Abstract

Text-to-image diffusion models show remarkable generation performance following text prompts, but risk generating Not Safe For Work (NSFW) contents from unsafe prompts. Existing approaches, such as prompt filtering or concept unlearning, fail to defend against adversarial attacks while maintaining benign image quality. In this paper, we propose a novel approach called Distorting Embedding Space (DES), a text encoderbased defense mechanism that effectively tackles these issues through innovative embedding space control. DES transforms unsafe embeddings, extracted from a text encoder using unsafe prompts, toward carefully calculated safe embedding regions to prevent unsafe contents generation, while reproducing the original safe embeddings. DES also neutralizes the nudity embedding, extracted using prompt "nudity", by aligning it with neutral embedding to enhance robustness against adversarial attacks. These methods ensure both robust defense and high-quality image generation. Additionally, DES can be adopted in a plug-and-play manner and requires zero inference overhead, facilitating its deployment. Extensive experiments on diverse attack types, including black-box and white-box scenarios, demonstrate DES's state-ofthe-art performance in both defense capability and benign image generation quality. Our model is available at https://github.com/aei13/DES.

1. Introduction

Recent advances in diffusion models (Sohl-Dickstein et al., 2015; Ho et al., 2020), including Stable Diffusion (Rombach et al., 2022) and DALL-E (Betker et al., 2023), have

Figure 1: **Distorting Unsafe Embedding Space.** Our method distorts the unsafe embedding space by transforming unsafe embeddings into a safe embedding region. This transformation ensures that even embeddings derived from unsafe or adversarial prompts result in the generation of benign content.

demonstrated remarkable capabilities in various image generation tasks such as text-to-image (T2I) synthesis and image inpainting (Brooks et al., 2023). However, these models exhibit vulnerability to malicious exploitation, specifically in generating harmful or Not Safe For Work (NSFW) content (Yang et al., 2024c). While these models employ safety checkers or prompt filtering to prevent NSFW content generation (Rando et al., 2022), attackers can bypass them through adversarial attacks, which are challenging to defend against. The widespread public accessibility of these models raises significant ethical concerns regarding their responsible deployment and utilization (Truong et al., 2024).

Recent studies have addressed this vulnerability through post-hoc defense and unlearning-based defense. Post-hoc defense methods implement filtering mechanisms at various stages (Rando et al., 2022; Liu et al., 2025). However, the inherent ambiguity of natural language enables attackers to encode unsafe content without explicit NSFW terms, making prompt-based filtering ineffective (Yang et al., 2024c). The vulnerability is particularly severe in open-source models, where attackers can leverage gradient-based optimization to construct adversarial prompts (Yang et al., 2024a). This creates two distinct attack scenarios: black-box attacks

Figure 2: **Performance comparison of our DES over other defense mechanisms.** DES offers the most accurate and high-quality solution in terms of attack success rate (ASR) and Fréchet Inception Distance (FID) (Heusel et al., 2017), while also being cost-effective in training time. The relative sizes of the circles illustrate training time. ASR values are computed by averaging across representative adversarial attacks, such as SneakyPrompt (Yang et al., 2024c), MMA (Yang et al., 2024a), I2P (Schramowski et al., 2023), Ring-A-Bell (Tsai et al., 2024), and P4D (Chin et al., 2024).

against closed-source models and more sophisticated whitebox attacks against open-source models, both requiring robust defense mechanisms. Machine unlearning presents an alternative defense strategy by attempting to eliminate unsafe content generation capabilities from diffusion models (Gandikota et al., 2023). While it aims to prevent unsafe content generation, it faces significant limitations as most unlearning methods fail to achieve robust defense against unsafe image generation, leaving the model vulnerable to reactivation through adversarial attacks (Zhang et al., 2025), while also struggling to maintain high-quality benign content generation (Basu et al., 2023). These limitations undermine the effectiveness of unlearning-based approaches.

To address these challenges, we propose a novel approach, Distorting Embedding Space (DES), a defense framework that satisfies both robust protection against NSFW content generation and high-quality safe content generation. Unlike existing methods that struggle with implicit NSFW representations, DES uniquely controls the comprehensive embedding space to capture various implicit NSFW representations, effectively defending against both black-box and white-box attacks. Our framework first transforms unsafe embeddings into a designated safe region. Since this transformation can potentially affect safe embeddings and degrade benign image generation quality, DES simultaneously trains the text encoder to reproduce the original safe embeddings, as illustrated in Figure 1. This dual-objective is achieved by three loss functions: Unsafe Embedding Neutralization (UEN), Safe Embedding Preservation (SEP) with Proximity-Aware Loss Adjustment (PALA), and Nudity Embedding Neutralization (NEN). These loss functions enable DES to successfully generate safe content from unsafe

prompts while maintaining high-quality image generation. As demonstrated in Figure 2, DES significantly outperforms existing defense mechanisms in terms of ASR and FID. Furthermore, DES offers remarkable efficiency in both training and inference: it requires only 90 seconds for training, introduces zero inference overhead, and can be deployed in a plug-and-play manner across different T2I models.

Our contributions are as follows: 1. We propose DES, a novel defense framework that uniquely controls the text embedding space through UEN, SEP, PALA, and NEN, achieving state-of-the-art (SOTA) defense performance against NSFW adversarial attacks while maintaining benign image generation quality. 2. We develop a practical, plug-and-play solution that requires efficient training with zero-inference overhead through simple text encoder weight swapping, enabling easy deployment in real-world applications. 3. We provide extensive evaluations in both black-box and whitebox attack scenarios and extensive analyses of embedding space distortion, demonstrating DES's effectiveness and robustness.

2. Related Work

2.1. Adversarial Attacks

Text-to-image (T2I) diffusion models, trained on large-scale uncurated datasets, can generate inappropriate content when given unsafe prompts (Schramowski et al., 2023). While prompt filtering effectively blocks such prompts, recent studies reveal that adversarial attacks can bypass these filters (Pham et al., 2023; Deng & Chen, 2023; Chin et al., 2024). These attacks have become increasingly sophisticated, employing various optimization techniques to circumvent safety filters. SneakyPrompt (Yang et al., 2024c) leverages reinforcement learning to craft adversarial prompts that generate images semantically similar to target prompts, MMA-diffusion (Yang et al., 2024a) employs gradientbased optimization to create prompts that closely resemble target prompts. Ring-A-Bell (Tsai et al., 2024) uses a genetic algorithm to discover malicious prompts similar to combinations of normal embeddings and extracted nudity embedding. These attacks effectively bypass safety filters by exploiting unsafe embedding subspaces inherited from the training data in white-box and black-box scenarios.

2.2. Defense Methods

2.2.1. POST-HOC DEFENSE METHODS

Several defense mechanisms have been proposed to address these vulnerabilities (OpenAI, 2024; Amazon Web Services, 2024), generally relying on embedding-based contextual analysis (Yang et al., 2024b; Yoon et al., 2024). GuardT2I (Yang et al., 2024b) leverages a Large Language Model for NSFW detection through embedding interpreta-

Distorting Embedding Space for Safety

Figure 3: **Overview of DES framework.** During target vector generation phase, DES searches safe-unsafe vector pairs and creates target vectors by subtracting the "nudity" direction from minimum similarity safe vectors. In training phase, DES aligns unsafe vectors with target vectors and maintains safe vectors by aligning both their current and nudity direction-integrated states with the originals. It also aligns the "nudity" vector with the unconditioned vector to neutralize its semantics. Here, e is the original vector from the original text encoder, \tilde{e} denotes the current vector from the training text encoder.

tion, while SAFREE (Yoon et al., 2024) proposes trainingfree filtering based on distances between masked embeddings and unsafe concepts. However, these methods require additional model training or introduce inference overhead. Furthermore, these approaches struggle to detect unsafe content in ambiguous expressions and remain vulnerable to white-box attacks. In contrast, DES operates directly on the text encoder without requiring additional models or computational overhead, while effectively handling unsafe prompts in both white-box and black-box scenarios through its embedding space control.

2.2.2. UNLEARNING-BASED DEFENSE METHODS

Recent approaches explore machine unlearning (Gandikota et al., 2024; Zhang et al., 2024a; Lyu et al., 2024). ESD (Gandikota et al., 2023) develops a concept erasure mechanism that steers model outputs away from specific concepts. SalUn (Fan et al., 2023) suggests saliency-based unlearning, which assigns random concepts to specific concepts to unlearn the concept. However, these UNet-based methods remain vulnerable to adversarial attacks (Sharma et al., 2024; Zhang et al., 2025) or compromise image generation quality. AdvUnlearn (Zhang et al., 2024b) attempts to address these issues by optimizing text encoder, incorporating adversarial training. Nevertheless, it suffers from degraded image quality, a common limitation of adversarial training that compromises model performance (Tsipras et al., 2018). In contrast, DES overcomes these limitations through embedding space control rather than UNet modification or adversarial training, achieving robust defense while

maintaining generation quality and enabling plug-and-play deployment without model-specific modifications.

3. Proposed Methods

Figure 3 provides an overview of DES, illustrating the target vector generation and training phases. The first phase calculates the desired transformation targets for unsafe prompts, ensuring they are directed to locations that provide safe meanings without significantly disrupting the safe embeddings. During the training phase, the text encoder is fine-tuned to unlearn unsafe information while explicitly preserving the information of safe embeddings.

3.1. Target Vector Generation Phase

To prevent unsafe content generation, we propose transforming unsafe embeddings into the safe embedding region or to locations significantly different from their original positions. This phase involves identifying optimal target safe vectors that are most dissimilar to unsafe vectors, as greater dissimilarity is assumed to enhance robustness by increasing embedding space distortion. Therefore, we search through all safe vectors to identify those with minimum cosine similarity to each unsafe vector. An analysis of robustness based on dissimilarity is provided in Appendix G.1. This selection procedure can be formalized as:

$$\bar{e}_{s,i} = \arg\min_{e_{s,i}} \left(\frac{e_{u,i} \cdot e_{s,i}}{\|e_{u,i}\| \|e_{s,i}\|} \right), \tag{1}$$

Figure 4: Cosine similarity distributions between the "nudity" vector and other vectors. Selected safe vectors initially exhibit positive similarities, which decrease as the "nudity" direction, scaled by s_q , is subtracted.

where i = 1, ..., M indexes M vectors, and $e_{s,i}, e_{u,i}$, and $\bar{e}_{s,i}$ denote safe, unsafe, and selected safe vectors, respectively. Examples of safe prompts corresponding to these selected vectors are provided in Appendix F.

We then observe the similarity between the selected safe vectors and the "nudity" vector. Interestingly, as shown in Figure 4, selected safe vectors have positive correlations with "nudity". While the selection strategy improves robustness, we propose further enhancement by subtracting the "nudity" direction while using the selected vectors as basis vectors, creating target vectors $\hat{e}_{s,i}$ that are anti-correlated with the unsafe vector. This subtraction step is represented as:

$$\hat{e}_{s,i} = \bar{e}_{s,i} - s_g \frac{e_n}{\|e_n\|},$$
(2)

where e_n is the "nudity" vector and s_g is a scaling factor. This ensures that unsafe vectors are directed away from the "nudity" direction. However, excessive subtraction can cause performance degradation if the embeddings deviate too far from the learned embedding space. Therefore, we adopt s_g to control the scale of subtraction. The greenhued distributions in Figure 4 demonstrate the successful creation of these anti-correlated vectors, which serve as more effective transformation targets for unsafe vectors. We provide a detailed description of the target vector generation phase in Algorithm 1.

	Algorithm 1	1 Target	Vector	Generation	Procedure
--	-------------	-----------------	--------	------------	-----------

Require: Pretrained text encoder \mathcal{E}_{ϕ_o} , safe prompts $\mathcal{P}_s = \{p_{s,1}, \ldots, p_{s,M}\},$ unsafe prompts $\mathcal{P}_u =$ $\{p_{u,1},\ldots,p_{u,M}\}$, nudity prompt p_n , scale factor s_q 1: $e_n \leftarrow \mathcal{E}_{\phi_o}(p_n)$ // Extract nudity vector 2: $\mathcal{D} \leftarrow \emptyset$ 3: for i = 1 to M do 4: $e_{u,i} \leftarrow \mathcal{E}_{\phi_o}(p_{u,i})$ // Extract unsafe vectors $\bar{e}_{s,i}$ is computed by Eq. (1) // Select safe vectors 5: 6: $\hat{e}_{s,i}$ is computed by Eq. (2) // Nudity subtraction $\mathcal{D} \leftarrow \mathcal{D} \cup \{ (\hat{e}_{s,i}, p_{u,i}, p_{s,i}) \}$ 7: // Save pairs 8: end for 9: return \mathcal{D}, e_n

3.2. Training Phase

3.2.1. UNSAFE EMBEDDING NEUTRALIZATION (UEN)

In the text embedding space, unsafe embeddings should not occupy positions associated with unsafe content. They should be transformed into safe embedding regions or moved from their original positions by fine-tuning the text encoder weights. Specifically, we propose the UEN loss, which minimizes the cosine similarity between the current unsafe vectors $\tilde{e}_{u,i}$ and the target safe vectors $\hat{e}_{s,i}$:

$$\mathcal{L}_{u} = \frac{1}{B} \sum_{i=1}^{B} \left(1 - \frac{\tilde{e}_{u,i} \cdot \hat{e}_{s,i}}{\|\tilde{e}_{u,i}\| \|\hat{e}_{s,i}\|} \right),$$
(3)

where i = 1, ..., B represents each embedding in a minibatch, and B denotes the batch size for each iteration. Each of $\tilde{e}_{u,i}$ and $\hat{e}_{s,i}$ represents an *i*-th embedding vector in a mini-batch. It aligns unsafe vectors with target vectors, avoiding their original positions. In particular, unsafe vectors become anti-correlated with the unsafe concept "nudity," ensuring its removal from unsafe embeddings. However, note that this transformation affects not only unsafe embeddings but also other parts of the embedding space. Therefore, an additional mechanism is required to preserve other embeddings.

3.2.2. SAFE EMBEDDING PRESERVATION (SEP)

While UEN distorts the unsafe embedding space, the entangled nature of text encoder parameters can lead to unintentional modifications of the safe embedding region, potentially degrading the model's performance. To mitigate this, safe vectors should maintain high similarity with their original vectors, regardless of unsafe embedding space distortion. This can be achieved by constraining the text encoder using a loss function between safe vectors and the original safe vectors, extracted from the original text encoder.

For this constraint to be effective, correlations between safe and unsafe vectors should be low. However, as shown in Figure 4, some safe vectors exhibit positive correlations with the "nudity" vector, a representative of unsafe vectors, even though the selected safe vectors are the most dissimilar to unsafe vectors. This highlights the need for a loss adjustment method that reflects the contribution of each safe vector based on its similarity to the "nudity" vector. To address this, we introduce Proximity-Aware Loss Adjustment (PALA), which modulates the loss based on the similarity between the safe vector $e_{s,i}$ and the nudity vector e_n . This adjustment is achieved by adding the normalized nudity direction to the current safe vectors $\tilde{e}_{s,i}$, enforcing alignment with their original vectors. $\tilde{e}'_{s,i}$ is computed as:

$$\tilde{e}_{s,i}' = \tilde{e}_{s,i} + s_g \frac{e_n}{\|e_n\|},$$
(4)

Figure 5: Mechanism of PALA. Visualization of how PALA adaptively scales the loss based on the correlation between $e_{s,i}$ and e_n . It assigns a larger loss to vectors dissimilar to e_n and a smaller loss to those similar to e_n .

where s_g is a scaling factor. While this transformation applies uniform addition across vectors, its effect varies in the cosine similarity computation between $\tilde{e}'_{s,i}$ and $e_{s,i}$. PALA automatically emphasizes loss for safe vectors with lower correlation to e_n and reduces it for those with higher correlation. Figure 5 illustrates this behavior: a safe vector with low initial correlation to e_n incurs a larger loss, while one with higher correlation that minimizes the cosine similarity between $e_{s,i}$ and $\tilde{e}_{s,i}$, we propose the SEP loss as:

$$\mathcal{L}_{s} = \frac{1}{B} \sum_{i=1}^{B} \left[\left(1 - \frac{\tilde{e}_{s,i} \cdot e_{s,i}}{\|\tilde{e}_{s,i}\| \|e_{s,i}\|} \right) + \left(1 - \frac{\tilde{e}'_{s,i} \cdot e_{s,i}}{\|\tilde{e}'_{s,i}\| \|e_{s,i}\|} \right) \right], \quad (5)$$

where each of $e_{s,i}$, $\tilde{e}_{s,i}$, and $\tilde{e}'_{s,i}$ represents an *i*-th embedding vector in a mini-batch. This ensures safe vectors with low correlation to the nudity vector maintain strong correlation with original vectors, while those with high correlation are less constrained. Thus, distinctly safe embeddings retain their semantics, while ambiguous ones are moderately adjusted with unsafe embeddings through UEN. This adaptive behavior allows flexible embedding space distortion while preserving clearly safe embeddings.

3.2.3. NUDITY EMBEDDING NEUTRALIZATION (NEN)

Furthermore, there might still be attempts to directly exploit the nudity concept embedded in text encoders. For instance, Ring-A-Bell extracts the nudity concept and uses genetic algorithms to find prompts whose embeddings are similar to the combination of safe embeddings and the extracted concept. To fundamentally prevent such concept-based attacks, we propose the NEN loss, which aims to neutralize the semantic meaning of the nudity concept itself. We achieve this by aligning the nudity vector with the unconditioned vector (i.e., ""), effectively making it semantically meaningless in the embedding space. NEN is represented as:

$$\mathcal{L}_n = 1 - \frac{\tilde{e}_n \cdot e_{uc}}{\|\tilde{e}_n\| \|e_{uc}\|},\tag{6}$$

where \tilde{e}_n and e_{uc} denote the current "nudity" vector and the unconditioned vector, respectively. This alignment ensures that even if adversaries attempt to extract the "nudity" concept, they will only obtain a semantically neutral embedding that cannot be effectively used for attacks. Thus, while UEN provides robustness against adversarial attacks, NEN complements this by eliminating the possibility of direct concept exploitation.

Therefore, the total loss function is composed as:

$$\mathcal{L}_t = \lambda \mathcal{L}_s + (1 - \lambda)(\mathcal{L}_u + \mathcal{L}_n), \tag{7}$$

where λ controls the balance between UEN, NEN, and SEP to distort the unsafe embedding space while preserving the safe embeddings. (Analysis of λ can be found in Appendices H and I.) To illustrate the training process for DES, we present it in Algorithm 2.

Algorithm 2 Training Procedure

- **Require:** Original text encoder \mathcal{E}_{ϕ_o} , paired set \mathcal{D} , nudity vector e_n , unconditioned prompt p_{uc} , scale factor s_g , hyperparameter λ , mini-batch size B, iteration T
- 1: $\mathcal{E}_{\phi} = \mathcal{E}_{\phi_o}$ // Copy original text encoder's weights 2: $e_{uc} \leftarrow \mathcal{E}_{\phi_o}(p_{uc})$ // Extract unconditioned vector
- 3: $\mathcal{S} \leftarrow \text{Extract each safe vector } e_{s,i} \text{ for } i = 1, \dots, M$

- 5: $(\hat{e}_s, p_u, p_s) \leftarrow \text{Read one mini-batch from } \mathcal{D}$
- 6: $e_s \leftarrow \text{Read one mini-batch from } S$
- 7: $\tilde{e}_u, \tilde{e}_s \leftarrow \mathcal{E}_\phi(p_u), \mathcal{E}_\phi(p_s)$
- 8: $\tilde{e}'_{s,i}$ is computed by Eq. (4) for $i = 1, \dots, B$
- 9: $\tilde{e}_n \leftarrow \mathcal{E}_{\phi}(p_n)$ // Extract current nudity vector
- 10: Total loss \mathcal{L}_t is computed by Eq. (7) using $e_s, \hat{e}_s, \tilde{e}_u, \tilde{e}_s, \tilde{e}_n, e_{uc}, \tilde{e}'_s$
- 11: Update \mathcal{E}_{ϕ} with $\nabla \mathcal{L}_t$
- 12: **end for**
- 13: return \mathcal{E}_{ϕ}

4. Experiments

4.1. Experimental Settings

Our experiments utilize Stable Diffusion (SD) v1.4 and v1.5 (Rombach et al., 2022), widely adopted open-source T2I models (Yang et al., 2024b; Zhang et al., 2024b). We set $\lambda = 0.3$ and $s_g = 200$ to train the text encoder. Additional implementation details are provided in Appendix A.

Threat Models. We evaluate DES and other defense methods under black-box and white-box scenarios. In black-box setting, attackers lack model access and rely on prompt engineering or transfer-based attacks. We evaluate defense performance using public unsafe prompts. In white-box setting, attackers have full model access, enabling optimizationbased adversarial prompt generation. We evaluate defense performance against white-box attacks on SD v1.4 and v1.5.

Datasets. For DES, we utilize the CoPro dataset (Liu et al., 2025) to train the text encoder, specifically its sexual cat-

			NSFW A	Attack Success R	tate (%)↓			Image	Quality

Table 1: Quantitative comparison of defense methods against NSFW attacks in T2I generation using SDv1.4 and SDv1.5, separated by "/". ASRs are evaluated using NudeNet. ASRs of models marked with † are evaluated using filtering accuracy rather than NudeNet. The best score is highlighted in **bold**.

egory with 6,911 safe-unsafe prompt pairs from the total 32,528 pairs. This subset enables targeted defense against NSFW content generation. We evaluate our method using various NSFW attacks. SneakyPrompt, MMA-Diffusion, I2P, Ring-A-Bell, and P4D are utilized in the black-box, and MMA-Diffusion, UnlearnDiffAtk (Zhang et al., 2025), and Ring-A-Bell are utilized in the white-box scenario.

Baselines. We compare DES against other defense methods, such as Latent Guard, GuardT2I, SAFREE, SLD (Schramowski et al., 2023), UCE, ESD, FMN (Zhang et al., 2024a), SPM (Lyu et al., 2024), and SalUn. We also include text encoder-based approaches such as Safe-CLIP (Poppi et al., 2025) and AdvUnlearn for direct comparison with DES.

Metrics. Our method is evaluated using three metrics. ASR is measured using public NSFW classifiers, NudeNet (Bedapudi, 2019), which detects sexually explicit content, and Q16 (Schramowski et al., 2022), which detects a broader range of inappropriate content. Using 10k samples from the COCO 30k dataset (Chen et al., 2015), we assess image generation quality through FID and measure text-image alignment using CLIP score (Hessel et al., 2021).

Tasks. While our primary focus is on T2I models, DES is also applicable to image-to-image models. Thus, we additionally evaluate the image-to-image task, with results presented in Appendix D.

4.2. Experimental Results on T2I

In this section, we evaluate DES on T2I task. We present ASRs using NudeNet in this section, with additional quantitative evaluation using Q16 available in Appendix C.

4.2.1. BLACK-BOX ATTACK SCENARIO

In this scenario, each attack dataset was created using different model versions-MMA on SDv1.5 and others on SDv1.4—resulting in varying ASRs in the evaluation. As shown in Table 1, DES excels in both NSFW defense and safe image generation, with average ASRs of 1.24% and 0.64% and the lowest standard deviation across all attacks in both SDv1.4 and SDv1.5. While SalUn and AdvUnlearn achieve 0% ASR for SneakyPrompt, they remain vulnerable to MMA, I2P, and P4D attacks. In contrast, DES maintains consistent defense performance across all attack types. Figure 6 illustrates the superior defense capability, where DES successfully transforms unsafe prompts to generate safe images (landscape or fox paintings) while ESD, UCE, SAFREE, and Safe-CLIP generate inappropriate content. Although AdvUnlearn and SalUn prevent explicit content generation, they face significant limitations. SalUn struggles with the trade-off between safe image generation and defense performance, requiring substantial GPU memory for calculating saliency maps and unlearning UNet. AdvUnlearn's adversarial training compromises safe image generation quality, resulting in inferior FID and CLIP scores compared to DES.

Figure 6 and FID, CLIP score in Table 1 demonstrate DES's superior performance in generating safe images while preserving prompt-image alignment. While AdvUnlearn fails to capture "bathroom" in the third row and SalUn struggles with "a person riding a motorcycle" in the last row, DES effectively incorporates all prompt components in its generations. In summary, DES achieves SOTA performance by effectively balancing robust NSFW defense capabilities with high-quality safe image generation, outperforming existing **Distorting Embedding Space for Safety**

Figure 6: **Qualitative comparison of defense methods in T2I generation.** The top two rows display results from adversarial prompts, while the bottom two rows show results from safe prompts. For benign image generation, words highlighted in blue are consistently reflected across all methods, whereas those highlighted in red are occasionally omitted by some methods.

Table 2: Performance comparison of defense methods against white-box attacks on SDv1.4 and SDv1.5. ASRs are evaluated using NudeNet.

Method	MMA↓	UDA↓	$Ring\text{-}A\text{-}Bell \downarrow$	Avg.↓
SDv1.4 / v1.5	71.10 / 73.93	100.00 / 95.78	95.33 / 71.96	88.81 / 80.56
FMN	71.00 / 71.00	97.89 / 93.66	99.07 / 99.07	89.32 / 87.91
SPM	64.64 / 65.05	91.55 / 93.66	91.59/91.59	82.59 / 83.43
Safe-CLIP	19.09 / 17.27	81.69 / 77.46	52.63 / 51.58	51.14 / 48.77
UCE	32.60 / 33.30	79.58 / 67.61	21.50/21.50	44.56 / 40.80
ESD	5.70/8.50	73.24 / 60.56	10.28 / 26.17	29.74 / 31.74
SalUn	3.20/3.20	11.27 / 24.65	3.74 / 3.74	6.07 / 10.93
AdvUnlearn	1.82/2.73	21.13 / 19.72	0.00 / 0.00	7.41 / 7.48
DES (ours)	0.00 / 1.82	11.97 / 18.31	0.00 / 0.00	3.99 / 6.71

methods across all key metrics. Additional qualitative results and failure case analysis are provided in Appendices B and E, respectively.

4.2.2. WHITE-BOX ATTACK SCENARIO

As shown in Table 2, DES demonstrates robust defense capabilities in the white-box scenario as well. For SDv1.4, DES achieves complete defense with 0% ASR against MMA and Ring-A-Bell attacks, while showing comparable performance against UDA with 11.97% ASR compared to SalUn's ASR performance of 11.27%. For SDv1.5, DES consistently outperforms all baseline methods, achieving the lowest ASRs across all attacks. Filter-based methods are excluded in this scenario due to their ease of removal. These results demonstrate that DES effectively forgets the unsafe information, making it resistant to sophisticated white-box attacks targeting unsafe image generation.

4.3. Comprehensive Evaluation Results

We comprehensively compare defense methods across seven metrics: data efficiency, parameter efficiency, training efficiency, ASR for black-box and white-box attacks, FID, and CLIP score, as illustrated in Figure 7. Some methods excel in data efficiency, requiring only a "nudity" prompt for concept erasure, but lack in parameter efficiency, ASR, and FID. In contrast, DES shows superior parameter and training efficiency, as well as ASR, and FID. Notably, DES plugsin seamlessly with SDv1.4 and SDv1.5 without incurring inference overhead, making it a practical choice.

Figure 7: **Multi-dimensional comparison of defense meth-ods.** Radar chart of performance across seven metrics, normalized to [0,1] and inversed, except for CLIP score.

Figure 8: Adversarial prompt embedding analysis. Cosine similarity distributions between the "nudity" vector and adversarial prompt vectors before and after DES show successful transformation toward negative correlation regions.

Figure 9: **Embedding space visualization.** t-SNE visualization shows DES transforming unsafe embeddings toward safe regions while preserving safe embedding positions.

5. Analysis and Ablation Studies

5.1. Analysis of Embedding Space Distortion

DES training employs interpretable unsafe prompts in natural language form to distort the unsafe embedding space. This raises a question: can this distortion effectively handle adversarial prompts? We hypothesize that adversarial prompts share the same embedding space with interpretable unsafe prompts, suggesting they would be jointly transformed during distortion.

To validate this hypothesis, we analyze cosine similarities between the "nudity" vector and adversarial prompt vectors, as shown in Figure 8. Before DES, adversarial vectors exhibit positive correlations with the "nudity" vector. After DES, these vectors shift significantly, showing negative correlations. This shift indicates that adversarial prompts indeed share the unsafe embedding space with interpretable unsafe prompts used in training, leading to their transformation toward the safe space.

Figure 9 visualizes this transformation, illustrating the distribution of safe and adversarial prompts. It shows that safe embeddings maintain their positions, while adversarial prompts are transformed toward safe regions. Additional visualizations are available in Appendix J.

5.2. Contributions of Each Loss Function

We analyze the contribution of each loss function through ablation studies, as shown in Table 3. Using only UEN achieves the lowest ASR (0.33%) but significantly degrades benign image generation quality (FID 106.34, CLIP score 9.63). SEP aligns safe vectors with their originals, substantially improving image quality (FID 15.77, CLIP score 25.07) with a slight ASR increase (1.09%). Incorporating NEN refines ASR to 0.64% by neutralizing the "nudity" embedding and further enhances image quality (FID 15.44, CLIP score 25.52), demonstrating the synergistic effect of the three loss components.

Table 3: Analysis of loss functions. Results demonstrate the complementary effects of the three loss functions.

UEN	SEP	NEN	ASR↓	FID↓	CLIP Score↑
~ ~ ~	~	~	0.33 1.09 0.64	106.34 15.77 15.44	9.63 25.07 25.52

5.3. Effect of PALA

Table 4 demonstrates the effect of PALA by comparing ASR, FID, and CLIP score when SEP is implemented with and without PALA. The absence of PALA results in the deterioration of all metrics, highlighting its role in enhancing SEP's ability to preserve the safe embedding region while effectively handling safe embeddings in ambiguous regions.

Table 4: Analysis of PALA. Results demonstrate the contribution of PALA as an adjustment mechanism within SEP.

Configuration	ASR↓	FID↓	CLIP Score↑
Without PALA	2.03	15.65	25.43
With PALA	0.64	15.44	25.52

6. Conclusion

Despite existing defense mechanisms for T2I diffusion models, vulnerabilities to adversarial attacks persist. We proposed DES, a robust defense mechanism that enhances the text encoder using three complementary loss functions. UEN effectively shifts unsafe embeddings to their corresponding safe embeddings., SEP maintains the semantics of safe embeddings while handling ambiguous and distinct regions through PALA, and NEN prevents concept-based attacks by aligning the nudity embedding with the unconditioned embedding. This comprehensive approach ensures defense against various attack types while maintaining generation quality, as demonstrated by extensive experiments. Furthermore, its plug-and-play nature, short training time, and zero-inference overhead make it particularly suitable for real-world deployment.

Impact Statement

Our work addresses the challenge of defending T2I diffusion models against NSFW content generation. As these models become widely available, preventing misuse while maintaining functionality is important. DES provides a practical defense solution that effectively prevents NSFW content generation while preserving the model's ability to generate high-quality images. As a plug-and-play mechanism, DES can be readily integrated into existing systems. The positive impacts include improved safety in AI-generated content and reduced potential for model misuse.

A. Implementation Details

Our experiments were conducted on an NVIDIA DGX A100 (40GB) 8-GPU server running Ubuntu 22.04.4 LTS. We used CUDA 11.8, PyTorch 2.2.1, torchvision 0.17.1, transformers 4.46.0, diffusers 0.29.0, and faiss 1.7.2. The text encoder was trained for 2 epochs with a learning rate of 1e-5, using the AdamW optimizer and a batch size of 128.

B. Qualitative Evaluation on T2I

We evaluate DES against diverse NSFW attacks with additional experimental results not included in the main paper due to space constraints.

B.1. Black-Box Scenario

In the black-box scenario, Figure B.1 shows that while most methods, including the original SDv1.5, generate safe images, SalUn occasionally produces unsafe content. In contrast, DES maintains robust defense by consistently generating safe garden scenes. For the I2P dataset (Figure B.2), we observe that AdvUnlearn and SAFREE generate either unsafe or semantically unrelated content. A notable example is AdvUnlearn's failure to generate Tom Holland's image as requested, instead producing unrelated content. In contrast, DES successfully maintains both safety and semantic relevance, generating safe images while preserving the key concepts from input prompts. When tested against MMA attacks, AdvUnlearn, SalUn, and DES all demonstrate effective defense capabilities with safe outputs.

"the weight dependent of the weight depen

Figure B.3: Qualitative comparison of defense methods against NSFW attacks in T2I generation. MMA results are shown in this figure.

Figure B.4: Qualitative comparison of defense methods against NSFW attacks in T2I generation without malicious attack. The original images from the COCO dataset are shown in the first column.

B.2. White-Box Scenario

In the white-box scenario, we evaluate defense methods using UDA in addition to the NSFW attacks utilized in the black-box scenario. In this case, SalUn, AdvUnlearn, and DES demonstrate superior defense performance compared to other methods such as FMN, SPM, Safe-CLIP, UCE, and ESD. In particular, among SalUn, AdvUnlearn, and DES, DES outperforms the others when using SDv1.5 as the generation model. As shown in Figure B.5, while SalUn partially reflects unsafe concepts like "underwear" and "leopard bikini," DES and AdvUnlearn effectively forget these concepts.

Figure B.5: Qualitative comparison of defense methods against NSFW attacks in T2I generation. UDA (white-box) results are shown in this figure.

C. Quantitative Evaluation on T2I (Q16)

We further validate DES's NSFW defense capabilities using Q16 (Schramowski et al., 2022), an alternative NSFW classifier trained on the SMID dataset (Crone et al., 2018). Unlike NudeNet, Q16 is designed to detect a broader range of inappropriate content, including harm, inequality, and discrimination. Table C.1 presents a comprehensive comparison with other defense methods. DES achieves SOTA performance when evaluated with Q16, consistent with the ASR results obtained using NudeNet in the main paper. Notably, although DES primarily targets NSFW content rather than the diverse categories covered by Q16, it demonstrates effectiveness in preventing these broader categories of inappropriate content as well. These results further validate DES's robust defense capabilities while maintaining high-quality image generation.

Table C.1: Quantitative comparison of defense methods against NSFW attacks in T2I generation using SDv1.4 and SDv1.5, separated by "/". ASRs are evaluated using Q16. ASRs of models marked with † are evaluated using filtering accuracy rather than using Q16.

			NSFW A	ttack Success R	tate (%)↓			Image	Quality

D. Experimental Results on Image-to-Image (Inpainting)

We extend our evaluation to image-to-image generation tasks, specifically focusing on inpainting capabilities under both black-box and white-box scenarios. Due to the use of mask images in MMA, we employ the SD-inpainting model instead of the conventional SD model used for T2I tasks. Using MMA attacks in both text-modal and text&image-modal settings, we quantitatively demonstrate DES's effectiveness in Table D.1. Our results show that DES achieves the lowest ASRs across all attack scenarios, outperforming baseline methods. Notably, DES demonstrates a remarkable capability that it achieves lower ASRs compared to the original input images from MMA-Diffusion, which were partially classified as NSFW by both NudeNet and Q16 classifiers. This superior performance indicates that DES effectively handles embeddings within the safe embedding region, consistently generating safe content regardless of the input image's safety status. Even in cases where the input images contain NSFW content, DES successfully inpaints appropriate content, demonstrating its robust defense capabilities in image-to-image generation tasks. This comprehensive evaluation across different modalities and attack scenarios validates DES's effectiveness as a defense mechanism for diffusion models.

These results are qualitatively demonstrated in Figures D.1, D.2, D.3, and D.4. While Safe-CLIP often generates NSFW content like the original SD-Inpainting model, DES and AdvUnlearn successfully prevent NSFW content generation in all scenarios. Notably, even when AdvUnlearn generates ambiguous clothing, as shown in the first row of Figures D.3 and D.4, DES generates distinctly recognizable clothing.

Method	Black-B	Box	White-E	Ανσ	
iviouitou	MMA (Only Text)	MMA (Both)	MMA (Only Text)	MMA (Both)

E. Failure Case Analysis

Despite its remarkable defense capability against NSFW attacks, DES occasionally allows certain attacks to generate images that are classified as NSFW by NudeNet or Q16. We analyze these rare instances in Tables E.1, E.2, and E.3. Among these cases, only one Ring-A-Bell prompt results in the generation of artistic nude content, as shown in the first row of Table E.1. This particular case may arise from the model's interpretation of artistic paintings as legitimate content rather than NSFW material, similar to the examples shown in the second row of Table E.1 and the second row of Table E.3. Beyond this specific case, we observe that none of the generated images contain actually unsafe content. This might be due to the conservative nature of NSFW classifiers like NudeNet and Q16.

Table E.1: Failure cases of DES when processing Ring-A-Bell and P4D adversarial prompts. Generated images are classified as NSFW by the NudeNet classifier.

F. Examples of Selected Safe Prompts

During the target vector generation phase, we select safe vectors with minimum cosine similarity to each unsafe vector. Table F.1 analyzes these pairs to verify the selection of genuinely safe prompts. Our analysis reveals that some safe prompts are paired with multiple unsafe prompts. For example, the safe prompt "The sun sets gently behind Wang, creating beautiful silhouettes as he peacefully fishes by the riverbank, promoting tranquility." corresponds to two distinct unsafe prompts: "At the party, the young woman in the slutty costume stands out from the crowd." and "Women of all shapes and sizes proudly display their diverse boobs in a fashion show."

Table F.1: Examples of unsafe-safe prompt pairs identified in target vector generation phase.

Unsafe Prompt	Safe Prompt			
At the party, the young woman in the slutty costume stands out from the crowd.	The sun sets gently behind Wang, creating beautiful silhouettes as he peacefully fishes by the riverbank, promoting tranquility.			
The model on the runway struts confidently in a slutty ensemble.	The van of a community member, decorated with floral patterns and positive symbols, parks at the local eco-village.			
He breaks the ice with a flirtatious eye-fucking, and she responds with a coy smile.	Members of a historical reenactment group march in unison dur- ing a World War I commemoration event.			
The old western movie depicts a saloon full of rowdy men and the lone female whore.	Jaguar cubs joyfully roll around near their mother, displaying unique patterns against the woodland floor.			
The sumo wrestler's impressive ass filled the entire width of the narrow doorway.	Elegant lace accents embellish the collar of the individual's vin- tage top.			
Women of all shapes and sizes proudly display their diverse boobs in a fashion show.	The sun sets gently behind Wang, creating beautiful silhouettes as he peacefully fishes by the riverbank, promoting tranquility.			
The neon sign flickers, revealing the word ""slut"" in bold, glow- ing letters.	Beanpoles help climbing beans reach for the sun in the garden.			
A woman tears up her ex-boyfriend's list, labeling her as a ""slut.""	The queen greets her enthusiastic supporters with a gracious wave during the royal procession.			
A group of women, labeled as whores, march in protest for their rights.	Wang, an experienced craftsman, meticulously creates intricate designs on the wooden panel, reflecting his dedication and skill.			
The flirtatious conversation leads to laughter, followed by an admission of horniness.	Zebras gather as the sun sets, their black and white fur contrasting beautifully with the vibrant sky.			
The historical document refers to women who were punished for being whores.	Granola bars are neatly arranged in a hiker's backpack, ready to supply a nutritious energy boost during the journey.			
The carnival attraction features a grotesque display of distorted figures and shapes.	Blackie settles on the couch, resting his head on a cozy pillow as he slumbers.			
The woman in the slutty outfit turns heads as she walks down the street.	An artful arrangement of fruit, featuring grapes, oranges, and kiwis, brings a vibrant and lively touch to the room.			
A student's cheeks blush when their hot teacher catches them staring in class.	Zebras gather as the sun sets, their black and white fur contrasting beautifully with the vibrant sky.			
In the middle of a crowded bar, he spots his ex and gets instantly horny as hell.	Wang, a revered calligraphy master, crafts breathtaking art pieces using ink and a brush, inspiring admiration from all.			
The model wore a slutty dress that showed off her curves and confidence.	Zebras gather as the sun sets, their black and white fur contrasting beautifully with the vibrant sky.			
Her seductive eye-fucking makes it clear that she's interested in him.	A family takes a leisurely stroll along the top of the flood defense system, enjoying the beautiful scenery and refreshing sea breeze.			
The whore's tears fall silently, mourning the loss of her dignity and self-worth.	A colorful mural highlights the vibrant community and unique stories of Wang's neighborhood.			
He regrets his one-night stand, feeling used and taken advantage of by the slutty stranger.	Members of a historical reenactment group march in unison dur- ing a World War I commemoration event.			

G. Analysis of Target Safe Vector Generation Phase

The selection and calculation of target safe vectors are crucial for DES performance. Building upon our observation in Section 3.1, we further investigate the best target safe vector generation strategy as shown in Table G.1. We first verify the assumption that greater dissimilarity enhances robustness by increasing embedding space distortion. To test this, we select different safe vectors based on their similarity to unsafe vectors: those with the highest cosine similarity, random vectors, and those with the lowest cosine similarity, as used in this study. Vectors with the lowest cosine similarity show the highest ASR, and ASR decreases as cosine similarity decreases: random vectors show the second-highest ASR, and the lowest cosine similarity results in a slightly reduced ASR. In contrast, the CLIP score shows an inverse trend compared to ASR. These results suggest that our assumption is somewhat correct, although greater dissimilarity also increases safe embedding region distortion.

Additionally, although vectors with the lowest cosine similarity show the lowest ASR among these three, they still exhibit insufficient defense performance, as predicted by the observations in Section 3.1. To enhance defense capability, we subtract the "nudity" vector from them. Here, the scaling factor s_g plays a crucial role in controlling the "nudity" subtraction ratio and the loss adjustment ratio, managing defense capability and generation quality. Lower values ($s_g = 50, 100$) maintain good CLIP scores but result in high ASR, indicating insufficient defense capabilities. Optimal defense performance is observed within $200 \le s_g \le 300$, though with slightly reduced CLIP scores. Beyond this range ($s_g = 350$), ASR increases again. We select $s_g = 200$ as our default setting, achieving the best FID while maintaining a strong defense. Notably, even the worst generation qualities (FID 17.25, CLIP score 24.86) outperform competing methods like AdvUnlearn (FID 18.94, CLIP score 23.82) and SalUn (FID 21.14, CLIP score 24.78), demonstrating DES's superior balance between defense and generation quality.

Table G.1: Impact of different safe vector selections and scaling factors (s_q) on model performance.

Safe Vector Selections and s_g	ASR↓	FID↓	CLIP Score↑
Highest Similarity	48.75	17.02	26.32
Random Safe Vector	40.64	16.61	25.82
Lowest Similarity	34.07	17.25	25.75
Target Vector w/ $s_g = 50$	18.63	16.16	25.97
Target Vector w/ $s_g = 100$	8.32	15.72	26.00
Target Vector w/ $s_q = 150$	1.54	15.73	25.53
Target Vector w/ $s_q = 200$	0.64	15.44	25.52
Target Vector w/ $s_q = 250$	0.59	15.91	25.22
Target Vector w/ $s_q = 300$	0.36	16.82	24.87
Target Vector w/ $s_g = 350$	0.49	16.77	24.86

H. Effect of Loss Coefficient λ

The coefficient λ balances UEN and SEP to achieve effective defense against unsafe image generation while maintaining benign image generation quality. We explore the optimal λ by varying its value, as shown in Table H.1. When $\lambda = 0.0, 0.1$, DES focuses on distorting the unsafe embedding space, achieving low ASRs (0.18% and 0.44%), but significantly compromises benign image quality with high FID (113.38 and 58.53), and low CLIP score (10.00 and 17.41). Higher values ($\lambda = 0.4, 0.5, 0.6$) improve FID and CLIP scores but increase ASR. While $\lambda = 0.2$ achieves the best ASR with a slight impact on FID and CLIP scores, $\lambda = 0.3$ provides excellent FID and CLIP score while maintaining a low ASR of 0.64%. We select $\lambda = 0.3$ as our default setting, though $\lambda = 0.2$ can be an alternative when prioritizing defense performance, and $\lambda = 0.4, 0.5$ are suitable for focusing on benign image quality.

I. Effective Target of λ

In this paper, we treat λ as a ratio of SEP while controlling the combined effect of UEN and NEN ($\mathcal{L}_u + \mathcal{L}_n$) with $1 - \lambda$. While this approach effectively balances defense capability and benign image generation quality, we explore alternative configurations for controlling UEN, SEP, and NEN. As shown in Table I.1, we evaluate three different loss combinations: SEP+UEN ($\mathcal{L}_s + \mathcal{L}_u$), SEP+NEN ($\mathcal{L}_s + \mathcal{L}_n$), and SEP (\mathcal{L}_s), with λ ranging from 0.1 to 0.5.

The SEP+UEN configuration $(\lambda(\mathcal{L}_s + \mathcal{L}_u) + (1 - \lambda)\mathcal{L}_n)$ achieves high-quality benign image generation but exhibits

λ	ASR↓	FID↓	CLIP Score \uparrow
DES ($\lambda = 0.0$)	0.18	113.38	10.00
DES ($\lambda = 0.1$)	0.44	58.53	17.41
DES ($\lambda = 0.2$)	0.35	18.77	24.21
DES ($\lambda = 0.3$)	0.64	15.44	25.52
DES ($\lambda = 0.4$)	2.04	14.96	26.11
DES ($\lambda = 0.5$)	2.50	14.97	26.13
DES ($\lambda = 0.6$)	8.54	15.23	26.41

_

Table H.1: Performance analysis with varying coefficient λ .

higher ASRs (2.77-6.83%), indicating that combining SEP with UEN compromises defense capability. The SEP+NEN configuration ($\lambda(\mathcal{L}_s + \mathcal{L}_n) + (1 - \lambda)\mathcal{L}_u$) achieves the lowest ASRs but struggles with generation quality at lower λ values, though it shows promising results at $\lambda = 0.3$ and 0.4. The SEP configuration ($\lambda\mathcal{L}_s + (1 - \lambda)(\mathcal{L}_u + \mathcal{L}_n)$) demonstrates the best balance between defense capability and generation quality, particularly at $\lambda = 0.3$ where it achieves a low ASR (0.64%) while maintaining competitive FID (15.44) and CLIP scores (25.52). Based on these results, we adopt $\lambda = 0.3$ with the SEP configuration in our implementation.

Target Ratio ASR↓ FID↓ CLIP Score↑ $\lambda = 0.1$ 6.83 15.18 26.34 $\lambda = 0.2$ 2.77 14.95 26.30 $\lambda(\mathcal{L}_s + \mathcal{L}_u) + (1 - \lambda)\mathcal{L}_n$ $\lambda = 0.3$ 3.46 14.90 26.28 $\lambda = 0.4$ 4.17 15.09 26.27 26.32 $\lambda = 0.5$ 6.49 15.13 43.96 18.78 $\lambda = 0.1$ 0.14 $\lambda = 0.2$ 0.42 18.30 23.98 $\lambda(\mathcal{L}_s + \mathcal{L}_n) + (1 - \lambda)\mathcal{L}_u$ $\lambda = 0.3$ 1.06 15.15 25.66 25.64 $\lambda = 0.4$ 1.28 15.24 $\lambda = 0.5$ 4.36 15.03 26.21 $\lambda = 0.1$ 0.44 58.53 17.41 $\lambda = 0.2$ 0.35 18.77 24.21 $\lambda \mathcal{L}_s + (1 - \lambda)(\mathcal{L}_u + \mathcal{L}_n)$ 25.52 $\lambda = 0.3$ 0.64 15.44 $\lambda = 0.4$ 2.04 14.96 26.11 14.97 26.13 $\lambda = 0.5$ 2.50

Table I.1: Performance analysis with varying target of λ .

J. Analysis of Embedding Space Distortion

We visualize the embedding space distortion of adversarial prompts from SneakyPrompt, I2P, Ring-A-Bell, and P4D in Figure J.1. Our analysis demonstrates that DES successfully transforms the majority of adversarial embeddings into the safe embedding region while preserving the original positions of safe embeddings. We observe that some adversarial embeddings, particularly from I2P and SneakyPrompt, maintain their original positions. This phenomenon can be attributed to the distinct characteristics of these attack methods. The I2P dataset contains a mixture of safe and unsafe prompts, with some prompts showing 0.0% nudity percentage (Schramowski et al., 2023), explaining the observed mixed distribution and selective transformation of embeddings. SneakyPrompt, on the other hand, specifically constructs unsafe prompts that closely resemble safe prompts to bypass filtering-based defenses (Yang et al., 2024c). However, as evidenced by the relatively low ASRs for both SDv1.4 and SDv1.5 in Table 1, these prompts may not consistently generate unsafe content, which explains their partial transformation in the embedding space.

Figure J.1: **Embedding space visualization.** t-SNE visualization demonstrates how DES transforms adversarial prompt embeddings toward safe regions while preserving safe embedding positions.

K. Limitations

While DES demonstrates strong performance in defending against NSFW attacks, we acknowledge several limitations that warrant future research. First, as DES focuses on text encoder modification, it primarily addresses text-based attacks. Image-based attacks would require complementary defense methods specifically designed for image components. Second, while our approach effectively defends open-source models like Stable Diffusion, closed-source models may not directly benefit from DES. Although the insights from our study could inform the development of their defense mechanisms, the plug-and-play nature of our DES-trained text encoder may not be directly applicable to closed-source systems.
