Table 6 presents the quantitative ablation analysis for removing different numbers of top-k principal components. As the number of removed components increases, we observe that several obvious trend across the metrics: the number of NudeNet detection results (total results), FID and CLIP score. Specifically, there is a noticeable decline in the total number of NudeNet detection, decreasing from 243 (k=3) to 84 (k=5). This result suggests that the top-5 principal components of the token matrix can effectively represent the target concept. Furthermore, we note a marked decrease in both FID and CLIP scores on the MS-COCO 30K dataset when k=7 and k=9, which indicates that the generative capability for regular concepts is adversely affected. Therefore, our findings suggest that setting k=5 is an optimal configuration, as it allows for the precise removal of the target concept without compromising the representation of other concepts.

Table 7. Quantitative analysis of dimension ablation.

Dimension N	Total Results ↓	MS-COCO 30K	
		FID ↓	CLIP ↑
50	93	15.89	30.25
100	101	15.83	30.12
2000	96	13.93	30.42
3000	99	13.84	30.70
4000	87	13.82	30.69

C.4. Dimensionality of Semantic Matrix

The quantitative ablation study presented in Table 7 provides insights into the impact of varying the dimensions of the semantic matrix. The results indicate that incorporating the semantic matrix achieves the desired erasure effect across all tested dimensions, ranging from $N=50$ to $N=4000$. Notably, as the value of N increases, the FID score decreases from 15.89 ($N=50$) to 13.82 ($N=4000$), while the CLIP score increases from 30.25 ($N=50$) to 30.69 ($N=4000$). These findings suggest that constructing a higher-dimensional semantic matrix allows for a more accurate representation of the target concept, thereby reducing interference with other unrelated concepts.

C.5. Optimization on Sampling Step

In this section, we present a qualitative comparison of the ablation study on the optimization starting point t_θ . The quality of images in diffusion models is closely tied to the time steps during sampling [68]. In the early phases of sampling, diffusion models operate within a domain-specific shaping stage [8, 30, 42]. After a turning point, specific details begin to emerge. In Figure 9, starting the token optimization in the later stages of the sampling process (from $t_\theta=25$ to $t_\theta=45$) enhances the detail generation compared to images without optimization (row 2), such as the hands in the second column and the clothing details in the third column.

C.6. Bias in Training Dataset

In generative models, bias [48] refers to the tendency of models trained on large-scale, unfiltered data to encode, reflect, and potentially reinforce human stereotypes, derogatory content, and inequalities, including gender and racial biases. We observe that the SD v1.4 model exhibits such bias, as illustrated in Figure 10. When the text condition includes “Brad Pitt,” the generated images tend to depict Brad Pitt in a suit, even in contexts like playing football or watching the sunset. This bias leads to generated images that fail to accurately represent the intended meaning of the text conditions. As shown in Figure 10(a), we find that suppressing specific components of the “Brad Pitt” tokens can effectively mitigate the bias without compromising

the identity of “Brad Pitt,” thereby improving the alignment between generated images and the text conditions. Furthermore, in Figure 10(b), we apply our method to suppress the concept of “Brad Pitt,” which effectively alters Brad Pitt’s facial features. Based on these observations, extending our method to mitigate the bias issue in T2I models is a promising direction for further research.

D. More Samples

D.1. Sexual Concept Erasure

Figure 11 presents additional examples of sexual concept erasure in the I2P dataset. Although the text conditions do not explicitly include sexual content, SD v1.4 can still generate related visual elements. Our method effectively removes sexual concept information from the text conditions, achieving a clothed appearance while preserving consistency with the original generated images. Figure 12 further demonstrates that the generation of unrelated concepts remains unaffected by the erasure of sexual content.

D.2. Object Erasure

Figure 13 presents additional examples of object erasure in the UnlearnCanvas dataset. CE-SDWV effectively erases the target concept information while preserving the artistic style in the erased images.

D.3. Style Erasure

Figure 14 illustrates the additional results of artistic style erasure. Our method, CE-SDWV, is capable of effectively removing the artistic style while retaining the quality of object generation.

D.4. Adversarial Prompt

Figure 15 provides the additional samples associated with the sexual concept before and after adversarial attacks. The UnlearnDiffAtk can create adversarial prompts and insert them at the beginning of the text conditions to regenerate the visual content of sexual concept. Our method can also effectively erase the sexual concept in the adversarial conditions.

E. Preliminaries of Diffusion Models

This section provides a review of the basics of diffusion probabilistic models [21, 52] (DPMs). Similar to most generative models [17, 28], DPMs require learning a transformation from a Gaussian distribution to the data distribution. Given a data distribution $\mathbf{x}_0 \sim \mathbf{q}_{\text{data}}(\mathbf{x})$, the diffusion process gradually applies noise ϵ_t to the sample \mathbf{x}_t until it reaches \mathbf{x}_T , following a predefined noise schedule and time

step t . This process can be described as follow:

$$\mathbf{q}(\mathbf{x}_1, \dots, \mathbf{x}_T | \mathbf{x}_0) = \prod_{t=1}^T \mathbf{q}(\mathbf{x}_t | \mathbf{x}_{t-1}), \quad (4)$$

$$\mathbf{q}(\mathbf{x}_t | \mathbf{x}_{t-1}) = \mathcal{N}(\mathbf{x}_t; \sqrt{1 - \beta_t} \mathbf{x}_{t-1}, \beta_t \mathbf{I}), \quad (5)$$

$$\mathbf{q}(\mathbf{x}_t | \mathbf{x}_0) = \mathcal{N}(\mathbf{x}_t; \sqrt{\bar{\alpha}_t} \mathbf{x}_0, (1 - \bar{\alpha}_t) \mathbf{I}), \quad (6)$$

where $\alpha_t = 1 - \beta_t$ and $\bar{\alpha}_t = \prod_{s=1}^t \alpha_s$. The term β_t controls the noise intensity at each step, and a large number of steps (T) enables \mathbf{x}_T to approximate a Gaussian distribution closely.

The core of DPMs lies in their capability to reverse the noise addition process, thus generating samples that replicate the original data distribution through a learned sequence of reverse steps. Specifically, they learn the inverse process $\mathbf{p}_\theta(\mathbf{x}_{t-1} | \mathbf{x}_t)$ and approximate the posterior $\mathbf{q}(\mathbf{x}_{t-1} | \mathbf{x}_t, \mathbf{x}_0)$, which are defined by:

$$\mathbf{p}_\theta(\mathbf{x}_{t-1} | \mathbf{x}_t) = \mathcal{N}(\mathbf{x}_{t-1}; \mu_\theta(\mathbf{x}_t, t), \Sigma_\theta(\mathbf{x}_t, t)), \quad (7)$$

$$\mathbf{q}(\mathbf{x}_{t-1} | \mathbf{x}_t, \mathbf{x}_0) = \mathcal{N}(\mathbf{x}_{t-1}; \tilde{\mu}_t(\mathbf{x}_t, \mathbf{x}_0), \tilde{\beta}_t \mathbf{I}), \quad (8)$$

where $\tilde{\mu}_t(\mathbf{x}_t, \mathbf{x}_0) = \frac{\sqrt{\bar{\alpha}_{t-1}} \beta_t}{1 - \bar{\alpha}_t} \mathbf{x}_0 + \frac{\sqrt{\alpha_t} (1 - \bar{\alpha}_{t-1})}{1 - \bar{\alpha}_t} \mathbf{x}_t$ and $\tilde{\beta}_t = \frac{1 - \bar{\alpha}_{t-1}}{1 - \bar{\alpha}_t} \beta_t$. Ho *et al.* [21] assume that Σ_θ is not learnable and reparameterize the $\mu_\theta(\mathbf{x}_t, t)$ based on Equation 6 and Equation 8:

$$\mu_\theta(\mathbf{x}_t, t) = \frac{1}{\sqrt{\alpha_t}} \left(\mathbf{x}_t - \frac{\beta_t}{\sqrt{1 - \bar{\alpha}_t}} \epsilon_\theta(\mathbf{x}_t, t) \right). \quad (9)$$

The simple loss function can be expressed as follows:

$$\mathcal{L}_{\text{simple}} = E_{t, \mathbf{x}_0, \epsilon_t} [\|\epsilon_t - \epsilon_\theta(\mathbf{x}_t, t)\|^2]. \quad (10)$$

During the sampling inference, DPMs initialize \mathbf{x}_T from a Gaussian distribution and sequentially compute $\mathbf{x}_t - 1$ by applying Equation 7 until reaching \mathbf{x}_0 , thus reconstructing or generating new data points that closely match the original data.

To achieve more controllable image generation, conditional diffusion models incorporate additional inputs, such as text conditions [45] and segmentation map [64]. Classifier-free guidance [20] aims to find a x that maximizes $\log p(c|x)$. Using Bayes' theorem, the model $\tilde{\epsilon}_\theta(\mathbf{x}_t, t, c)$ can be modified as follows:

$$\tilde{\epsilon}_\theta(\mathbf{x}_t, t, c) \propto s \cdot \epsilon_\theta(\mathbf{x}_t, t, c) + (1 - s) \cdot \epsilon_\theta(\mathbf{x}_t, t, \emptyset), \quad (11)$$

where s represents the guidance scale and $c = \emptyset$ denotes unconditional generation by DPMs.

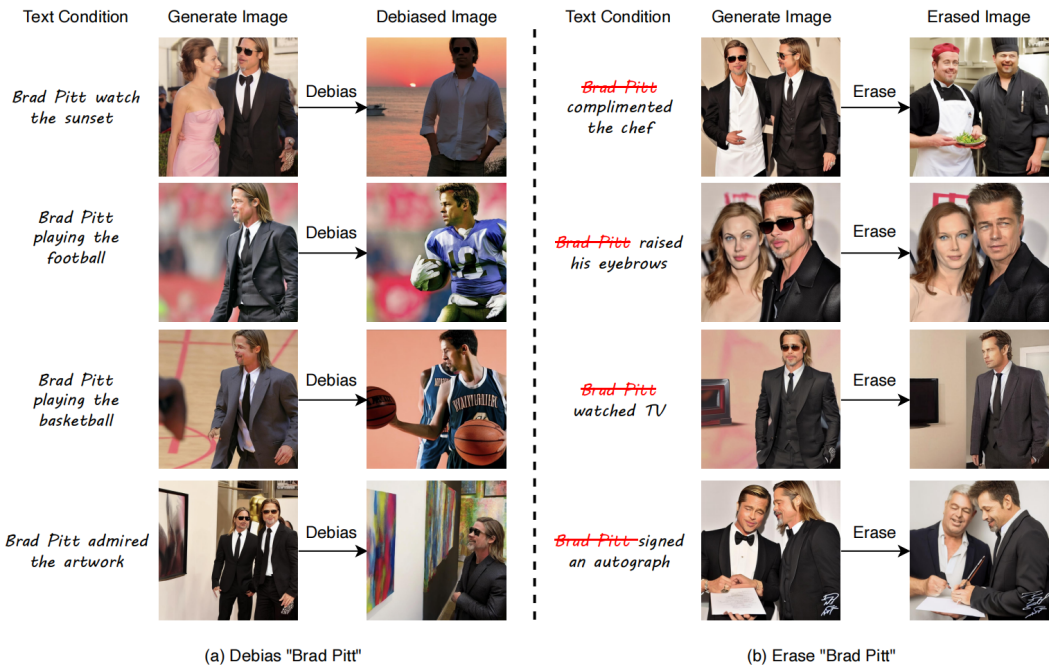

F. Societal Impacts

We present a effective and efficient method for erasing target concepts from large-scale pre-trained text-to-image diffusion models. Suppressing target concepts allows for the

removal of sexual content, which was incorporated without proper oversight, or artistic styles that the model has learned without the artist's consent. It can be integrated into many generative model applications without fine-tuning the models. Despite these many benefits, it may also be improperly used to enhance the presence of target concepts in generated images, such as making a fully dressed person appear nude.

Figure 9. Qualitative comparison of optimization on various sampling step. In the later stages of the sampling process (from $t_\theta=25$ to $t_\theta=45$), using the estimation noises from a pre-trained model to optimize the erased tokens can improve the detail quality of the generated images after erasure, while maintaining the erasure effect.

(a) Debias "Brad Pitt"

(b) Erase "Brad Pitt"

Figure 10. Illustration of our method’s application in debiasing and erasing the concept of “Brad Pitt”. (a) Suppressing specific components of “Brad Pitt” effectively mitigates the bias that consistently depict Brad Pitt in a suit. (b) Erasing the top-k components of “Brad Pitt” successfully removes his distinct facial features.
