# <span id="page-0-0"></span>Efficient Neural Theorem Proving via Fine-grained Proof Structure Analysis

Haoxiong Liu<sup>1†</sup> Jiacheng Sun<sup>2</sup> Zhenguo Li<sup>2</sup> Andrew C Yao<sup>13</sup>

## Abstract

The synergy between deep learning models and traditional automation tools plays a pivotal role in developing robust neural theorem provers (NTPs). However, for proof synthesis with LLMs, previous work applies automation tools either only when the model explicitly calls the method, or only at a single granularity level, failing to fully exploit the power of built-in tactics and off-the-shelf automated theorem provers. In this work, we propose *ProofAug*, a novel theorem proving method that enjoys superior sample efficiency through equipping proof-generation LLMs with automation methods in different granularities via fine-grained structure analysis of model-generated proof proposals. Furthermore, ProofAug serves as a versatile plug-and-play module that seamlessly integrates with any tree-search algorithm, enabling our construction of an efficient recursive proving (ERP) module to further enhance performance. The superiority of our method is validated on the miniF2F-test benchmark using the open-source deepseek-math-7bbase model and the Isabelle proof assistant. Notably, by additionally employing a mixed prompting strategy, we achieve a cumulative pass rate of 66.0% after curation of the dataset (61.9% for the original version), setting a new SOTA across all proof languages with a total sample budget of only 2100. Our code is available at [https://github.com/haoxiongliu/ProofAug.](https://github.com/haoxiongliu/ProofAug)

## <span id="page-0-1"></span>1. Introduction

Automated theorem proving is a field that not only appeals to mathematicians seeking efficient formalization and proof automation for mathematical theorems, but also finds significant applications in real-world industries such as integrated circuit design and software engineering [\(Bibel,](#page-8-0) [2013;](#page-8-0) [Schumann,](#page-8-1) [2013\)](#page-8-1). Early applications of machine learning methods on automated theorem proving focus on tasks such as premise selection [\(Irving et al.,](#page-8-2) [2016\)](#page-8-2) and proof search [\(Loos et al.,](#page-8-3) [2017\)](#page-8-3) in SMT solvers or resolution/ superposition provers, often interleaved with handcrafted heuristics. Recently, the rapid progress in mathematical reasoning with large language models (LLMs) has awoken a flourishing interest for directly synthesizing formal proofs using generative language models.

There are primarily two paradigms for direct proof synthesis: the proof-step generation paradigm and the whole-proof generation paradigm, each corresponding to a distinct proof style. For proof assistants where proofs are mainly in the procedural style (or tactic style), such as MetaMath [\(Megill](#page-8-4) [& Wheeler,](#page-8-4) [2019\)](#page-8-4) and HOL Light [\(Harrison,](#page-8-5) [2009\)](#page-8-5), previous work adopts the proof-step generation paradigm [\(Polu &](#page-8-6) [Sutskever,](#page-8-6) [2020;](#page-8-6) [Lample et al.,](#page-8-7) [2022;](#page-8-7) [Han et al.,](#page-8-8) [2022;](#page-8-8) [Polu](#page-8-9) [et al.,](#page-8-9) [2022\)](#page-8-9), where in each iteration the model is requested to generate one tactic to be applied in the interactive theorem prover (ITP). The ITP provides information about the updated proof state, which will be included in the prompt for the generation of next tactic. Proof-step generation methods typically use tree-search algorithms to guide the proving process, inspired by the success of AlphaGo [\(Silver](#page-8-10) [et al.,](#page-8-10) [2016\)](#page-8-10). In contrast, for proof systems that support declarative (or term-style) proofs such as Isabelle and Lean, computation-efficient whole-proof generation methods become possible. Nevertheless, the sample efficiency under this paradigm is not free. Any incorrect application of a proof method bridging the gap between two proof terms (or goals/conjectures) will cause the proof to fail to pass the verification check of the ITP.

To avoid this issue, the Draft, Sketch, and Prove (DSP) framework [\(Jiang et al.,](#page-8-11) [2023\)](#page-8-11) proposes to let the model first write a formal proof sketch [\(Wiedijk,](#page-9-0) [2004\)](#page-9-0) according to an informal proof draft, then offload the proofs of intermediate conjectures to off-the-shelf  $ATPs<sup>1</sup>$  and heuristic proof methods. Many subsequent works [\(Wang et al.,](#page-9-1) [2023a;](#page-9-1) [Zhao et al.,](#page-9-2) [2023;](#page-9-2) [Zheng et al.,](#page-9-3) [2024;](#page-9-3) [Zhao et al.,](#page-9-4) [2024\)](#page-9-4) also

Preprint. Under review.

<sup>&</sup>lt;sup>1</sup>For simplicity, we use the abbreviation ATP to refer to both SMT solvers and automated theorem provers rooted in the tradition of TPTP [\(Sutcliffe,](#page-8-12) [2009;](#page-8-12) [Blanchette et al.,](#page-8-13) [2013\)](#page-8-13). This is also the practice in [Jiang et al.](#page-8-11) [\(2023\)](#page-8-11).

follow the practice of DSP when designing their few-shot prompts: The proof methods in the original proofs of the demonstration examples are replaced with a placeholder, which signifies that ATPs are responsible for completing the task. We observe that while this approach can significantly enhance performance compared to direct full-proof generation, it may also result in proof failures in unintended ways:

- (Hard Conjectures) In DSP, the in-context learning ability of LLMs makes them follow the style of the few-shot prompt to generate rough sketches according to the informal proof, refusing to dive into the necessary details. As a result, the generated intermediate conjectures could be too hard for ATPs to solve.
- (Complicated Draft) Due to the mismatch between informal proof and formal system, there are conjectures that despite being easy to be solved by ATPs, humans need to write complicated informal proofs for them. The unnecessary intermediate steps could be translated into formal conjectures that are inappropriate in syntax or even harder than the original theorem.

Here, a dilemma appears. On one hand, instructing the model to produce a rough sketch increases the risk of missing critical details, making it challenging for ATPs to bridge the gaps. On the other hand, directing the model to generate highly detailed sketches can exacerbate formalization issues.[2](#page-0-0) Neither way is ideal for fully leveraging the power of off-the-shelf automation methods.

In this paper, we propose to address this dilemma through performing fine-grained structural analysis on the proof proposals generated by LLMs, based on the observation that regardless of correctness, full proofs contain rich struc-tural information from which valid semi-proofs<sup>[3](#page-0-0)</sup> of varying granularities can be derived. Specifically, given a theorem statement, instead of instructing the model to generate a proof sketch as previous work does, we choose to start from generating a full proof to suppress the 'Hard Conjectures' issue in the first place. For the generated proof proposal, we first find its corresponding *maximal compatible semiproof* (MCSP) that maintains most structural information yet can pass the check of ITP. Then, departing from it, we recursively resort to a more coarse semi-proof whenever ATPs fail to fill in some gap in the current one. This procedure solves the 'Complicated Draft' issue, thus significantly improving the sample efficiency. Figure [1](#page-2-0) shows an example flow of our method.

We also demonstrate that the application of proof structure

analysis is not restricted to single-pass generation. In fact, ProofAug can be incorporated into any tree-search algorithm to expand the candidate node set at each iteration. This will become evident in our unified view of theorem proving introduced in Section [2.1.](#page-1-0) In Section [3.3,](#page-5-0) we illustrate its application in enabling a sample-efficient approach to recursive theorem proving [\(Wang et al.,](#page-9-5) [2024\)](#page-9-5).

We list our contributions with corresponding key evaluation results using below. All experiments use the open-source deepseek-math-7b-base model [\(Shao et al.,](#page-8-14) [2024\)](#page-8-14).

- We propose a novel neural theorem proving method, ProofAug, based on fine-grained proof structure analysis. On miniF2F-test [\(Zheng et al.,](#page-9-6) [2021\)](#page-9-6), ProofAug achieves a pass rate of 52.5% with no more than 100 queries to the model. To the best of our knowledge, no previous work reports a higher pass rate with equal or fewer times of queries. Ablation results show that when compared with the DSP baseline, the improvement brought by ProofAug is 7.8%, 4.1% and 3.3% under sample budgets of 1, 10 and 100, respectively.
- ProofAug can be incorporated into any tree-search algorithms under our unified view of existing generative LM based theorem proving methods. We showcase that when integrated with our efficient recursive proving (ERP) module, 0-shot ProofAug performance improves from 54.5% to 56.1% with a limit of 500 queries per problem. As a comparison, RMaxTS [\(Xin](#page-9-7) [et al.,](#page-9-7) [2024b\)](#page-9-7) only shows < 0.2% advantage over naive single-pass retrying under a sample budget of 3200.
- Moreover, using a mixture of strategies with different promptings, we achieve a total pass rate of 61.9% within 1700 model queries. After curating the miniF2Ftest data, we manage to prove 66.0% of the theorems with no more than 2400 requests, setting a new state of the art across all proof languages on this benchmark.

## 2. Preliminaries

## <span id="page-1-0"></span>2.1. A unified view of theorem proving with generative language models

We first formulate the task of theorem proving in the context of language modeling and introduce our notations. We assume there is a global alphabet  $\Sigma$ . An ITP is formulated as a triple  $(A, S, T)$ , where:

- $A \subset \Sigma^*$  is the set of proof steps. There is also a parser Parse :  $\Sigma^* \to A^*$  that transforms a string into a sequence of proof steps.
- S is the set of *states*. A state  $s \in S$  represents our abstraction of the proof object underlying the ITP, which contains all information the ITP needs to proceed with the proof, including s.state, s.error, s.finish, etc.,

<sup>&</sup>lt;sup>2</sup>We refer the readers to Appendix [B](#page-10-0) for two concrete examples that illustrate these two issues.

<sup>&</sup>lt;sup>3</sup>By semi-proofs, we refer to proofs that possibly contain symbols indicating pending proof, such as sorry in Isabelle.

<span id="page-2-0"></span>

Figure 1: Illustration of our ProofAug method by an example. Each box in the flowchart corresponds to a proof step. (a) The initial proof encounters an error when proving Conjecture 1-0. (b) We replace the original proof of Conjecture 1-0 with a sorry and continue, until a syntactic error occurs at Conjecture 1-1. (c) The proof of Conjecture 1 is replaced by sorry and we obtain a semi-proof with two sorrys. (d) Automation tools are called to prove Conjecture 0 and Conjecture 1, but failing at the latter one. (e) The ERP module (introduced in Section [3.3\)](#page-5-0) sends a completion request at Conjecture 1. (f) The generated ERP proof still fails at Conjecture 1. (g) We finally resort to a more coarse level of proof and successfully find a proof with automation tools. Refer to Algorithm [2](#page-5-1) for a pseudo-code description of ProofAug.

varying depending on the specific ITP environment. Additionally, there is a special element  $s_0$ , which represents the initial state.

•  $T : \mathcal{S} \times \mathcal{A} \rightarrow \mathcal{S}$  is the state transition function of the ITP.

For any string  $x \in \Sigma^*$ , we use  $s_x$  to denote  $T(s_0, x)$ , where we have lifted the notation  $T$  to express consecutive state transitions, i.e., for  $s \in \mathcal{S}$ ,  $T(s, x) = T(\cdot, \mathbf{a}[n]) \circ T(\cdot, \mathbf{a}[n] 1]$ )  $\circ \cdots \circ T(\cdot, \mathbf{a}[1])(s)$  if  $\text{Parse}(x) = (\mathbf{a}[1], \mathbf{a}[2], \cdots, \mathbf{a}[n]).$ 

Given a theorem statement (with context)  $x_f \in \Sigma^*$ , we say  $y_f \in \Sigma^*$  is a *proof* of  $x_f$  if  $s_{x_f \| y_f}$  finish = True, where  $\parallel$ denotes the concatenation of two strings. A generative language model (with a decoding strategy) is a map that outputs a distribution  $\pi(\cdot|x)$  on  $\Sigma^*$  when conditioned on a *prompt*  $x \in \Sigma^*$ . A *response* is a sample  $y \sim \pi(\cdot|x)$ . The task of theorem proving is to find a proof  $y_f$  of the given theorem statement  $x_f$  using the black-box distribution generator  $\pi$ . Some benchmarks also provide a corresponding informal statement  $x_i$  and informal proof  $y_i$  for each theorem.

We state our unified view of existing generative-LM-based theorem proving methods as follows. In each round, an algorithm completes three steps:

1. (*State Selection*) Select a state to work with in this round.

- 2. (*Prompt Formation*) Form a prompt and present it to the model.
- 3. (*Response Processing*) Use the response of the model to interact with ITP to generate new states.

Compared to typical views of tree-search algorithms, our approach integrates their expansion step and back-propagation step with the process of interacting with the ITP into a single response processing module. We isolate the prompt formation procedure into a single module to emphasize its importance, as proof-step generation methods and wholeproof generation methods differ fundamentally at this point. Besides, this allows us to place not only these two lines of work, but also methods that lie in between, under our unified view.

Table [1](#page-3-0) summarizes and compares different methods under this view. Our view disentangles the different modules of algorithm design, naturally motivating us to optimize existing algorithms in the module-level. Our method *ProofAug*, which will be introduced in Section [3.2,](#page-4-0) is a procedure belonging to the response processing step. Thus, we can integrate effective practices in other modules with ProofAug to make further improvements. We showcase such an application in Section [3.3.](#page-5-0) Moreover, since the goal of theorem proving is to improve the overall pass rate rather than the success rate of each attempt, an appropriate 'portfolio'

<span id="page-3-0"></span>Table 1: A summary of current theorem proving methods using generative language modeling under our unified view, including DSP [\(Jiang et al.,](#page-8-11) [2023\)](#page-8-11), LEGO-Prover [\(Wang et al.,](#page-9-1) [2023a\)](#page-9-1), Lyra [\(Zheng et al.,](#page-9-3) [2024\)](#page-9-3), GPT-f [\(Polu & Sutskever,](#page-8-6) [2020\)](#page-8-6), HTPS [\(Lample et al.,](#page-8-7) [2022\)](#page-8-7), ReProver [\(Yang et al.,](#page-9-8) [2023\)](#page-9-8), Lean-STaR [\(Lin et al.,](#page-8-15) [2024\)](#page-8-15), POETRY [\(Wang et al.,](#page-9-5) [2024\)](#page-9-5), RMaxTS [\(Xin et al.,](#page-9-7) [2024b\)](#page-9-7). We use the terms *node* and *state* interchangeably.

of different strategies for each module could significantly improve the pass rate than a single strategy. Such a phenomenon has been observed in the CoT & non-CoT mode combination [\(Xin et al.,](#page-9-7) [2024b;](#page-9-7) [Zhao et al.,](#page-9-4) [2024\)](#page-9-4). In Section [4.3,](#page-6-0) we explore this idea across additional combinations and demonstrate its superiority.

#### 2.2. Isabelle/Isar Proof Language

Although the basic idea of our method in general fits in any  $ITP<sup>4</sup>$  $ITP<sup>4</sup>$  $ITP<sup>4</sup>$ , the implementation details vary depending on specific

features of the proof assistant. In this section we introduce some basic knowledge and unique features that ease the implementation of our method in Isabelle/Isar [\(Wenzel et al.,](#page-9-9) [2004\)](#page-9-9), the proof language used in this work.

The specific object corresponding to our 'state' abstraction formulated in Section [2.1](#page-1-0) is Isar/VM transition. The transitions are typed with different modes, including proof(prove), proof(state) and proof(chain). We find that identifying the mode proof(prove) is particularly useful for the analysis of proof structure since it indicates that a goal has just been declared and the next proof step is required to contain a proof method. In Isar, proof methods are only allowed to be invoked after the keywords proof and qed. As a result, a typical proof in Isar is organized by hierarchical proof...qed blocks.

Figure [2](#page-3-1) shows an example of Isar proof. Users are allowed to have or show are keywords that Isabelle allows to appear in the proof(state) mode to introduce new local goals. To prove a goal with some proof method m, one can use a single clause 'by  $m'$ , which is an abbreviation of 'proof m qed'. The other keywords, assume and with, serve exactly the same purpose as they do when used in natural language proofs. Benefiting from the above properties, Isar proofs are readable even for people unfamiliar with Isabelle, thus easy to be analyzed just like how we analyze the structure of an informal proof.

Finally, we specify the attributes we can access from a state s through the ITP environment used in this work. We can have a proof state string s.state that corresponds to the

<sup>&</sup>lt;sup>4</sup> See Appendix [C](#page-10-1) for a detailed explanation of why our method is generic across different systems.

<span id="page-4-1"></span>

'proof state' Isabelle shows to the user, a corresponding mode s.mode, a list of all available facts s.facts that can be obtained by the print facts command in Isabelle, and two boolean-type attributes s.error and s.finish indicating whether 'an error has occurred' and whether 'a theorem is proved', respectively. We say  $s_1 = s_2$  for two states  $s_1, s_2 \in S$  if all the values of these five attributes are equal.

## 3. Method

Algorithm [2](#page-5-1) describes our method, ProofAug. It mainly consists of three parts: finding the Maximal Compatible Semi-Proof (MCSP), proof augmentation, and an optional Efficient Recursive Proving (ERP) module. In this section, we state each of them in details. For an illustrative walkthrough example of ProofAug, refer to Figure [1.](#page-2-0)

#### 3.1. Find the Maximal Compatible Semi-Proof

Given a proof proposal  $y_f^0$  sampled from  $\pi(\cdot | p(x_i || y_i, x_f))$ (where  $p(\cdot, \cdot)$  is a few-shot/zero-shot prompter that appropriately combines its arguments), the first procedure of ProofAug is to find the *Maximal Compatible Semi-Proof* (MCSP) of  $y_f^0$ .

We first explain what the MCSP is. Recall that a *semi-proof* refers to a *proof* that possibly contains sorry steps. We say a semi-proof y is *compatible* to  $y_f^0$  if each **sorry** in y matches a **proof...qed** block or a **by** clause in  $y_f^0$  and the remaining parts are equal. Thus, by MCSP, we refer to the particular compatible semi-proof  $y_f^M$  from which all compatible semiproofs (w.r.t.  $y_f^0$ ) can be obtained by substituting some **proof...qed** blocks or **by** clauses of  $y_f^M$  with **sorry**s.

The FindMCSP routine is described in Algorithm [1.](#page-4-1) Firstly,  $y_f^0$  is parsed into a sequence of proof steps a. Then we create a pointer  $i$  indicating the current position and an array s indicating the states before the ith step. In each iteration, we first try to proceed with current proof step  $a[i]$  from the current state  $s[i]$  in the ITP. If this step succeeds, we continue to the next proof step; otherwise, according to the proof mode of  $s[i]$ , we take different strategies: if  $s[i]$ .mode is **proof(prove)**, we replace  $a[i]$  with sorry; otherwise, we find the innermost **proof...qed** block of  $y_f^0$  that contains the  $i$ -th step and substitute the whole block with a single sorry step, then move the pointer accordingly. The algorithm terminates when a failed step occurs outmost or all steps pass the check of ITP.

#### <span id="page-4-0"></span>3.2. Proof Augmentation

The goal of ProofAug is to determine whether there exists a compatible semi-proof that can be completed into a valid proof using ATPs or built-in heuristic proof methods to fill the sorry gaps. Instead of first finding out all compatible semi-proofs and trying them one-by-one, we should design a more efficient way that makes use of the overlap among these semi-proofs to avoid waste of computation resources spent on calling ATPs. The resulted proof augmentation algorithm is shown in Algorithm [2](#page-5-1) (Ignore the ERP module for now).

Specifically, we first parse the MCSP and create a pointer and a corresponding state array as in Algorithm [1.](#page-4-1) When we encounter a sorry step as we progress with the proof, we try a predefined set of Isabelle built-in heuristic methods and Sledgehammer to find a proof of the current goal. This procedure can be seen as a special proof method <ATP> created by us, similar to the built-in proof method try. If this <ATP> method fails, we can rule out the possibility that the final proof contains the innermost proof...qed block in which this sorry lives and replace the block with sorry. We iteratively perform this operation until we finish the proof, or the semi-proof degrades into a single sorry step and <ATP> fails to directly prove the original theorem.

For a concrete example of ProofAug inducing a proof from a failed initial proof proposal, refer to Appendix [H.](#page-14-0)

<span id="page-5-1"></span>Algorithm 2 Proof Augmentation (ProofAug)

**Input:** theorem statement  $x_f$ , informal statement  $\&$  draft  $x_i||y_i$ , prompter  $p(\cdot, \cdot)$ , LM  $\pi(\cdot|\cdot)$ , ITP  $(\mathcal{A}, \mathcal{S}, T)$  $y_f^0 \sim \pi(\cdot|p(x_i\|y_i))$  $\triangleright$  Sample an initial proof  $\mathbf{a} \leftarrow \text{Parse}(\text{FindMCSP}(y^0_f))$  $\triangleright$  Apply Algorithm [1](#page-4-1)  $\mathbf{s} \leftarrow [Null] \times len(\mathbf{a})$  $i, s_{this} \leftarrow 1, s_0$ while  $i \leq len(a)$  do  $s_{next} \leftarrow T(s_{this}, \mathbf{a}[i])$ if  $a[i] \neq$  sorry then  $error \leftarrow False$ else  $error \leftarrow T(s_{this}, \langle \text{ATP} \rangle) . error \qquad \triangleright \text{Try ATPs}$ end if if error and use $ERP$  then  $\triangleright$  ERP module  $y_f^p \leftarrow \mathbf{a}[1..i-1] \|s_{this}.state$  $y_f^c \sim \pi(\cdot | p(x_i \| y_i, x_f \| y_f^p))$ if  $T(s_{this}, y_f^c) = s_{next}$  then  $[{\color{red} a}[i], error \gets y^c_f, False]$ else  $y_f^a \leftarrow$  FailedTactics2ATP $(y_f^c)$ if  $T(s_{this}, y_f^a) = s_{next}$  then  $a[i], error \leftarrow y_f^a, False$ end if end if end if if  $error$  then  $\triangleright$  Resort to the last level  $block \leftarrow$  InnermostBlock $(i, a)$ if *block* is Null then return Null  $a[block.start..(block.end - 1)] \leftarrow Null$  $a[block.end] \leftarrow$  sorry  $i, s_{this} \leftarrow block.end, \mathbf{s}[block.start]$ else  $i, s_{this} \leftarrow i + 1, s_{next}$ end if end while **return** Concat(a)  $\triangleright$  The final proof

#### <span id="page-5-0"></span>3.3. Efficient Recursive Proving

Solving a complicated theorem from a single proof proposal generated by the language model  $\pi(\cdot|\cdot)$  is challenging even with our ProofAug procedure. By simply sampling more proof proposals, we can probably get better results as long as there is some randomness underlying the decoding strategy of  $\pi$ . We ask the question: how can we outperform this naive retrying strategy, given a fixed sample budget?

On miniF2F, [Wang et al.](#page-9-1) [\(2023a\)](#page-9-1); [Zheng et al.](#page-9-3) [\(2024\)](#page-9-3) achieve better performance than the naive approach by making use of the previous error messages or proved lemmas in the previous attempts of proofs. Nevertheless, these methods all belong to the whole-proof generation paradigm and

benefit from the strong instruction-following ability of GPTseries models. Here, we are more interested in going beyond whole-proof generation to investigate whether tree-search methods used in the proof-step generation paradigm can help improve the sample efficiency.

To the best of the authors' knowledge, RMaxTS[\(Xin et al.,](#page-9-7) [2024b\)](#page-9-7) is the only successful attempt to integrate some treesearch algorithm with whole-proof generation. However, the advantage of RMaxTS only becomes clear when the sample budget comes to  $4 \times 6400$ . Our explanation for this inefficiency is that, for proofs that deviate from the correct paths at a very early stage, RMaxTS could spend much time in searching after the proof steps that have already misled the direction of proof. We argue that this can be largely avoided if we can first check whether the proof proposal forms a valid reasoning path. POETRY[\(Wang et al.,](#page-9-5) [2024\)](#page-9-5) is a top-down approach that satisfies this property through fine-tuning the model to never step into the next proof level. However, POETRY falls in the proof-step generation paradigm and requires fine-tuning the model to follow their special proof-step generation strategy.

In order to achieve a more sample efficient and fine-tuning free recursive proving method, we design our algorithm in a modularize way under the unified view described in Section [2.1.](#page-1-0) Firstly, for the prompt design module that determines the expected output content, we borrow the proof completion module of RMaxTS to replace the proof-generation step of POETRY; then, for the response processing module, we perform proof structure analysis as in the proof augmentation procedure and try <ATP> for the failed proof...qed blocks or by clauses. A new node is added if the <ATP> method fails to solve the corresponding conjecture. For the state selection strategy, we follow the best-first strategy, but the priority is modified from the cumulative log-probability to the end position of the failed proof block, i.e., if one node is an ancestor of another, we prioritize the descendant; otherwise, we prioritize the one that appears first in the semi-proof.

In practice, to simplify the algorithm and suppress the sampling cost wasted in low-level details, we add new nodes and try  $\langle \text{ATP} \rangle$  for failed **proof...qed** blocks in the first iteration only. Such simplifications makes the above procedure become a plug-and-play ERP module over our ProofAug, as shown in Algorithm [2.](#page-5-1) This coincidence can be interpreted by that each conjecture naturally inherits one proof try from the original proof proposal. In other words, the ProofAug without ERP module is already implicitly a recursive proving method, in the sense that each compatible semi-proof exactly corresponds to one proof tree during the search process of POETRY if the the two methods share the same final proof.

For an illustrative example of how the ERP module works

in ProofAug, refer to Figure [1.](#page-2-0)

### 4. Experiments

A summary of our experimental results and comparison with previous methods is shown in Table [2.](#page-7-0) Below, we state the experimental setup and describe how different parts of the results are obtained and provide additional ablation study results.

#### 4.1. Experimental Setup

We evaluate our methods on miniF2F [\(Zheng et al.,](#page-9-6) [2021\)](#page-9-6), a benchmark for formal Olympiad-level mathematics problems in four different formal languages. Specifically, we use the Isabelle/Isar part of the miniF2F-test dataset provided by [Jiang et al.](#page-8-11) [\(2023\)](#page-8-11), which provides an additional informal statement and informal draft for each problem. We use the PISA environment [\(Jiang et al.,](#page-8-16) [2021\)](#page-8-16) to interact with Isabelle 2022. Our <ATP> method is the combination of 8 Isabelle proof methods (*auto, simp, auto, blast, fastforce, eval, sos, arith, simp:field simps, simp add:mod simps*) and Sledgehammer. Following [Jiang et al.](#page-8-11) [\(2023\)](#page-8-11), we set the timeout for any proof step and Sledgehammer as 10s and 120s, respectively. During verification, we run 12 PISA instances in parallel on one In-tel(R) Xeon(R) Gold 6326 CPU @ 2.90GHz<sup>[5](#page-0-0)</sup>.

The language model we use across all our experiments is deepseek-math-7b-base [\(Shao et al.,](#page-8-14) [2024\)](#page-8-14), run on Nvidia GeForce RTX 3090 with vLLM [\(Kwon et al.,](#page-8-17) [2023\)](#page-8-17). Unless otherwise specified, we follow [Jiang et al.](#page-8-11) [\(2023\)](#page-8-11) to use a sampling temperature  $T = 0.6$  with top  $p = 0.95$ . The default max number of tokens of the response is set to 2048, and when the length of the prompt exceeds 2048, we adjust the max number of tokens to 4096 − #token\_of\_the\_prompt.

For few-shot prompting (and similarly for zero-shot prompting), we prepare few-shot examples that are the same with those of [Jiang et al.](#page-8-11) [\(2023\)](#page-8-11) except that the proof sketches are modified to new full proofs written by us. For  $n$ -shots prompting, we randomly sample  $n$  examples from the candidates. By default, we use 1-shot prompting. See Appendix [E](#page-12-0) for our specific prompt text, the reason of choosing 1-shot, and more details on the prompt construction process.

For multiple attempts of proof, we record the checked semiproofs and skip them when obtaining them in the subsequent attempts. This will in fact harm the final performance since some tactics and Sledgehammer do not always give the same result under the same condition. Nevertheless, this practice can help us significantly reduce the elapsed time of

<span id="page-6-1"></span>

Figure 3: Ablation of three different prompting ways.

the experiments.

#### 4.2. Results of ProofAug

We do ablation study to validate the effectiveness of ProofAug (without the ERP module). We first get the DSP baseline results in our setting. Compared to the performance of the original DSP implementation on miniF2Ftest, our DSP baseline is 9.9% higher (49.2% v.s 39.3% in 100 attempts) due to differences on proving environments<sup>[6](#page-0-0)</sup>, choice of prompting method and model difference. Then we compare ProofAug results with our DSP baselines. Under sample budgets of 1, 10 and 100, ProofAug achieves performance of 36.5%, 44.7% and 52.5%, significantly outperforming the baseline by 7.8%, 4.1% and 3.3%, respectively.

Note that ProofAug can also be applied to the proof sketches generated by DSP. Figure [3](#page-6-1) shows how the number of proved theorems changes as the number of attempts increase w/ or w/o ProofAug for three prompting methods: DSP prompting, full proof prompting, and the more token-usage friendly zero-shot prompting. By w/o ProofAug, we mean the 'Prove' step in DSP, i.e., <ATP> is tried at the sorrys in the proof sketch. It can be seen that while the performance of our few-shot prompting and zero-shot prompting w/o ProofAug is much lower than that of DSP prompting, ProofAug helps them achieve a comeback. This justifies our choice of generating full proofs instead of proof sketches.

## <span id="page-6-0"></span>4.3. Results of the ERP module

We try 500 attempts of proof for each problem, using zeroshot prompting for ProofAug w/ and w/o ERP module. When then ERP module is turned on, we record the cumulative number of queries and stop verifying when it reaches 500 for a fair comparison.

 $5T_0$  reproduce our results, using the same CPU is a necessary requirement. See Appendix [D](#page-11-0) for more discussion on the reproducibility issues.

<sup>&</sup>lt;sup>6</sup>See Appendix [D](#page-11-0) for a discussion on the differences of theorem proving environment between ours and that of [Jiang et al.](#page-8-11) [\(2023\)](#page-8-11).

<span id="page-7-0"></span>Table 2: **Comparison of methods using Isabelle as the proof assistant on MiniF2F-test.** For BFS methods, the sample budget  $N \times S \times T$  corresponds to N attempts of S expansion with T iterations. As to tree-search methods, it becomes  $N \times T$ , with the same meanings for the symbols. Results with a  $\cdot^{\dagger}$  are obtained using a mixed strategy.

The result shows that ERP module can bring an extra 1.6% performance gain. If we do not restrict the number of queries, we can achieve a pass rate of 57.4%(+2.9% compared to the ProofAug without ERP).

#### 4.4. Cumulative Results of Mixed Strategy Experiments

During the completion of this work, we have tried various setups to search for the best recipe. While some setups fail to achieve the best performance on the benchmark compared to results we present above, diverse ways of generating proofs help prove more theorems. The setups include: 1) *Three versions of demonstration examples.* for few-shot prompting generation and two versions of zero-shot prompt are used in our experiments. 2) *Whether to include Informal drafts.* The informal drafts could mislead LLMs. Although ProofAug can sometimes be a rescue, it is not always the case. Besides, we find some incorrect theorem statements in the miniF2F-test dataset during our experiments, so we build a curated dataset and part of the experiments are done on the curated version.

In total, we try each problem of the original miniF2F-test under a sample budget of around 1400 in total, and 2100 for the two versions in total. See Table [3](#page-14-1) in Appendix [F](#page-12-1) for a breakdown of these two numbers. On the original miniF2F- test, we solve 61.9% of the problems, which is 5.8% higher than the previous Isabelle SOTA. On the curated version, the solving rate comes to 66.0%, setting a new state of the art across all proof systems.

### 5. Discussion and Future Directions

Although this work demonstrates that our ProofAug method significantly improves the performance of the neural theorem prover on the miniF2F benchmark, there remains a notable gap in tackling IMO-level problems or researchlevel challenges within formal systems. How to incorporate ProofAug into the expert iteration methods [\(Xin et al.,](#page-9-11) [2024a\)](#page-9-11) or online learning methods [\(Lample et al.,](#page-8-7) [2022\)](#page-8-7) to further improve the performance is one direction of the future work.

We believe that another important direction for future work is to fully leverage the robustness introduced by ProofAug through its ability to operate across various granularities and the fallback mechanism. Robustness is a highly desirable property for systems lacking inherent verification mechanisms, such as informal mathematical problem-solving and software engineering. Therefore, we are also highly interested in exploring the effective application of ProofAug in these domains.

### Impact Statement

This paper presents work whose goal is to advance the field of Machine Learning. There are many potential societal consequences of our work, none which we feel must be specifically highlighted here.

## A. Other Related Work

In the main body, Table [1](#page-3-0) and Table [2](#page-7-0) only include representative neural theorem proving methods that are most related to this work: they all target on solving Olympic-level mathematical problems with generative language models. Below we introduce other related work.

Premise Selection. One line of work uses embedding models to facilitate the selection of premises for automation tools [\(Irving et al.,](#page-8-2) [2016;](#page-8-2) [Wang et al.,](#page-9-12) [2017;](#page-9-12) [Goertzel et al.,](#page-8-18) [2022;](#page-8-18) [Yang et al.,](#page-9-8) [2023\)](#page-9-8). The machine-learning enhanced automation tools can be used to strengthen the power of the <ATP> method in our ProofAug algorithm. For example, the Magnushammer[\(Mikuła et al.,](#page-8-19) [2024\)](#page-8-19) is an ideal substitution for the sledgehammer, whose solving rate on miniF2F is 34.0% (against 20.9% of sledgehammer) and has a mode that does not require GPU or TPU accelerators. We believe that access to such tools can help ProofAug achieve better performance on theorem proving.

Hierarchical Theorem Proving. We note that the idea of hierarchically proving theorems in declarative ITP systems has been explored in several previous works. Besides the proof-step based recursive proving method POETRY [\(Wang et al.,](#page-9-5) [2024\)](#page-9-5) discussed in Section [3.3,](#page-5-0) LEGO-Prover [\(Wang et al.,](#page-9-1) [2023a\)](#page-9-1) uses a skill library to record the previously proved lemmas and retrieves relative skills when instructing GPT series models to synthesize its proof based on a decomposed informal draft. It is a hierarchical proving method in the sense that the lemmas used for proving current theorem can be built on more low-level lemmas. From another point of view, LEGO-Prover uses all previous queries to solve the current theorem hierarchically. In contrast, [Dong et al.](#page-8-20) [\(2024\)](#page-8-20) does not record a skill library, but finishes the hierarchical proving from scratch. The key difference between these hierarchical proving methods and our ProofAug (without ERP module) is that we work in a bottom-up fashion to best exploit the power of traditional automation tools, contrary to their top-down frameworks that all require extra queries to the model when stepping into the next level proof. We argue that bottom-up fashion aligns more with the pre-trained corpus, thus making best use of the theorem proving knowledge possessed by the model. In contrast, top-down methods require in-context learning or fine-tuning to control the behavior of LMs, which could hurt the intrinsic ability of the model and bring extra complexity to the problem. This is likely the underlying reason why ProD-RL [\(Dong et al.,](#page-8-20) [2024\)](#page-8-20) fails to make significant improvements over the simple SFT method on miniF2F-test. Whereas our ProofAug serves as a play-and-plug module and can fall back to naive single-pass generation, being superior in efficiency, robustness and flexibility. Moreover, by adding the ERP module, we integrate the top-down and bottom-up fashions in a sample-efficient way.

Declarative versus Procedural. The discussion of proof styles dates back to [Harrison](#page-8-21) [\(1996\)](#page-8-21). [Wiedijk](#page-9-13) [\(2006\)](#page-9-13) compares the proof styles of a wide range of different systems. [Wiedijk](#page-9-14) [\(2012\)](#page-9-14) discusses how to convert from procedural system to a declarative one. [Avigad et al.](#page-8-22) [\(2021\)](#page-8-22) introduces the two styles of proof in Lean and provides concrete examples.

Other proof-step generation works. Aside from works introduced in Table [1,](#page-3-0) such as [Polu & Sutskever](#page-8-6) [\(2020\)](#page-8-6); [Lample](#page-8-7) [et al.](#page-8-7) [\(2022\)](#page-8-7), [Han et al.](#page-8-8) [\(2022\)](#page-8-8); [Polu et al.](#page-8-9) [\(2022\)](#page-8-9); [Wang et al.](#page-9-15) [\(2023b\)](#page-9-15) are also valuable explorations on what practice is beneficial for tree-search proof-step generation methods. [Thakur et al.](#page-9-16) [\(2024\)](#page-9-16) designs an agent that makes use of the history ITP feedbacks in a serialization way.

Other whole-proof generation works. [Xin et al.](#page-9-11) [\(2024a\)](#page-9-11); [Wu et al.](#page-9-17) [\(2022\)](#page-9-17) verify the effectiveness of expert iteration on neural theorem proving using the naive whole-proof generation method. They build the first-round theorem statements through autoformalization of the informal problems. [First et al.](#page-8-23) [\(2023\)](#page-8-23) employs Isabelle error message to enhance the direct full proof synthesis ability of LLM.

## <span id="page-10-1"></span>C. Discussion of Implementing ProofAug for Other Proof Assistants

Lean. Although Lean proofs can be completely tactic-based, block-structures starting with *by* are very common as well, especially for the proofs of Olympics-level math problems (refer to [Xin et al.](#page-9-7) [\(2024b\)](#page-9-7) for the example proofs they find). As a result, Lean proofs are also amendable for proof structure analysis with some modifications. As to the substitution of the <ATP> method, firstly, there are built-in tactics such as simp, ring, nlinarith similar to the heuristics proof methods in Isabelle that have a predefined set of rules (facts) to use. Besides, there have been projects that can provide Lean

Figure 4: An example of the 'Hard Conjectures' issue. In this example, although the informal draft is reasonable to human, sledgehammer fails to find a proof for the final step.

```
theorem
  "gcd 180 168 = (12::nat)"by eval
theorem
  "gcd 180 168 = (12::nat)"proof -
(* If a number divides into both 180 and 168 *)
 have "gcd 180 168 dvd 180" sledgehammer
 moreover have "gcd 180 168 dvd 168" sledgehammer
(* it must also divide into their difference. *)
  finally have "gcd 180 168 dvd 12" sledgehammer
qed
Isabelle Info: Sledgehammering... No proof found
```
Figure 5: An example of the 'Complicated Draft' issue. In this example, while the eval proof method can prove the theorem easily in Isabelle, the translation of informal draft into a formal proof fails to pass the verification due to the lack of explicit type annotations, which is a typical error the language models could make in autoformalization.

tactics that discharge goals into SMT solvers already<sup>[7](#page-0-0)</sup>. It is hopeful that a Lean version of ProofAug can be constructed with the help of such tools by extra engineering efforts.

For procedural ITPs that work mostly in a tactic-based way and do not have block structures in the proofs explicitly, in principle, one can follow [Wiedijk](#page-9-14) [\(2012\)](#page-9-14) to build a proof interface that supports declarative style proofs upon the original system. Since [Wiedijk](#page-9-14) [\(2012\)](#page-9-14) also provides a generic way to convert the proofs in the original procedural language to declarative ones, one may obtain data for training language models on this new language by conversion of the corpora in the original language. Then one can perform ProofAug on this new declarative language.

## <span id="page-11-0"></span>D. Theorem Proving Environment Setup Details and Discussion on the Reproducibility

Our theorem proving environment setup mainly follows that described in [Jiang et al.](#page-8-11) [\(2023\)](#page-8-11), but there are some subtle differences. For the setup of PISA, we set the candidate provers of Sledgehammer to CVC4 vampire verit e spass z3 zipperposition, with a 30s timeout for each and 120s in total, as in [Jiang et al.](#page-8-11) [\(2023\)](#page-8-11). However, we find that in their PISA source code, they use cvc5 instead of CVC4 and the actual total timeout for Sledgehammer is around 35s instead of the intended 120s, seemingly due to an implementation bug. We fix this bug and still use CVC4 since cvc5

```
7
lean-smt
```
is not integrated in Isabelle 2022. We do not compile the Archive of Formal (AoF) library due to lack of disk space to simultaneously run 12 instances possessing compiled AoF heaps on our server. As a result, we do not import the Symmetric Polynomials.Vieta theory as in [Jiang et al.](#page-8-11) [\(2023\)](#page-8-11). Besides, The heuristics used in our <ATP> method and those in [Jiang et al.](#page-8-11) [\(2023\)](#page-8-11) differ in that we add an extra simp: add mod\_simps, remove force since we already have fast force and remove presburger, linarith since arith integrates the two in a rough sense.

To reproduce the results that involve the use of complex built-in proof methods or off-the-shelf ATPs, one has to make sure to run PISA instances on the same CPU since the performance of these automation methods heavily rely on the computational power of the CPU.

Nevertheless, even using the same environment, it is still hard to produce exactly the same results due to the inherent randomness of these automation methods. The good news, however, is that for theorem proving, we are confident that we have made some progress when new theorems get proved, no matter whether this is completely reproducible or not. So we focus on making sure the obtained proofs are correct by verifying them again in Isabelle. We provide the found proofs in attachment to our code. Note that although there are cases where the proofs might fail due to timeout of the reconstructed smt or metis proofs, it does not mean that the theorems are not proved. It is just the limitation of Isabelle's built-in tactics.

## <span id="page-12-0"></span>E. Prompt Construction

<span id="page-12-2"></span>{

}

The prompts in our experiments are all constructed from three components: prompt template, few-shot demonstration examples. and a prompter. The prompt template is a JSON file that contains different roles as names and corresponding templates as values. Each example is also an JSON object whose names occur in the templates. A prompter mainly consists of a chat template that maps the sampled examples to a conversation consisted by **messages** according to the prompt template.

For example, for few-shot prompting for ProofAug, we use the prompt template shown in Figure [6.](#page-12-2) The examples contain names  $x_i$ ,  $y_i$ ,  $x_f$ ,  $y_f$ , corresponding to an informal statement, an informal draft, the formal statement, and the formal full proof. For zero-shot prompting (possibly with ERP), we use the prompt template in Figure [8,](#page-14-2) which has two extra fields ps and  $y f_p$ . For non-ERP prompting, they are set to null string. For ERP prompting at state s, they corresponds to the 'proof state' s.state and the partial proof that have been verified at this state.

As to the chat template, we simply use three newlines to separate pairs of user-assistant messages and concatenate the user message and assistant message in each pair. Nevertheless, we mainly expect the response to stop at the end of the Isabelle code block.

Figure [7](#page-13-0) shows an example of the sampled 1-shot prompt.

```
"user": "Please complete the following Isabelle proof.\n'''isabelle\n(*
   Informal statement:\n{xi}\n\nInformal proof:\n{yi} *)\n{xf}\n",
"assistant": "\{vf\}\n''\n'\n'\n'',
"stop": ["'''", "\ntheorem", "\nend"]
```
Figure 6: The prompt template we use for few-shot prompting.

As to the choice of the number of shots to use, in [Jiang et al.](#page-8-11) [\(2023\)](#page-8-11), they set #shot=3 when prompting the model to translate a draft. We find that since the maximum sequence length of deepseek-math-7b-base is only 4096, few-shot prompting can lead to failure of proofs that are long in nature. As a consequence, DSP with 3-shots prompting solves 117/244, 2-shots 118/244, both smaller than 1-shot (120/244). Thus, across the paper, we use 1-shot prompting unless otherwise stated.

## <span id="page-12-1"></span>F. Breakdown of the Mixture of Strategies

Table [3](#page-14-1) shows the breakdown of the mixture of strategies in Section [4.3.](#page-6-0) Below are some explanations of the options appearing in Table [3.](#page-14-1)

As to the prompt version, we have 3 versions of few-shot prompting and two versions of zero-shot prompting. The three

```
Please complete the following Isabelle proof.
(* Informal statement:
When Rachel divides her favorite number by 7, she gets a remainder of 5.
What will the remainder be if she multiplies her favorite number by 5 and then divides by 7?
Show that it is 4.
Informal proof:
Let n be Rachel's favorite number. Then n \equiv 5 \pmod{7}, so 5n \equiv 5 \cdot 5 \equiv 25 \equiv 4 \pmod{7}. *)
theorem mathd_numbertheory_335:
  fixes n :: nat
  assumes h0 : "n mod 7 = 5"
  shows "(5 * n) \mod 7 = 4"
proof -
  (* so 5n ≡ 5 · 5 ≡ 25 ≡ 4 (mod 7). *)
  have c0: " (5 * n) \mod 7 = (5 * 5) \mod 7"proof -
    have c00: "(5 * n) mod 7 = (5 mod 7 * (n mod 7)) mod 7"by (auto simp: mod_simps)
    then show ?thesis unfolding h0
      by auto
  qed
  also have "... = 4 mod 7" by auto
 finally show ?thesis by auto
qed
Please complete the following Isabelle proof.
(* Informal statement:
{informal statement of the problem}
Informal proof:
{informal draft of the problem} *)
{formal statement of the problem}
```
Figure 7: An example of final 1-shot prompt for ProofAug.

versions of few-shot prompting share the same prompt template shown in Figure [6,](#page-12-2) but differ in examples: 'DSP' refers to the examples in [Jiang et al.](#page-8-11) [\(2023\)](#page-8-11), and 'few-shot' refers to examples used for ProofAug, where we write full proofs that strictly match the informal proofs provided in the miniF2F dataset of [Jiang et al.](#page-8-11) [\(2023\)](#page-8-11). In contrast, many of the informal proofs of DSP few-shot prompting examples are just descriptions of formal sketches prepared in advance. We also have a 'few-shot-legacy' version where we first write the simplest proof (rather than a proof sketch) we can come up for each theorem, then write a natural language description for it as an informal proof. Although it turns out that the 'few-shot' version is the best one for 1-shot prompting, the three sets of examples form a complement to each other. Since zero-shot prompting do not involve examples, the two versions of our zero-shot prompts only differ in the instruction text and format. For the 0-shot-legacy prompt, we do not have the 'Below is a complete proof of a statement in Isabelle/Isar, translated from the informal proof.' text in the "user" field shown in Figure [8.](#page-14-2)

 $A' \times'$  in the 'Draft' column means that informal statement and the informal proof are not included in the prompt.

For the experiments using the ERP module, we only count the proved theorem using fewer than 700 and 200 requests to the model, for the experiments with 500 attempts and 100 attempts, respectively. As to the pass rates of these experiments, since we only evaluate on the previously unproved theorems for the curated version dataset, we put N/As for them.

For further information, such as the contents of the examples, please refer to our code.

## G. Additional Experimental Results

On miniF2F-valid, ProofAug w/ and w/o ERP module achieve 58.6% and 57.0% in 100 attempts of proof respectively. During the experiment, we make sure the problem to prove is not in the candidate examples.

<span id="page-14-2"></span>{ "user": "Please complete the following Isabelle proof.\n'''isabelle\n(\* Informal statement: $\n\xi\in\mathcal{S}\n\rangle$  proof: $\n\{yi\} * \n\{xf\}\n\{yf_p\{ps\}".$ "assistant": " $\{yf_c\}\n'\iota'\n'\n''$ , "stop": ["'''", "\ntheorem", "\nend", "\nlemma"] }

<span id="page-14-1"></span>Figure 8: The prompt template we use for zero-shot prompting for efficient recursive proving (ERP) module.

#attempts	Prompt Ver.	$#$ shots	Draft	ERP	#queries	Curated Ver.	Pass Rate
500	$0$ -shot	0	$\times$	$\times$	500		N/A
500	$0$ -shot	$\Omega$			700	$\times$	57.4%

## <span id="page-14-0"></span>H. An Example of How ProofAug Induce a Proof

Figure [9](#page-15-0) shows an example of ProofAug inducing a proof from a failed proof proposal generated by the model. It can be seen that the initial proof fails inside the **proof...qed** block of proving  $a(2 - a) \le 1$  due to the wrong intermediate claim  $2*a-a^2 = (a-1)^2 + 1 - a^2$ . ProofAug finds that  $a(2-a) \le 1$  can be directly proved with the proof method sos given the previous proved fact  $(a-1)^2 \geq 0$ .

```
