Abstract

- **1.** Passive acoustic monitoring (PAM) coupled with artificial intelligence (AI) is becoming an essential tool for biodiversity monitoring. Traditional PAM systems require manual data offloading and impose substantial demands on data storage and computing infrastructure. The combination of on-device AI-based processing and network connectivity enables to analyse data locally and transmit only relevant information, greatly reducing the volume of data requiring storage. However, programming these devices for robust operation is challenging, requiring expertise in embedded systems and software engineering. Despite the increase in AI-based models for bioacoustics, their full potential remains unrealized without accessible tools to deploy them on custom hardware and tailor device behaviour to specific monitoring goals.
- **2.** To address this challenge, we develop acoupi, an opensource Python framework that simplifies the creation and deployment of smart bioacoustic devices. acoupi integrates audio recording, AI-based data processing, data management, and real-time wireless messaging into a unified and configurable framework. By modularising

key elements of the bioacoustic monitoring workflow, acoupi allows users to easily customise, extend, or select specific components to fit their unique monitoring needs.

- **3.** We demonstrate the flexibility of acoupi by integrating two bioacoustic classifiers: BirdNET, for the classification of bird species, and BatDetect2, for the classification of UK bat species. We test the reliability of acoupi over a month-long deployment of two acoupi-powered devices in a UK urban park.
- **4.** acoupi can be deployed on low-cost hardware such as the Raspberry Pi and can be customised for various applications. acoupi standardised framework and simplified tools facilitate the adoption of AI-powered PAM systems for researchers and conservationists. acoupi is on GitHub at <https://github.com/acoupi/acoupi>.

artificial intelligence, biodiversity monitoring, edge computing, passive acoustic monitoring, Raspberry Pi, software

1 | **INTRODUCTION**

With the pressing need for biodiversity conservation, recovery, and management [\(IPBES, 2019\)](#page-12-0), it is essential to develop techniques to scale efforts efficiently [\(Besson et al., 2022\)](#page-10-0). The Kunming-Montreal Global Biodiversity Framework at the 2022 Convention on Biological Diversity Conference (COP15) instituted governments to conserve, manage, and recover natural ecosystems with the goal of protecting 30% of global land and oceans by 2030 [\(Assembly,](#page-10-1) [2015;](#page-10-1) [CBD, 2022\)](#page-11-0). This created incentives and obligations to monitor, measure, and track the state of biodiversity, accentuating the need for scalable, affordable, and accessible tools that provide accurate, comprehensive, and transparent biodiversity observation data [\(Stephenson et al., 2022\)](#page-14-0).

Passive acoustic monitoring (PAM) has emerged as a key approach for conducting biodiversity assessments and generating broader ecosystem analyses [\(Browning et al., 2017;](#page-11-1) [Gibb et al., 2019\)](#page-12-1), while simultaneously providing tools to advance fundamental ecological understanding and conservation science [\(Ross et al., 2023\)](#page-14-1). The decreasing cost and miniaturisation of audio recording devices, such as the open-source AudioMoth [\(Hill et al., 2019\)](#page-12-2), have significantly expanded the capacity for deploying extensive acoustic monitoring networks [\(Sethi et al., 2020\)](#page-14-2). Moreover, the development of AI techniques, including machine learning (ML) and deep learning (DL), to automate the detection and classification of key acoustic signals [\(Kahl et al., 2021;](#page-12-3) [Mac Aodha et al., 2022\)](#page-13-0) enables researchers to obtain insights at the community and species level from diverse data sets [\(Sethi et al., 2024\)](#page-14-3). This has facilitated long-term acoustic studies across scales, from local to continental [\(Roe et al., 2021\)](#page-14-4), and in diverse environments, from urban [\(Fairbrass et al., 2019\)](#page-11-2) to remote and challenging locations [\(Ross et al., 2023\)](#page-14-1), encompassing terrestrial [\(Sugai et al.,](#page-15-0) [2019\)](#page-15-0) and marine species [\(Mooney et al., 2020\)](#page-13-1).

The deployment of PAM systems, however, requires significant human intervention. Frequent site visits are necessary to ensure the correct operation of devices, retrieve audio data, replace storage media, and service batteries [\(Browning et al., 2017\)](#page-11-1). Although stand-alone devices like the AudioMoth [\(Hill et al., 2019\)](#page-12-2) and Solo [\(Whytock and](#page-15-1) [Christie, 2017\)](#page-15-1) offer configurable recording schedule to adjust sampling effort and optimise resource consumption, monthly visits remain common [\(Karlsson et al., 2021\)](#page-12-4). This creates logistical challenges when maintaining PAM systems, more so in fragmented, large, or remote areas. Furthermore, manual retrieval of SD cards and their transport to a central location for analysis [\(Roe et al., 2021;](#page-14-4) [Karlsson et al., 2021\)](#page-12-4) introduce risks of data loss and corruption (Fig. [1A](#page-3-0)). The inherent physical and spatial separation between data collection and processing introduces significant delays in inferring ecological insights and hampers the timely detection of time-sensitive events, such as illegal hunting activity.

Modern networking technologies can significantly accelerate data transfer from field deployments. The combination of cellular, Wi-Fi, or Long-Range Wide-Area Network (LoRaWAN) communication with continuous power sources like solar panels allows longer deployments without intervention [\(Callebaut et al., 2021\)](#page-11-3). Examples include large-scale wildlife monitoring with cellular networks in Borneo [\(Sethi et al., 2020\)](#page-14-2) and Norway [\(Bick et al., 2024\)](#page-10-2), and Wi-Fi network to monitor dolphins in the Mediterranean [\(Brunoldi et al., 2016\)](#page-11-4). However, transferring large audio files, particularly high sample-rate recordings of ultrasonic vocalisations of bats [\(Jones and Holderied, 2007\)](#page-12-5) or rats [\(Coffey et al., 2019\)](#page-11-5), can be challenging due to fluctuating cellular data speeds in areas with suboptimal coverage or the inherent bandwidth limitations of LoRaWAN [\(Adelantado et al., 2017\)](#page-10-3). Critically, storing and processing the transferred recordings is challenging, as large-scale deployments can generate tens of millions of hours of audio, resulting in significant storage and management costs [\(Sethi et al., 2018;](#page-14-5) [Roe et al., 2021\)](#page-14-4). Post-deployment processing with AI-based models requires specialised infrastructure and substantial computing power [\(Sethi et al., 2020;](#page-14-2) [Stowell,](#page-15-2) [2022\)](#page-15-2), potentially limiting the accessibility of acoustic monitoring for teams lacking the resources or expertise.

Edge computing [\(Hua et al., 2023\)](#page-12-6), which involves executing AI-based models on the data-collection devices, offers a promising solution to the challenges of post-deployment processing. This approach reduces computational burdens on centralised infrastructure and enhances system responsiveness [\(Baucas and Spachos, 2020\)](#page-10-4). Early examples include monitoring bats [\(Zualkernan et al., 2021;](#page-15-3) [Gallacher et al., 2021\)](#page-11-6), birds [\(McGuire, 2023;](#page-13-2) [Disabato et al.,](#page-11-7) [2021\)](#page-11-7), wolves [\(Stähli et al., 2022\)](#page-15-4), as well as urban noise levels [\(Baucas and Spachos, 2024\)](#page-10-5) and beehive health [\(Chen](#page-11-8) [et al., 2024\)](#page-11-8). The hardware used in these projects fall broadly into two categories; microcontrollers units (MCUs) and single-board computers (SBCs). MCUs are power efficient but have limited compute, restricting the complexity of embeddable AI-based models [\(Disabato et al., 2021\)](#page-11-7), and require proficiency in low-level programming languages to customise. In contrast, SBCs such as the beginner-friendly and popular Raspberry Pi (RPi) are versatile [\(Jolles, 2021\)](#page-12-7) and support various peripherals and sensors. Additionally, they allow the use of high-level programming languages like Python, a tool increasingly common in ecological research [\(Ulloa et al., 2021;](#page-15-5) [Lapp et al., 2023;](#page-13-3) [Martínez Balvanera](#page-13-4) [et al., 2024\)](#page-13-4). The BirdNET-Pi project [\(McGuire, 2023\)](#page-13-2) illustrates the popularity of setting up RPi-based stations for real-time bird monitoring using the DL model, BirdNET [\(Kahl et al., 2021\)](#page-12-3). However, existing edge computing solutions for biodiversity monitoring often use a rigid software architecture that is tightly coupled to specific hardware and selected AI-based model, limiting adaptability. Developing software to coordinate concurrent recording, processing, and transmission of data presents a technical challenge. Despite the increasing development of AI-based techniques in bioacoustics [\(Höchst et al., 2022\)](#page-12-8), their potential for biodiversity monitoring remains underused without accessible tools for embedding these models within edge devices while meeting specific project requirements [\(Napier et al.,](#page-13-5) [2024\)](#page-13-5).

Here, we develop acoupi, an open-source Python framework that simplifies the creation, configuration, and de-

ployment of devices with on-device processing and network connectivity. Built with a modular approach, acoupi enables users to configure the entire bioacoustic workflow, from audio data collection and on-device AI processing to data management and wireless transfer (Fig. [1B](#page-3-0)). Key features include simplified integration of custom AI-based models, fine-tuning of device behaviour through configuration settings, and reliable deployment on a range of compatible Linux-based SBC devices (Fig. [1C](#page-3-0)). To demonstrate acoupi capabilities, we integrate two bioacoustic DL classifiers: BirdNET [\(Kahl et al., 2021\)](#page-12-3) for avian species and BatDetect2 [\(Mac Aodha et al., 2022\)](#page-13-0) for UK bat species, and evaluate their performance following a month deployment. Finally, we discuss the main limitations and highlight key considerations for the effective use of acoupi.

FIGURE 1 Overview of acoupi (A) Traditional PAM workflows consist of fragmented steps requiring frequent intervention, limiting scalability. These steps include device deployment, data retrieval and transfer to a central location, data management, data analysis to extract acoustic events, and finally, ecological inference. (B) acoupi integrates this workflow into a single device that supports on-board AI-based processing and wireless data transfer, reducing interventions and accelerating data turnaround. (C) acoupi adopts a plug-and-play approach, allowing users to configure workflows to their needs. Users can specify configuration parameters, select an AI-based model, and set up wireless network endpoints for integration with third-party applications. acoupi coordinates essential tasks (orange) like data collection and management, as well as optional modules (dotted) for data processing, transfer and reporting.

2 | **SOFTWARE OVERVIEW**

The acoupi software is structured in two main parts: a *framework* that provides tools for building programmes and an *application* that manages the configuration and execution of these programmes on edge devices. Central to acoupi is the concept of a *"programme"*, defined as a collection of tasks executed by the device. Each task represents an independent unit of work, for example data collection, processing, management, or transfer, which together define the behaviour of the bioacoustic sensor (Fig. [2\)](#page-4-0). The *framework* provides a flexible yet structured and standardised approach for defining programmes. The *application* ensures the harmonious and fault-tolerant execution of a programme. Moreover, it allows users to customise programmes parameters via a simple command-line interface (CLI), facilitating a "no-code" approach.

2.1 | **acoupi Framework**

The acoupi framework is designed to simplify the creation of customised programmes. While customisability is a primary objective, a key secondary goal is programme standardisation. This is achieved by enforcing that programme inputs, behaviours, and outputs are consistent across all programmes. This standardisation offers several advantages: it guarantees compatibility of user customisations within the framework, facilitates collaborations and sharing among users, and eases integration with other devices and third-party services. Standardisation also establishes a common language for understanding and discussing programme design. To achieve these objectives, the acoupi framework provides a suite of tools organised into four layers of increasing flexibility. This section introduces each layer, highlighting their role in programme creation and customisation.

F I G U R E 2 **Example of a simplified** acoupi **programme.** This programme (mauve) implements five tasks: (1) recording, (2) detection, (3) messaging, (4) summary, and (5) management. Each task (orange) follows a standardised workflow of individual components (dark purple), involving actions (rectangles) and decisions (rhombuses). Tasks can be scheduled to occur at regular time intervals (indicated by a clock), or triggered by other tasks (without a clock). Users can exchange components to modify device behaviour, customising how actions are performed and decisions are made without altering the overall workflow. Component behaviour can be fine-tuned through user-provided configuration parameters. Standardised data objects (light grey) flow between components, ensuring consistency across the workflow.

The **programme** layer provides *programme templates* that require minimal modification to create fully functional programmes. Each template consists of a set of operations that can be extended or adapted (Fig. [2\)](#page-4-0). For example, the *BasicProgram* template includes the minimum operations for a valid acoupi programme, corresponding to recording and saving of audio files. In contrast, the *DetectionProgram* template offers the full set of acoupi features, providing tasks to record audio, process recordings using an AI-based model, transfer results wirelessly to a remote server, manage the saving and deletion of audio files and metadata, and create periodic summaries of the system.

The **tasks** layer provides additional control to the pre-defined programme templates. In acoupi, a task can be any user-defined Python function, yet to facilitate standardisation and streamline development, the framework offers six *task templates* covering common operations. These include: (1) *recording* to collect audio data following a user-defined schedule, (2) *detection* to process captured recordings, (3) *messaging* to transmit detections to a remote server, (4) *summary* to generate periodic analytical reports, (5) *management* to organise data storage and handle audio files, and (6) *heartbeat* to monitor system health. Tasks can either be scheduled, for example, to record audio at regular intervals or triggered by other tasks, such as using a DL model to process a recording file as soon as a recording finishes. The

tasks built with these templates follow a standardised sequence of actions and decisions, which are implemented by the user-provided components (Fig. [2\)](#page-4-0).

The **components** are reusable and perform one specific operation based on the configuration input of an acoupi programme. All components adhere to a set of definitions, called component types, which specify the functionality of a component, its inputs, and outputs. For instance, the *Storage* component provides users with the ability to interact with a local database to store metadata of captured recordings, or to store the detections and classifications outputs after a recording has been processed. Furthermore, the *RecordingSavingFilter* component allows audio files to be saved based on criteria such as recording time, detection confidence score or specific classification tags.

The **data schema** layer defines a set of "data objects" made of specific data types (e.g., string, float, path). These data objects standardise data exchange between components. They are packets of information that are generated during the execution of a programme. Examples of data objects are Recording, Detection, and Message. These objects help to ensure consistency and compatibility throughout the programme flow.

A comprehensive overview of the programmes, tasks, components and data schemas, along with step-by-step instructions for modifying and creating new programmes, can be found in the documentation under the ["How-To](https://acoupi.github.io/acoupi/howtoguide/programs/) [Guides: Create a custom programme".](https://acoupi.github.io/acoupi/howtoguide/programs/)

2.2 | **acoupi Application**

The acoupi application enables the execution of a pre-built programme on a chosen edge device (Fig. [3\)](#page-5-0). The application provides a command-line interface (CLI) with simple commands to manage and deploy programmes. The command *"acoupi setup"* guides users through a configuration wizard, allowing them to select a programme and configure its parameters. The validity of the configurations can be checked and modified using the command *"acoupi config"*. Once a programme is configured, users can initiate deployment with the command *"acoupi deployment start"*. The application performs pre-deployment health checks to verify the programme configuration and system setup, identifying potential issues such as connectivity problems or microphone malfunctions. Finally, the command *"acoupi deployment stop"* shuts down the system and records the start and end times of a deployment.

F I G U R E 3 **Overview of the steps to install, configure, and start an** acoupi **application.**. Step (1) downloads and installs the acoupi software from the PyPi repository on a single-board computer. In step (2), users select and input the configuration parameters of an acoupi programme via a command-line interface. The configuration parameters define how the recording, processing, messaging, summary, and management tasks are executed. In step (3), users start a deployment running the configured acoupi programme.

The acoupi application ensures the timely execution of programme tasks. Maintaining reliable operation on edge devices can be difficult due to computational resource limitations, network instability, and power fluctuations. To address this, acoupi leverages Celery [\(Solem et al., 2025\)](#page-14-6), a robust and widely-used task management tool. Celery helps coordinate and schedule tasks, automatically retries failed tasks, and runs multiple tasks simultaneously whenever possible. Furthermore, acoupi incorporates mechanisms for automatic recovery after power failures. A comprehensive log of device activities is maintained aiding in identifying failures and preventing data loss.

To optimise storage usage during deployments, acoupi does not store recordings by default. Instead, recordings are temporarily held in the working memory for processing. Depending on the programme's logic and configuration, recordings may be selectively saved, such as when an AI-based model identifies vocalisations of target species. Both the chosen programme and its configurations are stored, facilitating the reproducibility of deployments by sharing configuration files. Additionally, acoupi stores lightweight SQLite databases containing essential recording metadata and automated detections. This design helps mitigate the risk of premature termination of the deployment due to storage depletion while maintaining crucial metadata for subsequent analysis and reproducibility.

2.3 | **Requirements**

To run acoupi, a single-board computer (SBC) running a Linux operating system (OS) is required. acoupi has been extensively tested on a Raspberry Pi 4 Model B running the 64-bit RPi OS; however, devices with similar specifications should be compatible. RPi boards are recommended for new users due to their beginner-friendliness and extensive documentation [\(Jolles, 2021\)](#page-12-7).

In addition to a SBC, a microphone and a microSD card are required. The microphone should be selected according to the desired sampling rate, which depends on the target species' vocalisation frequencies. To ensure adequate capture, the sampling rate should be greater than twice the highest frequency of the target vocalisation. A microSD card with a minimum capacity of 32GB is recommended. Users should select a larger capacity microSD card or consider an external hard drive, based on the volume of audio files they wish to archive for offline analysis post-deployment.

A detailed step-by-step installation is available at <acoupi.github.io/acoupi/#installation>.

3 | **PRE-BUILT PROGRAMMES**

We develop two ready-to-use programmes: *acoupi_birdnet* and *acoupi_batdetect2*. These programmes offer out-ofthe-box functionality that can be customised through configuration adjustments without requiring any coding. Both programmes are built upon the DetectionTemplate described in the previous section and thus inherit a common structure while incorporating distinct AI-based models and default configurations.

These programmes leverage two established DL models for the acoustic detection of birds and bats. *acoupi_birdnet* employs the BirdNET model version 2.4 [\(Kahl et al., 2021\)](#page-12-3), capable of detecting approximately 6,400 bird species globally, along with other relevant acoustic events such as frog calls, domestic animals, fireworks, and engine noise. *acoupi_batdetect2* utilises the BatDetect2 model [\(Mac Aodha et al., 2022\)](#page-13-0), designed to detect echolocation calls from 17 bat species commonly found in the UK. BirdNET and BatDetect2 models were trained using recordings made at 48kHz and 256kHz, respectively, thus using the same or similar sampling rate when using these models is recommended for better performance. These models showed good performance within the scope of their original evaluations [\(Pérez-Granados, 2023\)](#page-14-7). As with all DL models, there is the potential for misidentification or missed detections, particularly in environments dissimilar to their training data [\(van Merriënboer et al., 2024\)](#page-13-6). Thorough evaluation of model performance within the specific deployment context is strongly recommended [\(Wood et al., 2024\)](#page-15-6).

Both *acoupi_birdnet* and *acoupi_batdetect2* feature automated and scheduled recording, processing with their respective DL models, and transmission of detections to a remote server. *acoupi_birdnet* captures nine seconds every ten seconds between 03:00 and 23:00, while *acoupi_batdetect2* records three seconds of audio at the same frequency between 19:00 and 07:00. Detections exceeding a predefined confidence threshold are transmitted to a remote server every 30 seconds. A heartbeat signal is transmitted every 30 minutes to monitor device health, regardless of recording activity or detection events. The programmes allow for optional storage of recordings with confident detections, facilitating post-deployment validation. Crucially, all operational parameters, including recording schedules, durations, frequencies, and messaging intervals, are fully configurable. It is essential to carefully consider the monitoring goals and adjust these settings accordingly [\(Teixeira et al., 2024\)](#page-15-7).

4 | **SOFTWARE TESTING**

To test the reliability of acoupi, we configured and deployed both the *acoupi_birdnet* and *acoupi_batdetect2* programmes on two separate RPi 4B devices. The RPis were deployed in the People and Nature Garden Lab on the roof of UCL One Pool Street building within the Queen Elizabeth Olympic Park in London, UK (51° 32' 18.8" N, 0° 0' 32.36" W). This location was selected for initial software testing due to convenient access to power and Wi-Fi network, acknowledging that such conditions may not fully represent the challenges of field deployments. Most of the configuration parameters for the *acoupi* birdnet and *acoupi* batdetect2 programmes followed the default configuration (Appendix [A.2\)](#page-16-0). The devices were deployed for 30 days between October and November 2024.

TA B L E 1 **Deployment metrics of** *acoupi_birdnet* **and** *acoupi_batdetect2***.** Key metrics from a month deployment, including the total number of recordings, the count (and percentage) of unprocessed recordings, and the count (and percentage) of messages successfully sent to the remote server.

To evaluate the reliability of the software, we examined key metrics, including recording consistency, processing success, and message delivery (Table [1\)](#page-7-0). Both programmes successfully recorded at every scheduled interval; however, minor imprecisions in the scheduler resulted in an average recording frequency of approximately 10.005 seconds (Appendix [A.3\)](#page-18-0). Most of the recordings were successfully processed by the integrated DL models. The *acoupi_birdnet* processed all but four recordings, while the *acoupi_batdetect2* exhibited a slightly higher failure rate, with 1.83% of recordings not being processed. Both programmes reliably delivered all generated messages, indicating stable message delivery under good network conditions. Despite these positive results, both deployments encountered premature termination. The device running *acoupi_birdnet* was likely dislodged by strong winds, resulting in power loss. The *acoupi_batdetect2* programme encountered a software issue that accounted for the 1,203 unprocessed recordings. This issue has since been resolved. For a summary of the detections made by the two acoupi programmes, see Appendix [A.4.](#page-18-1)

5 | **LIMITATIONS AND FUTURE DIRECTIONS**

The present work showed how acoupi can be used to embed two bioacoustic DL models, BirdNET and BatDetect2. Although BirdNET covers a wide range of avian species [\(Kahl et al., 2021\)](#page-12-3), and BatDetect2 targets all bat species found in the UK [\(Mac Aodha et al., 2022\)](#page-13-0), it will be necessary to integrate additional AI-based models to accommodate a greater diversity of species and applications. Future updates could include any other AI-based models, such as the animal detection toolbox, Tadarida [\(Bas et al., 2017\)](#page-10-6) and the frog detector, RIBBIT [\(Lapp et al., 2021\)](#page-13-7). However, model integration requires considering their size and complexity, as these factors affect processing speed and power consumption on edge devices [\(Desislavov et al., 2023\)](#page-11-9). If processing times exceed the recording interval, processing backlogs and system overloads can occur. Optimisation techniques like quantisation [\(Krishnamoorthi, 2018;](#page-13-8) [Novac](#page-13-9) [et al., 2021\)](#page-13-9), pruning [\(Hoefler et al., 2021\)](#page-12-9), and knowledge distillation [\(Gou et al., 2021\)](#page-12-10) can reduce computational demands, but must be applied carefully to balance model compression and accuracy [\(Desislavov et al., 2023\)](#page-11-9). As models optimised for edge processing emerge [\(Disabato et al., 2021;](#page-11-7) [Zualkernan et al., 2021;](#page-15-3) [Höchst et al., 2022;](#page-12-8) [Ghani et al., 2023\)](#page-11-10), acoupi will provide a platform for their integration, making these advances accessible to the community.

In its month-long deployment at the People and Nature Lab in London, UK, acoupi successfully captured all scheduled recordings, sent all detection messages, and processed the majority of recordings using the embedded DL models. Nevertheless, the premature termination of both deployments underscores the need for more extensive field testing. While acoupi leverages established software tools to ensure reliable operation, empirical evaluations under varying network connectivity and power availability remain essential. Additionally, although acoupi is designed to operate on any Linux-compatible SBC, further testing on various SBCs would provide valuable insight into its compatibility and performance across different hardware platforms. Future acoupi development will focus on addressing these challenges through iterative improvements informed by field tests. The codebase includes automated tests to facilitate modifications as well as a system to distribute updates remotely, thus supporting the long-term maintenance and adaptability of the acoupi software.

In its first version, acoupi is limited to audio recordings as its primary data collection method and relies on Wi-Fi for communication. However, RPi-type boards support additional sensors and alternative connectivity such as cellular networks and LoRaWAN [\(Jolles, 2021\)](#page-12-7). One promising extension is the integration of multichannel audio recorders [\(Heath et al., 2024\)](#page-12-11), allowing on-board localisation algorithms to estimate the position of vocalising animals, a critical step for improving population density estimates [\(Rhinehart et al., 2020\)](#page-14-8). Furthermore, additional sensors to capture abiotic data, such as rainfall, wind speed, luminosity, temperature, and humidity, could provide an environmental context for ecological analyses, as these factors influence sound transmission and species detectability [\(Ross et al., 2021;](#page-14-9) [Metcalf et al., 2023\)](#page-13-10). Low-cost camera modules could also transform acoupi deployments into smart camera trap systems [\(Darras et al., 2024\)](#page-11-11) combining visual and acoustic monitoring. While these extensions await implementation, acoupi's modular framework provides the foundation for community-driven contribution and on-going development.

This work highlights the flexibility of acoupi, though its requirements may limit its use in certain monitoring scenarios. acoupi is designed for SBCs, which consume more power than MCUs, and requires a continuous power supply to ensure uninterrupted operation through solar panels with batteries or a connection to mains power. A complete deployment necessitates additional components, including a microphone and a protective enclosure, increasing overall cost and complexity. Whereas the base cost of an acoupi-compatible SBC is comparable to that of an AudioMoth, a full setup may exceed the budget of resource-constrained projects (see [Sethi et al. \(2018\)](#page-14-5) for the cost breakdown of an analogous system). Despite these limitations, acoupi is particularly well-suited for continuous and long-term monitoring of key sites with stable power and network access. Future iterations could incorporate power management mechanisms, like intelligent scheduling to optimise detection probability while minimising power use [\(Balle et al.,](#page-10-7) [2024;](#page-10-7) [Millar et al., 2024\)](#page-13-11).

The use of bioacoustic monitoring tools such as acoupi raises important ethical questions, particularly regarding privacy [\(Sandbrook et al., 2021\)](#page-14-10). PAM systems lack the ability to differentiate between wildlife vocalisations and human speech, leading to unintended capture of human conversations where consent is absent. Although researchers must adhere to responsible data handling practices like minimal data collection, secure storage, and timely deletion [\(Zook et al., 2017\)](#page-15-8), data upload to cloud-based storage and network devices remain vulnerable to security breaches and malicious attacks [\(Kim et al., 2022\)](#page-12-12). The on-device processing in acoupi offers a privacy advantage by allowing identification and immediate deletion of audio clips containing human voices [\(Cretois et al., 2022\)](#page-11-12). However, the initial release does not include human speech detection functionality and, therefore, users are strongly encouraged to ensure compliance with privacy regulations.

Ultimately, acoupi aims to provide a flexible, user-friendly tool for bioacoustic monitoring across diverse monitoring scenarios. For example, real-time detections generated by acoupi could be integrated into dashboards to create immediate alerts for time-sensitive events, such as mitigating human-wildlife conflicts, managing invasive species [\(Wood et al., 2024\)](#page-15-6), or dimming city lights in response to migratory bird movements [\(Horton et al., 2019\)](#page-12-13). Beyond real-time applications, these detections can support ecological research through methods like occupancy modelling [\(Rhinehart et al., 2022\)](#page-14-11) and call density analysis [\(Navine et al., 2024\)](#page-13-12). The validation of automated detections remains crucial when using AI models in novel environments [\(Pérez-Granados, 2023;](#page-14-7) [van Merriënboer et al., 2024\)](#page-13-6). acoupi can facilitate this validation by storing recordings that exceed a detection score threshold, or other criteria aligned with specific modelling requirements [\(Navine et al., 2024;](#page-13-12) [Knight et al., 2020\)](#page-13-13). By establishing standardised concepts, each with specified metadata, acoupi promotes integration and comparability of monitoring surveys, enabling ecologists to share findings, compare results between sites, and ensure reproducibility [\(Besson et al., 2022\)](#page-10-0).

As a final point, it is important to highlight the open-source nature of acoupi, which allows researchers to adapt and extend acoupi's customisable software modules to their specific requirements. We acknowledge that acoupi pre-configured programmes may not meet the needs of every researcher, and therefore invite and encourage the community to contribute to expand acoupi's functionalities. At its heart, acoupi aims to provide greater accessibility to bioacoustic monitoring, enabling real-time and automated monitoring for ecological research and conservation efforts.

Acknowledgements

This work was financially supported by URKI EPSRC (EP/R513143/1 and EP/T517793/1) and Consejo Nacional de Ciencia y Tecnologia (CONACYT) (2020-000017-02EXTF-00334). We thank Ella Browning for her feedback on the design of acoupi.

Conflicts of Interest

The authors declare no conflict of interest.

A.1 | **Examples Bioacoustic Research Projects**

TABLE 2 Quantity and size of audio recording for various acoustic research projects.

Project Description	Number of Recording Devices	Sample Rate (Hz)	Total Number of Recordings	Length of 1x Recording (minutes)	Total Recording Duration (hours)	Total Data Size (TB)
BiomeHealth, Maasai Mara, Kenya, 2019	74	384.000	87.543	1	1.459.05	32.27
Williams B. CoralReef, Pabbiring Islands Indonesia, 2022	18	16,000	267.688	1	4.461.46	0.514

TABLE 3 Transfer, speed and duration of audio data upload for various acoustic research projects.

A.2 | **Configuration Parameters of** acoupi **Deployment**

TABLE 4 Configuration parameters for acoupi_birdnet and acoupi_batdetect2 programmes.

Parameter	Values for acoupi birdnet	Values for acoupi_batdetect2	
Timezone	Europe/London	Europe/London	
Microphone			
Microphone Device Name	UAC 1.0 Microphone & HID-Mediak	UltraMic 250K 16 bit r4	
Microphone Samplerate	44100 Hz	250000 Hz	
Microphone Audio Channels	1	1	
Recording			
Duration	9 seconds	3 seconds	

Continued on next page

A.3 | **Results Summary of** acoupi **Deployment**

programme Name	Expected Nb. Recordings	Actual Nb. Recordings (Coverage %)	Nb. Recordings Processed	Nb. Recordings Unprocessed	Nb. Messages Sent Successfully	Nb. Messages Sent Failed
acoupi birdnet $130,098$		129.939 (99.88%)	129.935	4	8716	0
acoupi batdetect2	66.233	65.711 (99.21%)	64.508	1,203 (1.83%)	868	0

TA B L E 5 Summary of Deployment for *acoupi_birdnet* and *acoupi_batdetect2*.

TABLE 6 Summary of Detections for *acoupi* birdnet and *acoupi* batdetect2.

programme Name	Size of DB "metadata"	Size of DB "messages"	Total Nb. Detections	Nb. Detections (Detection Score > 0.4)	Nb. Predicted Tags (Classification Score > 0.4)	Nb. Different Species Class (Classification Score > 0.4)
acoupi birdnet 542.3 MB		10.4 MB	23.229	10.838	10.838	398
acoupi batdetect2	5.67 GB	1.0 _{MB}	19.416.908	1.031	174	$\overline{4}$

A.4 | **Summary of top 20 detection results for** *acoupi_birdnet* **and** *acoupi_batdetect2*

Although not the primary focus of this study, the detections made by the two bioacoustic classifiers were consistent with the expected soundscape of the deployment location and the seasonality of the test. The roof garden is urban, close to a busy traffic road, a railway track, but in the proximity of the Waterworks River, where common water birds are found.

Common UK bird species identified with high confidence (score > 0.85) included the Eurasian magpie (n=308), Eurasian wren (n=61), Redwing (n=50), European robin (n=38), White wagtail (n=31), Broad-winged hawk (n=25) and European herring gull (n=18). As expected, anthropogenic sounds were prevalent, with engine noise (n=73) and sirens (n=273) being the most frequently detected, followed by fireworks (n=175), likely associated with festivities during the deployment period.

The *acoupi_batdetect2* programme did not detect any bat echolocation calls with high confidence (score > 0.85), and the 174 pulses detected with moderate confidence (scores > 0.4) are likely false positives. This low number of bat detections is consistent with the deployment period (November), when most bat species in the UK are hibernating. Detections were not validated post-deployment. See tables [\(7](#page-19-0) and [8](#page-20-0) for a detailed summary of the detections made by the two bioacoustic classifiers.

Latin Name	Common Name	Max Confidence Score	Mean Confidence Score	Total Count	Confidence Score > 0.4	Confidence Score > 0.85	Comment
Engine	Engine	0.9897	0.4050	7955	3151	73	
Siren	Siren	0.9994	0.5684	1382	911	273	
Troglodytes troglodytes	Eurasian wren	0.9772	0.5056	1308	844	61
