# Leafwise positive scalar curvature and the Rosenberg index

Guangxiang Su and Zelin Yi

#### Abstract

Let M be a closed spin manifold, in this paper, we show that if there is a foliation (M, F) and a Riemannian metric on M that has leafwise positive scalar curvature then the Rosenberg index of M is zero.

## 1 Introduction

Let M be a closed even dimensional spin Riemannian manifold,  $E \rightarrow M$  a unitary flat vector bundle, the famous Lichnerowicz formula reads

$$\mathsf{D}^{\mathsf{E},2} = -\Delta^{\mathsf{E}} + \frac{\mathsf{k}}{4}$$

where k is the scalar curvature of M. As a consequence, if M has positive scalar curvature then the twisted Dirac operator is invertible and therefore has zero Fredholm index. The Atiyah-Singer index theorem then implies the following theorem due to Lichnerowicz[Lic63].

**1.1 Theorem.** If M admits positive scalar curvature, then  $\langle \widehat{A}(M) \operatorname{ch}(E), [M] \rangle = 0$  for all unitary flat vector bundles E.

This theorem gives a topological obstruction to the existence of positive scalar curvature. Of course for each single flat vector bundle E, its Chern character ch(E) = 1 does not carry extra information. The Rosenberg index describes an universal obstruction to positive scalar curvature over all possible flat vector bundles E which does carry extra information.

Let M be the universal covering that can be viewed as a principal  $\pi_1(M)$ bundle over M, let E be the universal flat Hilbert  $C^*\pi_1(M)$ -module bundle given by the associated product  $\widetilde{M} \times_{\pi_1(M)} C^*\pi_1(M)$ .

**1.2 Definition.** Let  $D^E$  be the Dirac operator twisted by the universal flat Hilbert module bundle. The Rosenberg index  $[\alpha] \in K_0(C^*\pi_1(M))$  of M is defined to be the index of  $D^E$ .

Alternatively, the Rosenberg index can be described by using the machinery of KK-theory and Kasparov product. Let F be the smooth function  $F(x) = x(1 + x^2)^{-1/2}$  or any other smooth functions that tends to  $\pm 1$  as  $x \to \pm \infty$ . Write F(D) for the functional calculus of the Dirac operator, it determines an element

$$[C(M, S^{TM}), F(D)]$$

in the group  $KK(C(M), \mathbb{C})$ . On the other hand, the universal flat Hilbert module bundle  $E \to M$  determines a KK-theory element

(1.2) 
$$[C(M, E), 0]$$

in KK ( $\mathbb{C}$ , C(M)  $\otimes$  C<sup>\*</sup> $\pi_1(M)$ ). The Kasparov product of (1.2) with (1.1) is precisely the Rosenberg index of M.

On the other hand, if M is of odd dimensional, then  $M \times S^1$  is a closed spin manifold of even dimensional and

$$\mathsf{K}_{0}\left(\mathsf{C}^{*}\pi_{1}(\mathsf{M})\times\mathbb{Z}\right)=\mathsf{K}_{0}(\mathsf{C}^{*}\pi_{1}(\mathsf{M}))\otimes\mathbb{1}\oplus\mathsf{K}_{1}(\mathsf{C}^{*}\pi_{1}(\mathsf{M}))\otimes e,$$

where 1 is the generator of  $K_0(C^*\mathbb{Z})$  and *e* is the generator of  $K_1(C^*\mathbb{Z})$ . Then the Rosenberg index of M is defined by the requirement

(1.3) 
$$\alpha(M) \otimes e = \alpha(M \times S^1).$$

The following result is the universal version of Theorem 1.1 for flat vector bundles.

**1.3 Theorem.** [*Ros86*] If M admits positive scalar curvature, then its Rosenberg index  $[\alpha]$  is zero.

**1.4 Remark.** According to the definition of Rosenberg index in the odd dimensional case, it suffices to prove the theorem in the even dimensional case.

If, now, (M, F) is foliated, it is natural to ask for obstructions to leafwise positive scalar curvature. Notably the following theorem is first proved by Connes[Con86] in the case when F is spin and later generalized by Zhang[Zha17] to the case when M is spin.

**1.5 Theorem.** Let F be an integrable subbundle of the tangent bundle of closed oriented smooth manifolds M. If either F or TM is spin and F carries leafwise positive scalar curvature then  $\langle \hat{A}(M), [M] \rangle = 0$ .

#### 1.1 Main Theorem

In this paper, we shall prove the following result.

**1.6 Theorem.** *If* M *is a foliated closed spin manifold with leafwise positive scalar curvature, then its Rosenberg index is zero.* 

According to Remark 1.4, we shall only prove the main theorem in the even dimensional case. In addition to the main theorem, we want to point out that if M is not necessarily spin and F is spin, the authors have defined the foliation version of Rosenberg index in [SY] and proved that it is an obstruction to leafwise positive scalar curvature.

#### **1.2** Outline of the proof

Let (M, F) be a foliated closed spin manifold of dimension m, the corresponding Connes fibration([Con86])  $\mathcal{M}$  is defined to be the space of Euclidean metrics on TM/F. Let k be the rank of TM/F. There is a natural projection  $p : \mathcal{M} \to \mathcal{M}$  whose typical fiber is the symmetric space  $GL^+(k, \mathbb{R})/SO(k)$ . The tangent space of the symmetric space at identity is the space of all symmetric matrices and denoted by  $\mathfrak{p}$ . As a consequence, there is a left invariant Riemannian metric on  $GL^+(k, \mathbb{R})/SO(k)$  given by the Killing form  $(X, Y) \mapsto Tr(XY)$ . By choosing a distinguished Euclidean metric  $g^{TM/F}$  on TM/F, we fix an embedding  $\mathcal{M} \hookrightarrow \mathcal{M}$ .

As shown in [Zha17], by using the Bott connection, the foliation (M, F) can be lifted to the Connes' fibration  $(\mathcal{M}, \mathcal{F})$ , the metric  $g^F$  on F can also be lifted to a metric  $g^{\mathcal{F}}$  on  $\mathcal{F}$ . The vertical tangent bundle of  $p : \mathcal{M} \to M$  is denoted by  $\mathcal{F}_2^{\perp}$ , the Riemannian metric on the symmetric space  $GL^+(k, \mathbb{R})/SO(k)$  induces a metric

 $g^{\mathcal{F}_2^{\perp}}$  on  $\mathcal{F}_2^{\perp}$ . The Euclidean metric  $g^{\mathsf{TM}/\mathsf{F}}$  that we use to determine the embedding  $M \hookrightarrow \mathcal{M}$  induces a metric  $g^{\mathcal{F}_1^{\perp}}$  on the quotient bundle  $\mathcal{F}_1^{\perp} = (\mathsf{T}\mathcal{M}/\mathcal{F})/\mathcal{F}_2^{\perp}$ . In fact, we shall need a more concrete description of  $\mathcal{F}_1^{\perp}$  (given in Remark 3.1) to fix a decomposition

(1.4) 
$$\mathsf{T}\mathcal{M} = \mathcal{F} \oplus \mathcal{F}_1^{\perp} \oplus \mathcal{F}_2^{\perp}.$$

Then  $T\mathcal{M}$  can be given a family of Riemannian structures

(1.5) 
$$g_{\beta,\varepsilon}^{T\mathcal{M}} = \beta^2 g^{\mathcal{F}} \oplus \frac{1}{\varepsilon^2} g^{\mathcal{F}_1^{\perp}} \oplus g^{\mathcal{F}_2^{\perp}}$$

for  $\beta$ ,  $\varepsilon > 0$ . We shall write  $g^{TM}$  for the one with  $\beta = 1$  and  $\varepsilon = 1$ . By restricting (1.4) to M, we have an orthogonal splitting

(1.6) 
$$T\mathcal{M}|_{M} = TM \oplus N,$$

where  $\pi : \mathbb{N} \to M$  is the normal bundle of M inside M and  $\pi$  is the bundle projection. If the normal bundle  $\mathbb{N}$  and the vertical tangent bundle  $\mathcal{F}_2^{\perp}$  are not spin, one may modify the definition of Connes fibration in the following way.

Let  $\mathcal{M}'$  be the space of Euclidean metrics on  $TM/F \oplus TM/F \to M$  that make two copies of TM/F orthogonal to each other. Again, a choice of Euclidean metric on TM/F determines an embedding  $\mathcal{M} \hookrightarrow \mathcal{M}'$ . Then the orthogonal splitting (1.6) becomes

$$\mathsf{T}\mathcal{M}'|_{\mathsf{M}}=\mathsf{T}\mathsf{M}\oplus\mathsf{N}\oplus\mathsf{N},$$

and the vertical tangent bundle of  $\mathcal{M}'$  becomes  $\mathcal{F}_2^{\perp} \oplus \mathcal{F}_2^{\perp}$ . From now on, we shall assume that the normal bundle and the vertical tangent bundle are both spin.

Let n be the dimension of the total space of  $\mathcal{M}$ . Let  $M \supset O \rightarrow \mathbb{R}^m$  be any local coordinate chart, locally the normal bundle can be trivialized by parallel sections. Under this light, we shall write

(1.7) 
$$(y, Z) = (y_1, \cdots, y_m, Z_{m+1}, \cdots, Z_n)$$

for a typical point in  $\pi^{-1}(O)$ . The Riemannian structure on the symmetric space determines the fiberwise exponential map

$$(1.8) \qquad \qquad \exp:\mathcal{U}\to U$$

that sends (y, Z) to  $\exp_y(Z)$  where  $\exp_y(Z)$  is the exponential map along the fiber of  $p : \mathcal{M} \to \mathcal{M}$ . It is an isomorphism between an open neighborhood U of M inside  $\mathcal{M}$  and an open neighborhood  $\mathcal{U}$  of the zero section in N.

For any point  $x \in \mathcal{M}$  there is a unique geodesic along the fiber of  $p : \mathcal{M} \to \mathcal{M}$  connecting p(x) with x whose length is denoted by  $\ell(x)$  and whose unit tangent vector at x is denoted by  $\nu(x)$ . Let  $V(x) = \ell(x)\nu(x)$ , then V can be viewed as a section of  $\mathcal{F}_2^{\perp} \to \mathcal{M}$ . It is straightforward to see that under local coordinate chart

(1.9) 
$$V(y,Z) = \sum_{i=m+1}^{n} Z_i \partial_{Z_i} = Z$$

for all  $(y, Z) \in \mathcal{U}$ .

There is a natural map  $C(M) \rightarrow C(M)$  whose image consists of those smooth functions that are constant along fibers, then the space  $C_0(M)$  is a C(M)-module. Now the pair

(1.10) 
$$\left[\mathsf{C}_{0}\left(\mathcal{M},\mathsf{S}(\mathcal{F}_{2}^{\perp})\right),\mathsf{c}(\mathsf{v})\right]$$

determines an element in  $KK(C(M), C_0(\mathcal{M}))$  (see also [Con86, Section 5]). Let  $D^{\mathcal{M}}_{\beta, \varepsilon}$  be the Dirac operator on the spinor bundle  $S^{T\mathcal{M}} \to \mathcal{M}$  with respect to the metric  $g^{T\mathcal{M}}_{\beta, \varepsilon}$ . Then, the pair

(1.11) 
$$[L^{2}(\mathcal{M}, S^{\mathsf{T}\mathcal{M}}), \mathsf{F}(\mathsf{D}_{\beta,\varepsilon}^{\mathcal{M}})]$$

determines an element in KK( $C_0(\mathcal{M}), \mathbb{C}$ )(see also [HR00]) and the class is independent of the choice of parameters  $\beta$ ,  $\varepsilon$ . Let  $D_{S(\mathcal{F}_2^{\perp}),\beta,\varepsilon}$  be Liu-Zhang's sub-Dirac operator([Zha17] see also [LZ01]) on  $S(\mathcal{F} \oplus \mathcal{F}_1^{\perp}) \otimes \wedge^* \mathcal{F}_2^{\perp} \to \mathcal{M}$  which, in our case, is precisely the twisted Dirac operator by another copy of  $S(\mathcal{F}_2^{\perp})$ .

We shall first show that the Kasparov product

$$\mathsf{KK}(\mathsf{C}(\mathsf{M}),\mathsf{C}_0(\mathcal{M}))\otimes\mathsf{KK}(\mathsf{C}_0(\mathcal{M}),\mathbb{C})\to\mathsf{KK}(\mathsf{C}(\mathsf{M}),\mathbb{C})$$

of (1.10) and (1.11) can be represented by the Kasparov module

(1.12) 
$$\left[ L^{2}(\mathcal{M}, S(\mathcal{F} \oplus \mathcal{F}_{1}^{\perp}) \otimes \wedge^{*} \mathcal{F}_{2}^{\perp}), F(D_{S(\mathcal{F}_{2}^{\perp}), \beta, \varepsilon} + T\hat{c}(V)) \right],$$

for all positive T. Moreover, by methods of analytic localization[BL91], the above Kasparov module is shown to be equivalent to a direct sum

(1.13) 
$$[C(M, S^{TM}), F(D)] \oplus [H_{T,4}, F(A_{T,4})]$$

where  $H_{T,4}$  is an appropriate Hilbert space that depends on T and parameters  $\beta$ ,  $\varepsilon$ , and  $A_{T,4}$  is an operator on  $H_{T,4}$  with compact resolvent and  $F(A_{T,4})$  is the corresponding functional calculus. These ingredients will be explained in due course. By definition, the Kasparov product of (1.2) with the first summand in (1.13) is the Rosenberg index of M and the Kasparov product of (1.2) with the second summand in (1.13) will be shown to be zero. As a result, the Kasparov product (1.14)

$$\mathsf{KK}(\mathbb{C},\mathsf{C}(\mathsf{M})\otimes\mathsf{C}^*\pi_1(\mathsf{M}))\otimes\mathsf{KK}(\mathsf{C}(\mathsf{M}),\mathsf{C}_0(\mathcal{M}))\otimes\mathsf{KK}(\mathsf{C}_0(\mathcal{M}),\mathbb{C})\to\mathsf{K}_0(\mathsf{C}^*\pi_1)$$

of (1.2), (1.10) and (1.11) is precisely the Rosenberg index of M. On the other hand, with leafwise positive scalar curvature, by carefully choosing  $\beta$ ,  $\varepsilon$  and T, one can make  $D_{S(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon} + T\widehat{c}(V)$  an invertible operator. This would implies that (1.14) is zero which finish the whole proof.

#### **1.3** Organization of the paper

The paper is organized as follows: in Section 2 we collect some basic Sobolev space and elliptic regularity results for noncompact manifolds; in Section 3 we prove that the Kasparov product of (1.10) and (1.11) is given by (1.12); in Section 4 we use Bismut-Lebeau analytic localization technique to decompose the operator

 $D_{S(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon} + T\widehat{c}(V)$  into a two by two matrix  $\begin{bmatrix} A_{T,1} & A_{T,2} \\ A_{T,3} & A_{T,4} \end{bmatrix}$  and collect various estimates for each of the four entries. Nearly all these estimates can be found in [BL91, Chapter 8 and 9]; As a consequence, we shall able to prove that the Kasparov module (1.12) is equivalent to (1.13) and the Kasparov product (1.14) is the Rosenberg index of M in Section 5. Finally, in Section 6, we shall prove that (1.14) is zero in the presence of leafwise positive scalar curvature.

#### 2 Sobolev space and elliptic regularity

Let  $\mathcal{M}$  be a noncompact manifold, let  $E \to \mathcal{M}$  be a Hermitian vector bundle with connection  $\nabla$ . The completion of the space  $C_c^{\infty}(\mathcal{M}, E)$  with respect to the norm

(2.1) 
$$\|f\|_{H^k}^2 = \|f\|_{L^2}^2 + \|\nabla f\|_{L^2}^2 + \dots + \|\nabla^k f\|_{L^2}^2$$

is denoted by  $H^k(\mathcal{M}, E)$  and is called k-th Sobolev space. Let  $D : C^\infty_c(\mathcal{M}, E) \to C^\infty_c(\mathcal{M}, E)$  be a differential operator on  $E \to \mathcal{M}$ . If  $O \subset \mathcal{M}$  is an open subset, then we shall say that D is elliptic over O if its restriction to O is elliptic in the sense that its symbol is invertible outside the zero section of the cotangent bundle. Of course, we shall say that D is elliptic if one can pick  $O = \mathcal{M}$ . If  $\mathcal{M}$  was compact, then the sobolev spaces  $H^k(\mathcal{M}, E)$  are independent of the choice of metrics and connections on E. On the other hand, if  $\mathcal{M}$  is noncompact, as in our case, the spaces  $H^k$  are indeed dependent of the choice of metrics and connections. If  $K \subset \mathcal{M}$  is a compact subset, the Sobolev space  $H^k(K, E)$  is defined to be the completion of

$$\{f \in C_c^{\infty}(\mathcal{M}, E) \mid supp(f) \subset K\}$$

with respect to the norm (2.1). This space is well-defined and, in fact, independent of the choice of metrics and connections. Moreover, we have the following versions of Rellich lemma and Garding's inequality.

**2.1 Proposition.** ([HR00, Section 10.4.3], [Aub98, Theorem 2.34]) The inclusion  $H^1(K, E) \hookrightarrow L^2(\mathcal{M}, E)$  is a compact operator for all compact subset  $K \subset \mathcal{M}$ .

**2.2 Proposition.** [HR00, Section 10.4.4] Let D be a first order differential operator on  $\mathcal{M}$  and let K be any compact subset of  $\mathcal{M}$ . If D is elliptic over a neighborhood of K, then there is a constant C > 0 such that

(2.2)  $\|u\|_{L^{2}(\mathcal{M},E)} + \|Du\|_{L^{2}(\mathcal{M},E)} \ge C \cdot \|u\|_{H^{1}(K,E)}$ 

for all  $u \in H^1(K, E)$ .

# 3 Kasparov product

Let  $\nabla^{T\mathcal{M}}$  be the Levi-Civita connection on  $\mathcal{M}$  with respect to  $g^{T\mathcal{M}}$ , and  $\nabla^{T\mathcal{M}|_{\mathcal{M}}}$  be the induced connection on restricted bundle  $T\mathcal{M}|_{\mathcal{M}}$ . Let  $p^{N}$  and  $p^{T\mathcal{M}}$  be the projections onto the two components of  $T\mathcal{M}|_{\mathcal{M}} = T\mathcal{M} \oplus N$ , and let  $p^{\mathcal{F} \oplus \mathcal{F}_{1}^{\perp}}$  and  $p^{\mathcal{F}_{2}^{\perp}}$  be the projections with respect to the decomposition (1.4). Let

(3.1) 
$$\nabla^{\mathsf{N}} = \mathfrak{p}^{\mathsf{N}} \nabla^{\mathsf{T}\mathcal{M}|_{\mathsf{M}}} \mathfrak{p}^{\mathsf{N}}, \quad \nabla^{\mathsf{T}\mathsf{M}} = \mathfrak{p}^{\mathsf{T}\mathsf{M}} \nabla^{\mathsf{T}\mathcal{M}|_{\mathsf{M}}} \mathfrak{p}^{\mathsf{T}\mathsf{M}},$$

and

$$\nabla^{\mathcal{F}\oplus\mathcal{F}_1^\perp}=p^{\mathcal{F}\oplus\mathcal{F}_1^\perp}\nabla^{\mathsf{T}\mathcal{M}}p^{\mathcal{F}\oplus\mathcal{F}_1^\perp},\quad \nabla^{\mathcal{F}_2^\perp}=p^{\mathcal{F}_2^\perp}\nabla^{\mathsf{T}\mathcal{M}}p^{\mathcal{F}_2^\perp}.$$

These connections can be lifted to corresponding connections on spinor bundles  $\nabla^{S(T\mathcal{M})}, \nabla^{S(\mathcal{F}\oplus\mathcal{F}_{1}^{\perp})}$  and  $\nabla^{S(\mathcal{F}_{2}^{\perp})}$ . Let  $\nabla^{S(\mathcal{F}\oplus\mathcal{F}_{1}^{\perp})\otimes\wedge^{*}\mathcal{F}_{2}^{\perp}}$  be the tensor product connection given by

$$abla^{\mathbf{S}(\mathsf{T}\mathcal{M})}\otimes 1+1\otimes 
abla^{\mathbf{S}(\mathcal{F}_2^{\perp})}.$$

We shall add superscript  $\beta$ ,  $\varepsilon$  to these notations to indicate the change of metrics from  $g^{T\mathcal{M}}$  to  $g^{T\mathcal{M}}_{\beta,\varepsilon}$ . For example  $\nabla^{S(T\mathcal{M}),\beta,\varepsilon}$  and  $\nabla^{S(\mathcal{F}\oplus\mathcal{F}_1^{\perp})\otimes\wedge^*\mathcal{F}_2^{\perp},\beta,\varepsilon}$ .

In fact, this is a general principle for our notations: we shall add sometimes superscript and sometimes subscript  $\beta$ ,  $\varepsilon$  to indicate the change from  $g^{TM}$  to  $g^{TM}_{\beta,\varepsilon}$ .

**3.1 Remark.** Let  $O_i \xrightarrow{\phi_i} \mathbb{R}^m$  be a finite set of local coordinate charts that covers M and the quotient bundle TM/F is trivial over each  $O_i$ . We shall denote by  $\varphi_{ij} = \varphi_i \circ \varphi_j^{-1}$  the change-of-coordinates function. Fix local trivializations  $\psi_i : TM/F|_{O_i} \to O_i \times \mathbb{R}^k$  and transition functions  $\psi_{ij} = \psi_i \circ \psi_j^{-1} : O_i \cap O_j \to GL(k, \mathbb{R})$ . Then the restriction of  $\mathcal{M}$  over  $O_i$  is diffeomorphic to  $O_i \times GL(k, \mathbb{R})^+/SO(k)$ . The change-of-coordinates function by

$$O_{i} \cap O_{j} \times GL(k, \mathbb{R})^{+} / SO(k) \to O_{i} \cap O_{j} \times GL(k, \mathbb{R})^{+} / SO(k)$$
$$(x, g) \mapsto (\varphi_{ij}(x), \Gamma(\psi_{ij}(x))g),$$

where  $\Gamma(\psi_{ij}(x))$  acts on the space of Euclidean metrics by  $\Gamma(\psi_{ij}(x))g)(X,Y) = g\left(\psi_{ij}^{-1}X,\psi_{ij}^{-1}Y\right)$  for all  $X,Y \in \mathbb{R}^k$ . The tangent bundle of  $\mathcal{M}$  is given by assembly local trivializations

$$O_i \times GL(k, \mathbb{R})^+ / SO(k) \times \mathbb{R}^m \times \mathfrak{p}$$

according to transition functions

(

$$O_{\mathfrak{i}} \cap O_{\mathfrak{j}} \times GL(k,\mathbb{R})^{+}/\operatorname{SO}(k) \times \mathbb{R}^{\mathfrak{m}} \times \mathfrak{p} \to O_{\mathfrak{i}} \cap O_{\mathfrak{j}} \times GL(k,\mathbb{R})^{+}/\operatorname{SO}(k) \times \mathbb{R}^{\mathfrak{m}} \times \mathfrak{p}$$

given by sending (x, g, X, Y) to  $(\varphi_{ij}(x), \Gamma(\psi_{ij}(x))g, d\varphi_{ij}(x)X, d\Gamma(\psi_{ij}(x))Y)$ . The vector bundle  $\mathcal{F}_1^{\perp}$  can be taken as assembly local trivializations

$$O_i \times GL(k, \mathbb{R})^+ / SO(k) \times \mathbb{R}^k$$

according to the transition function sending (x, g, X) to  $(\varphi_{ij}(x), \Gamma(\psi_{ij}(x))g, \psi_{ij}(x)X)$ .

**3.2 Proposition.** Recall that  $\ell(x)$  is the length of the geodesic connecting x and p(x) and v is the unit tangent vector at  $x \in M$  along the geodesic. Under the Riemannian metric  $g^{TM}$ , we have

- 1. The directional derivatives Xℓ are uniformly bounded with respect to all unit tangent vectors X of M;
- 2. The covariant derivatives  $\nabla_{X}^{\mathcal{F}_{2}^{\perp}} v$  are uniformly bounded with respect to all unit tangent vectors X of  $\mathcal{M}$ ;
- 3. The covariant derivatives  $\nabla_{X}^{\mathcal{F}_{2}^{\perp}}(\ell v)$  are uniformly bounded with respect to all unit leafwise tangent vectors  $X \in C^{\infty}(\mathcal{M}, \mathcal{F})$ .

*Proof.* Notice that the third part of the proposition is precisely [Zha17, Lemma 2.1], we shall only prove the first two parts of the proposition.

Let  $\{O_i\}$  be a finite open cover of M as given in Remark 3.1 By fixing an Euclidean metric on TM/F, there are embeddings  $O_i \hookrightarrow O_i \times GL(k, \mathbb{R})^+ / SO(k)$  given by smooth functions  $f_i : O_i \to GL(k, \mathbb{R})^+ / SO(k)$ . Let X be an unit vertical tangent vector at  $(u, g) \in \mathcal{M}|_{O_i}$ , then the directional derivative of  $\ell$  with respect to X is given by

$$\lim_{t\to 0}\frac{\ell(\mathfrak{u},\phi_t^{X}(\mathfrak{g}))-\ell(\mathfrak{u},\mathfrak{g})}{t}.$$

According to the definition,

$$\ell(\mathfrak{u},\mathfrak{g})=\mathfrak{d}(\mathfrak{g},\mathfrak{f}_{\mathfrak{i}}(\mathfrak{u})),$$

where d is the distance along the symmetric space  $GL(k, \mathbb{R})^+/SO(k)$ . The numerator above is less than or equal to  $d(g, \varphi_t^X(g))$  which is  $\leq 2t$  for sufficiently small t. By parallel translating the vertical tangent vectors X and v back to f(u) along the fibers, they can be identified with symmetric matrices for which we shall use the notations  $\widetilde{X}$  and  $\widetilde{v}$ . Since X and v are both vertical, the covariant derivative  $\nabla_X^{\mathcal{F}_2^{\perp}} v$  coincides with the Levi-Civita connection  $\nabla_X^{\mathcal{F}_2^{\perp}} v = \frac{1}{2} [\widetilde{v}, \widetilde{X}]$  of the symmetric space. Now if  $\widetilde{X}$  and  $\widetilde{v}$  satisfy  $\operatorname{Tr}(\widetilde{X}^2) = \operatorname{Tr}(\widetilde{v}^2) = 1$ , then  $\operatorname{Tr}([\widetilde{v}, \widetilde{X}]^2)$  is uniformly bounded. This completes the proof for vertical tangent vectors X.

If X is a local unit section of  $\mathcal{F}_1^{\perp} \to \mathcal{M}$ , according to the above Remark 3.1, under the local trivialization we may assume that X = (Y, 0) where Y is a local unit section of  $p^*TM/F \to \mathcal{M}$ . Then the directional derivative of  $\ell$  with respect to X is given by

$$\lim_{t\to 0} \frac{\ell(\varphi_t^Y(u),g)-\ell(u,g)}{t} \leq \lim_{t\to 0} \frac{d(f_i(\varphi_t^Y(u)),f_i(u))}{t}.$$

The limit is precisely the length of pushforward of Y by f<sub>i</sub>, which is also uniformly bounded.

As for the covariant derivative  $\nabla_X^{\mathcal{F}_2^{\perp}} v$ , let W be a symmetric matrix and taken as a vertical tangent vector of  $\mathcal{M}$ . According to the definition of Levi-Civita connection

$$2\langle \nabla_{\mathbf{Y}}^{\mathcal{F}_{2}^{\perp}} \boldsymbol{\nu}, W \rangle = \mathbf{Y} \langle \boldsymbol{\nu}, W \rangle + \langle W, [\mathbf{Y}, \boldsymbol{\nu}] \rangle + \langle \boldsymbol{\nu}, [W, \mathbf{Y}] \rangle.$$

Since the vertical metric  $g^{\mathcal{F}_2^{\perp}}$  is parallel with respect to Y, we have

$$\nabla_{\mathbf{Y}}^{\mathcal{F}_2^{\perp}} \boldsymbol{\nu} = [\mathbf{Y}, \boldsymbol{\nu}].$$

Then the argument used in [Zha17, Lemma 2.1] shows that [Y, v] is uniformly bounded. More precisely,

$$[Y,\nu] = \lim_{t\to 0} \frac{(\varphi_t^Y)_*\nu - \nu}{t}.$$

Let  $\alpha$  be the angle between  $\nu$  and  $(\phi_t^{\gamma})_*\nu$ , then  $|\nu - (\phi_t^{\gamma})_*\nu|^2 = 2 - 2\cos(\alpha)$ . Since the symmetric space has nonpositive curvature,

$$|\nu - (\phi_t^{\mathsf{Y}})_* \nu| \le \frac{d(f(\phi_t^{\mathsf{Y}}(\mathfrak{u})), f(\mathfrak{u}))}{\sqrt{d(g, f(\phi_t^{\mathsf{Y}}(\mathfrak{u})))d(g, f(\mathfrak{u}))}}$$

which is bounded by a uniform constant times t. This completes the proof.  $\Box$ 

We shall use the formula

(3.2) 
$$F(D) = \frac{2}{\pi} \int_0^\infty D(1 + \lambda^2 + D^2)^{-1} d\lambda$$

repetitively in the following calculation. Let  $e_1, e_2 \cdots, e_n$  be a local orthonormal frame of T $\mathcal{M}$  with respect to the decomposition (1.4) and the metric  $g^{T\mathcal{M}}$ . Let

(3.3) 
$$f_{i} = \begin{cases} \beta^{-1}e_{i} & \text{if } e_{i} \text{ is a section of } \mathcal{F}, \\ \epsilon e_{i} & \text{if } e_{i} \text{ is a section of } \mathcal{F}_{1}^{\perp}, \\ e_{i} & \text{if } e_{i} \text{ is a section of } \mathcal{F}_{2}^{\perp}, \end{cases}$$

then  $f_1, f_2 \cdots, f_n$  is a local orthonormal frame of  $T\mathcal{M}$  with respect to the metric  $g_{\beta,\varepsilon}^{T\mathcal{M}}$ . Then the sub-Dirac operator can be written as

(3.4) 
$$D_{S(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon} = \sum_{i=1}^{n} c_{\beta,\varepsilon}(f_{i}) \nabla_{f_{i}}^{S(\mathcal{F}\oplus\mathcal{F}_{1}^{\perp})\otimes\wedge^{*}\mathcal{F}_{2}^{\perp},\beta,\varepsilon},$$

where  $c_{\beta,\varepsilon}$  is the Clifford multiplication with respect to the metric  $g_{\beta,\varepsilon}^{T\mathcal{M}}$ .

We shall first verify the following Proposition.

**3.3 Proposition.** *The pair* (1.12) *is, indeed, a Kasparov*  $(C(M), \mathbb{C})$ *-module.* 

*Proof.* It suffices to check that

(3.5) 
$$\left[f, F(D_{S(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon} + T\widehat{c}(V))\right]$$

and

(3.6) 
$$\left(1 + \left(\mathsf{D}_{\mathsf{S}(\mathcal{F}_2^{\perp}),\beta,\varepsilon} + \mathsf{T}\widehat{c}(\mathsf{V})\right)^2\right)^{-1}$$

are compact operators for all  $f \in C(M)$ . Indeed,

(3.7) 
$$\left( \mathsf{D}_{\mathsf{S}(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon} + \mathsf{T}\widehat{\mathsf{c}}(\mathsf{V}) \right)^{2} = \mathsf{D}_{\mathsf{S}(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon}^{2} + \mathsf{T}^{2}\ell^{2} + \mathsf{T}\sum c_{\beta,\varepsilon}(\mathsf{f}_{i})\widehat{\mathsf{c}}(\nabla_{\mathsf{f}_{i}}^{\mathcal{F}_{2}^{\perp}}\mathsf{V}).$$

Since  $\nabla_{f_i}^{\mathcal{F}_2^{\perp}} V = f_i(\ell) \nu + \ell \nabla_{f_i}^{\mathcal{F}_2^{\perp}} \nu$ , according to Proposition 3.2, there is a constant  $\theta > 0$  which is independent of  $\beta, \epsilon \in (0, 1]$  such that

(3.8) 
$$T \sum c_{\beta,\epsilon}(f_i) \widehat{c}(\nabla_{f_i}^{\mathcal{F}_2^{\perp}} V) \leq T \theta(\ell + \beta^{-1}).$$

Therefore there is another positive constant C such that (3.7)  $\geq D^2_{S(\mathcal{F}_2^{\perp}),\beta,\varepsilon} + \ell - C$  which, according to [LS19, Prop B.1], implies that (3.6) is a compact operator.

As for the compactness of (3.5), we shall use the formula (3.2) for  $D = D_{S(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon} + T\hat{c}(V)$ . Notice that the compactness of (3.6) implies the compactness of

$$\left(\mathsf{D}_{\mathsf{S}(\mathcal{F}_{2}^{\perp}),\beta,\epsilon} + \mathsf{T}\widehat{\mathsf{c}}(\mathsf{V})\right) \left(1 + \left(\mathsf{D}_{\mathsf{S}(\mathcal{F}_{2}^{\perp}),\beta,\epsilon} + \mathsf{T}\widehat{\mathsf{c}}(\mathsf{V})\right)^{2}\right)^{-1}$$

According to the definition,  $f \in C(M)$  is taken as a function on  $\mathcal{M}$  which is constant along the fiber  $\mathcal{M} \to M$ , and the commutator

$$(3.9) \qquad [\mathsf{D}_{\mathsf{S}(\mathcal{F}_2^{\perp}),\beta,\varepsilon},\mathsf{f}] = \sum c_{\beta,\varepsilon}(\mathsf{f}_i)\mathsf{f}_i(\mathsf{f})$$

is bounded due to the compactness of M. The commutator of  $f \in C(M)$  with the integrand in (3.2) is then a compact operator whose norm is  $\mathcal{O}(1 + \lambda^2)^{-1}$ . This completes the proof.

**3.4 Remark.** In the above proof, the constant C may depends on the choice of  $\beta$  and  $\varepsilon$  while  $\theta$  is independent of these choices. In fact, from this section onward until the penultimate section, there are many constants appearing in various estimates,  $\theta$  is the only one that is independent of  $\beta$ ,  $\varepsilon$ .

We shall use the following Connes-Skandalis criterion for Kasparov product[Bla98, Definition 18.4.1].

**3.5 Proposition.** Let A, B, C be C\*-algebras,  $[E,F] \in KK(A,C)$  represents the KK-product of  $[E_1,F_1] \in KK(A,B)$  and  $[E_2,F_2] \in KK(B,C)$  if

- 1. F is a F<sub>2</sub>-connection;
- 2. for all  $a \in A$ ,  $a[F_1 \otimes 1, F]a^* \ge 0$  modulo compact operators.

**3.6 Proposition.** *The Kasparov product of* (1.10) *with* (1.11) *is given by* (1.12) *for all positive* T.

*Proof.* According to the definition of the sub-Dirac operator and the formula (3.4), we have

$$(3.10) \qquad (-1)^{\partial x} \mathsf{D}_{\mathsf{S}(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon} x \otimes y = \sum_{i=1}^{n} \nabla_{\mathsf{f}_{i}}^{\mathsf{S}(\mathcal{F}_{2}^{\perp})} x \otimes \mathsf{c}_{\beta,\varepsilon}(\mathsf{f}_{i}) y + x \otimes \mathsf{D}_{\beta,\varepsilon}^{\mathcal{M}} y,$$

for all homogeneous  $x \in C_c^{\infty}(\mathcal{M}, S(\mathcal{F}_2^{\perp}))$  and  $y \in C_c^{\infty}(\mathcal{M}, S^{T\mathcal{M}})$ . Let us first verify the connection condition and then the positivity condition.

•  $F\left(D_{S(\mathcal{F}_{2}^{\perp}),\beta,\epsilon} + T\widehat{c}(V)\right)$  is a  $F(D_{\beta,\epsilon}^{\mathcal{M}})$ -connection: let  $x \in C_{c}^{\infty}(\mathcal{M}, S(\mathcal{F}_{2}^{\perp}))$  be a homogeneous element, then the valuation of

(3.11) 
$$T_{x} \circ F(D_{\beta,\varepsilon}^{\mathcal{M}}) - (-1)^{\partial x} \cdot F\left(D_{S(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon} + T\widehat{c}(V)\right) \circ T_{x}$$

at  $y \in C_c^{\infty}(\mathcal{M}, S^{T\mathcal{M}})$  equals

$$(3.12) \quad \frac{2}{\pi} \int_0^\infty \left[ \mathbf{x} \otimes \mathbf{D}_{\beta,\varepsilon}^{\mathcal{M}} (1 + \lambda^2 + \mathbf{D}_{\beta,\varepsilon}^{\mathcal{M},2})^{-1} \mathbf{y} - (-1)^{\partial \mathbf{x}} \left( \mathbf{D}_{\mathbf{S}(\mathcal{F}_2^{\perp}),\beta,\varepsilon} + \mathbf{T} \widehat{\mathbf{c}}(\mathbf{V}) \right) \left( 1 + \lambda^2 + (\mathbf{D}_{\mathbf{S}(\mathcal{F}_2^{\perp}),\beta,\varepsilon} + \mathbf{T} \widehat{\mathbf{c}}(\mathbf{V}))^2 \right)^{-1} \mathbf{x} \otimes \mathbf{y} \right] d\lambda.$$

Let  $z = (1 + \lambda^2 + D^{\mathcal{M},2}_{\beta,\epsilon})^{-1}y$ , then the integrand in the above integral can be written as

$$\begin{split} \Big(1+\lambda^2+(D_{S(\mathcal{F}_2^{\perp}),\beta,\epsilon}+T\widehat{c}(V))^2\Big)^{-1}\cdot\\ & \Big[\left(1+\lambda^2+(D_{S(\mathcal{F}_2^{\perp}),\beta,\epsilon}+T\widehat{c}(V))^2\right)x\otimes D^{\mathcal{M}}_{\beta,\epsilon}z\\ & -(-1)^{\mathfrak{d}x}(D_{S(\mathcal{F}_2^{\perp}),\beta,\epsilon}+T\widehat{c}(V))x\otimes(1+\lambda^2+D^{\mathcal{M},2}_{\beta,\epsilon})z\Big]. \end{split}$$

According to the formula (3.10), the above integrand can be simplified as

$$\begin{split} &-(1+\lambda^2)\left(1+\lambda^2+(D_{S(\mathcal{F}_2^{\perp}),\beta,\epsilon}+T\widehat{c}(V))^2\right)^{-1}\cdot\\ &\qquad \left(\sum_{i=1}^n\nabla_{f_i}^{S(\mathcal{F}_2^{\perp})}x\otimes c_{\beta,\epsilon}(f_i)z+(-1)^{\partial x}T\widehat{c}(V)x\otimes z\right)\\ &+(D_{S(\mathcal{F}_2^{\perp}),\beta,\epsilon}+T\widehat{c}(V))\left(1+\lambda^2+(D_{S(\mathcal{F}_2^{\perp}),\beta,\epsilon}+T\widehat{c}(V))^2\right)^{-1}\cdot\\ &\qquad \left[T\widehat{c}(V)x\otimes D_{\beta,\epsilon}^{\mathcal{M}}z+(-1)^{\partial x}\sum_{i=1}^n\nabla_{f_i}^{S(\mathcal{F}_2^{\perp})}x\otimes c_{\beta,\epsilon}(f_i)D_{\beta,\epsilon}^{\mathcal{M}}z\right]. \end{split}$$

Since  $x \in C_c^{\infty}(\mathcal{M}, S(\mathcal{F}_2^{\perp}))$  is compactly supported, the action of  $\widehat{c}(V)$  is therefore bounded. The above integrand is a compact operator, acting on y, of norm  $\mathcal{O}(1 + \lambda^2)^{-1}$ , this verifies that (3.11) is a compact operator. For general  $x \in C_0(\mathcal{M}, S(\mathcal{F}_2^{\perp}))$  the corresponding operator (3.11) can be realized as norm-limit of those for  $x \in C_c^{\infty}(\mathcal{M}, S(\mathcal{F}_2^{\perp}))$ . This verifies the connection condition.

Positivity condition: it suffices to estimate the commutator

$$\left[\widehat{c}(\nu), F\left(\mathsf{D}_{\mathsf{S}(\mathcal{F}_2^{\perp}),\beta,\epsilon} + \mathsf{T}\widehat{c}(\mathsf{V})\right)\right]$$

which can be written as an integral

$$\frac{2}{\pi} \cdot \int_0^\infty \left[ \widehat{\mathbf{c}}(\mathbf{v}), \left( \mathsf{D}_{\mathsf{S}(\mathcal{F}_2^{\perp}),\beta,\varepsilon} + \mathsf{T}\widehat{\mathbf{c}}(\mathsf{V}) \right) \left( 1 + \lambda^2 + \left( \mathsf{D}_{\mathsf{S}(\mathcal{F}_2^{\perp}),\beta,\varepsilon} + \mathsf{T}\widehat{\mathbf{c}}(\mathsf{V}) \right)^2 \right)^{-1} \right] \mathrm{d}\lambda.$$

The integrand can be computed as

$$(3.13) \quad \left(1 + \lambda^{2} + (D_{S(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon} + T\widehat{c}(V))^{2}\right)^{-1} \cdot \left((1 + \lambda^{2}) \left[\widehat{c}(v), D_{S(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon}\right] + \left(D_{S(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon} + T\widehat{c}(V)\right) \left[D_{S(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon},\widehat{c}(v)\right] \left(D_{S(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon} + T\widehat{c}(V)\right)\right) \cdot \left(1 + \lambda^{2} + (D_{S(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon} + T\widehat{c}(V))^{2}\right)^{-1}$$

According to Proposition 3.2, the commutator  $\left[\widehat{c}(\nu), D_{S(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon}\right]$  is a bounded operator, the integrand (3.13) is a compact operator of order  $\mathcal{O}(\lambda^{-2})$ . This verifies the positivity condition.

## **4** Bismut-Lebeau analytic localization

In this section, we shall recycle the notations  $e_i$ ,  $f_i$  previously used in (3.3). Let  $e_1, e_2, \dots, e_n$  be a local orthonormal frame of  $T\mathcal{M}|_M \to M$  with respect to the decomposition (1.6) and the metric induced by  $g^{T\mathcal{M}}$ . Let

(4.1) 
$$f_{i} = \begin{cases} \beta^{-1}e_{i} & \text{if } e_{i} \text{ is a section of F,} \\ \epsilon e_{i} & \text{if } e_{i} \text{ is a section of TM/F,} \\ e_{i} & \text{if } e_{i} \text{ is a section of N,} \end{cases}$$

as defined in (3.3). Now,  $f_1, f_2, \dots, f_n$  is a local orthonormal frame of  $T\mathcal{M}|_M \to M$  with respect to the metric induced by  $g_{\beta,\varepsilon}^{T\mathcal{M}}$ . Let  $\tau e_i$ (resp.  $\tau f_i$ ) be the parallel translation of  $e_i$ (resp.  $f_i$ ) along the geodesics of the fibers of  $\mathcal{M} \to M$  with respect to the connection  $\nabla^{T\mathcal{M}}$ (resp. the Levi-Civita connection  $\nabla^{T\mathcal{M},\beta,\varepsilon}$ ).

Choose the local coordinate system (1.7), under which the tangent bundle of  $\mathcal{U}$  can be identified with the pullback bundle  $\pi^*T\mathcal{M}|_M$  along the projection  $\pi$ :  $\mathcal{U} \to M$ . Instead of the tangent bundle of  $\mathcal{U}$ , we shall use the pullback bundle for the local analysis in this section. Under this light, the sub-Dirac operator can be written as

$$D_{S(\mathcal{F}_{2}^{\perp}),\beta,\epsilon} = \sum_{i=1}^{n} c_{\beta,\epsilon}(f_{i}) \nabla_{\tau f_{i}}^{S(\mathcal{F} \oplus \mathcal{F}_{1}^{\perp}) \otimes \wedge^{*} \mathcal{F}_{2}^{\perp},\beta,\epsilon},$$

Let  $d\nu_{\mathcal{M}}(y, Z)$ ,  $d\nu_{\mathcal{M}}(y)$  and  $d\nu_{N_y}(Z)$  be the volume forms of manifolds  $\mathcal{M}, \mathcal{M}$ and the vector spaces  $N_y$  respectively. Assume that

$$d\nu_{\mathcal{M}}(\mathbf{y}, \mathsf{Z}) = \mathbf{k}(\mathbf{y}, \mathsf{Z}) d\nu_{\mathsf{M}}(\mathbf{y}) d\nu_{\mathsf{N}_{\mathsf{y}}}(\mathsf{Z}).$$

It is straightforward to see that k(y, 0) = 1 for all  $y \in M$  and the directional derivative of k with respect to  $e_i$  with  $i \le m$  at (y, 0) is equal to zero for all  $y \in M$ . In the following we shall need to calculate  $e_i(k)(y, 0)$  for  $m + 1 \le i \le n$ . Recall that connections  $\nabla^{T\mathcal{M}}$ ,  $\nabla^{\mathcal{F}\oplus\mathcal{F}_1^{\perp}}$ ,  $\nabla^{\mathcal{F}_2^{\perp}}$  and  $\nabla^{S(\mathcal{F}\oplus\mathcal{F}_1^{\perp})\otimes\wedge^*\mathcal{F}_2^{\perp}}$  are defined in (3.1). Let  ${}^0\nabla^{T\mathcal{M}} = \nabla^{\mathcal{F}\oplus\mathcal{F}_1^{\perp}} + \nabla^{\mathcal{F}_2^{\perp}}$ , let *A* be the 1-form given by  $A = \nabla^{T\mathcal{M}} - {}^0\nabla^{T\mathcal{M}}$  and  ${}^0\nabla^{S(\mathcal{F}\oplus\mathcal{F}_1^{\perp})\otimes\wedge^*\mathcal{F}_2^{\perp}}$  be the tensor product connection given by

$$\nabla^{\mathsf{S}(\mathcal{F}\oplus\mathcal{F}_1^{\perp})}\otimes 1+1\otimes \nabla^{\wedge^*\mathcal{F}_2^{\perp}}.$$

Then we have

$$\nabla^{S(\mathcal{F}\oplus\mathcal{F}_1^{\perp})\otimes\wedge^*\mathcal{F}_2^{\perp}} - {}^0\nabla^{S(\mathcal{F}\oplus\mathcal{F}_1^{\perp})\otimes\wedge^*\mathcal{F}_2^{\perp}} = \frac{1}{4}\sum_{i,j} \langle A(\cdot)e_i, e_j \rangle c(e_i)c(e_j).$$

We shall denote the last quantity by  $A^{S}(\cdot)$ .

**4.1 Proposition.** [BL91, Proposition 8.9] For  $m + 1 \le i \le n$ , we have  $e_i(k)(y, 0) = \sum_{j=1}^{m} \langle A(e_j)e_i, e_j \rangle$ .

*Proof.* Let J<sub>i</sub> be Jacobi fields of the form

(4.2) 
$$\frac{\partial}{\partial s}\Big|_{s=0}(y(s), tZ(s)).$$

More precisely, for  $m+1 \le i \le n$ ,  $J_i$  is defined by those (4.2) where y(s) is constant in M and Z(s) is a curve in N<sub>y</sub>; and for  $1 \le i \le m$ ,  $J_i$  is defined by those (4.2) where y(s) is a curve in M and Z(s) is constant. In another word,  $J_i$  are Jacobi fields J(t) with initial conditions

$$J(0) = 0, \frac{1}{\partial t}(0) \in \mathbb{N}$$

$$J(0) = \dot{y}(0), \frac{\partial J}{\partial t}(0) = \nabla_{\dot{y}(0)}^{\mathsf{T}\mathcal{M}} Z = A(\dot{y}(0))Z.$$

We shall, in addition, require J<sub>i</sub> to be a local orthonormal basis.

Write  $\tau e_i$  for the parallel translation of  $e_i$  along the geodesics  $t \mapsto (y, tZ)$  with respect to the connection  $\nabla^{TM}$ . According to the definition we have

$$\begin{split} k(y,Z) = & d\nu_{\mathcal{M}}(J_1,J_2,\cdots J_n) \\ = & det(\langle \tau e_i,J_j \rangle) \,. \end{split}$$

Its derivative at (y, 0) with respect to a certain normal vector Z is given by

(4.3) 
$$\sum_{i} \frac{\partial}{\partial Z} \langle \tau e_{i}, J_{i} \rangle = \sum_{i} \langle e_{i}, \nabla_{Z}^{T\mathcal{M}} J_{i} \rangle$$

It implies that  $\partial k/\partial Z(y, 0) = \sum_{i=1}^{m} \langle e_i, A(e_i)Z \rangle$ .

The tangent bundle of U or equivalently the tangent bundle of  $\mathcal{U}$  can be identified with the pullback bundle  $\pi^*(T\mathcal{M}|_M)$  along the projection  $\pi: N \to M$ . Under this identification, there is a diffeomorphism

$$\mathbb{S}(\mathcal{F}\oplus\mathcal{F}_1^{\perp})\otimes\wedge^*\mathcal{F}_2^{\perp}|_{U}\to\pi^*(\mathbb{S}^{\mathsf{TM}}\otimes\wedge^*\mathbb{N})|_{\mathcal{U}}.$$

In the following discussion, all local analysis near  $M \hookrightarrow \mathcal{M}$  will be performed on  $\pi^*(S^{TM} \otimes \wedge^* N) \to \mathcal{U}$ . We shall view  ${}^0\nabla^{S(\mathcal{F} \oplus \mathcal{F}_1^{\perp}) \otimes \wedge^* \mathcal{F}_2^{\perp}, \beta, \varepsilon}$  as a connection on  $\pi^*(S^{TM} \otimes \wedge^* N)|_{\mathcal{U}}$ .

From now on, we shall equip the Hilbert space  $L^2(\mathcal{U}, \pi^*(S^{TM} \otimes \wedge^*N))$  with the inner product

$$\langle f,g\rangle = \int_{\mathcal{U}} \langle f,g\rangle(y,Z) d\nu_{M}(y) d\nu_{N_{y}}(Z).$$

Let  $F_T$  be the operator on  $L^2(\mathcal{U}, \pi^*(S^{TM} \otimes \wedge^*N))$  that send a section s(y, Z) to  $F_T(s)(y, Z) = s(y, Z/\sqrt{T})$ .

As in [BL91], we shall write  $O(|Z|^2 \partial^N + |Z|\partial^H + |Z| + |Z|^p)$  for a family of first order differential operators with parameter T of the form

$$\sum_{i=1}^{m} \mathfrak{a}_{i}(T,y,Z)^{0} \nabla_{f_{i}^{H}}^{S(\mathcal{F} \oplus \mathcal{F}_{1}^{\perp}) \otimes \wedge^{*} \mathcal{F}_{2}^{\perp},\beta,\epsilon} + \sum_{i=m+1}^{n} \mathfrak{b}_{i}(T,y,Z)^{0} \nabla_{f_{i}}^{S(\mathcal{F} \oplus \mathcal{F}_{1}^{\perp}) \otimes \wedge^{*} \mathcal{F}_{2}^{\perp}} + c(T,y,Z),$$

such that there is a positive constant C with

 $a_{\mathfrak{i}}(T,y,Z) \leq C|Z|, \quad b_{\mathfrak{i}}(T,y,Z) \leq C|Z|^2 \quad \text{and} \quad c(T,y,Z) \leq C(|Z|+|Z|^p),$ 

for any  $T \ge 1$  and all (y, Z) such that  $(y, Z/\sqrt{T}) \in \mathcal{U}$ .

4.2 Proposition. [BL91, Theorem 8.18] Let

$$\mathsf{D}^\mathsf{H} = \sum_{i=1}^m c_{\beta,\epsilon}(f_i)^0 \nabla_{f_i^\mathsf{H}}^{\pi^*(\mathsf{S}^\mathsf{TM} \otimes \wedge^* \mathsf{N}),\beta,\epsilon}$$

and

$$D^{N} = \sum_{i=m+1}^{n} c(f_{i})^{0} \nabla_{f_{i}}^{\pi^{*}(S^{TM} \otimes \wedge^{*}N)},$$

then

(4.4) 
$$F_{T}k^{1/2} \left( D_{S(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon} + T\widehat{c}(V) \right) k^{-1/2}F_{T}^{-1} = D^{H} + \sqrt{T} \left( D^{N} + \widehat{c}(V) \right)$$

$$+rac{1}{\sqrt{T}}\mathcal{O}\left(|Z|^2\partial^N+|Z|\partial^H+|Z|
ight).$$

**4.3 Remark.** Of course, the operator  $D^H$  and the remainder terms

 $\mathcal{O}\left(|Z|^2 \vartheta^N + |Z| \vartheta^H + |Z|\right)$ 

depend on the parameters  $\beta$ ,  $\varepsilon$ . Since these parameters will not play significant role until the last section, we choose to omit  $\beta$ ,  $\varepsilon$  from the notation. The operator  $D^N$ , on the other hand, is independent of the parameters  $\beta$  and  $\varepsilon$ .

Proof. Indeed,

$$\begin{split} F_T k^{1/2} D_{S(\mathcal{F}_2^{\perp}),\beta,\epsilon} k^{-1/2} F_T^{-1} &= F_T \Big( -\frac{1}{2} k^{-1} c_{\beta,\epsilon}(f_i) \tau f_i(k) \\ &+ c_{\beta,\epsilon}(f_i)^0 \nabla^{S(\mathcal{F} \oplus \mathcal{F}_1^{\perp}) \otimes \wedge^* \mathcal{F}_2^{\perp},\beta,\epsilon}_{\tau f_i} + c_{\beta,\epsilon}(f_i) A^S(\tau f_i) \Big) F_T^{-1}. \end{split}$$

According to Proposition 4.1, the first term has limit

$$\frac{1}{2} \sum_{\substack{m+1 \leq i \leq n \\ 1 \leq j \leq m}} c_{\beta,\epsilon}(f_i) \langle A(f_j) f_i, f_j \rangle,$$

as  $T \to \infty.$  And the third term has limit, as  $T \to \infty$ 

$$\begin{split} &\frac{1}{4}\sum_{\substack{1\leq i\leq m\\1\leq j,k\leq n}}\langle A(f_i)f_j,f_k\rangle c_{\beta,\varepsilon}(f_i)c_{\beta,\varepsilon}(f_j)c_{\beta,\varepsilon}(f_k)\\ =&\frac{1}{2}\sum_{\substack{1\leq i,j\leq m\\m+1\leq k\leq n}}\langle A(f_i)f_j,f_k\rangle c_{\beta,\varepsilon}(f_i)c_{\beta,\varepsilon}(f_j)c_{\beta,\varepsilon}(f_k)\\ =&-\frac{1}{2}\sum_{\substack{1\leq i< m\\m+1\leq k\leq n}}\langle A(f_i)f_i,f_k\rangle c_{\beta,\varepsilon}(f_k), \end{split}$$

which cancel with the first term. The middle term is calculated as

$$\sum_{i=1}^{n} c_{\beta,\epsilon}(f_{i})^{0} \nabla_{p^{\mathsf{TM}}\tau f_{i}(y,Z/\sqrt{T})}^{S(\mathcal{F}\oplus\mathcal{F}_{1}^{\perp})\otimes\wedge^{*}\mathcal{F}_{2}^{\perp},\beta,\epsilon} + \sqrt{T} \sum_{i=1}^{n} c_{\beta,\epsilon}(f_{i})^{0} \nabla_{p^{\mathsf{N}}\tau f_{i}(y,Z/\sqrt{T})}^{S(\mathcal{F}\oplus\mathcal{F}_{1}^{\perp})\otimes\wedge^{*}\mathcal{F}_{2}^{\perp},\beta,\epsilon}.$$

It has limit

$$\sum_{i=1}^m c_{\beta,\epsilon}(f_i)^0 \nabla_{f_i^H}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + \sqrt{T} \sum_{i=m+1}^n c_{\beta,\epsilon}(f_i)^0 \nabla_{f_i}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon},$$

as  $T \to \infty$ . The remainder of the above estimates is  $\frac{1}{\sqrt{T}}\mathcal{O}(|Z|^2 \partial^N + |Z|\partial^H + |Z|)$ .

Since the conjugation with  $F_T^{-1}$  leaves the horizontal connection  ${}^{0}\nabla_{f_t^H}^{\pi^*(S^{TM}\otimes \wedge^*N),\beta,\epsilon}$  fixed and  $F_T^{-1}D^NF_T = \frac{1}{\sqrt{T}}D^N$ . Altogether, we have

$$k^{1/2} \left( \mathsf{D}_{\mathsf{S}(\mathcal{F}_2^{\perp}),\beta,\epsilon} + \mathsf{T}\widehat{c}(\mathsf{V}) \right) k^{-1/2} = \mathsf{D}^{\mathsf{H}} + \mathsf{D}^{\mathsf{N}} + \mathsf{T}\widehat{c}(\mathsf{V}) + \mathsf{R}_{\mathsf{T}},$$

where  $R_T = \mathcal{O}\left(|Z|^2 \vartheta^N + |Z| \vartheta^H + |Z|\right).$  It is easy to check that

$$(4.5) \quad \left(D^{N} + T\widehat{c}(V)\right)^{2} = \sum_{i=m+1}^{n} {}^{0}\nabla_{f_{i}}^{\pi^{*}(S^{TM} \otimes \wedge^{*}N),2} + T^{2}|Z|^{2} + T\sum_{i=m+1}^{n} c(f_{i})\widehat{c}(f_{i}).$$

The following result can be found in [Zha01, Section 4.5].

**4.4 Proposition.** The deformed Dirac operator  $D^N + T\hat{c}(V)$  has one dimensional kernel spanned by  $\exp(-T|Z|^2/2)$  and there is a constant C > 0 such that every nonzero eigenvalue is larger than or equal to CT.

Consider the following inclusion

(4.6) 
$$L^2(M, S^{TM}) \hookrightarrow L^2(\mathcal{U}, \pi^*(S^{TM} \otimes \wedge^* N)),$$

which is given by

$$s \mapsto \alpha_{\mathsf{T}} \exp(-\mathsf{T}|\mathsf{Z}|^2/2)\rho(\mathsf{Z})s,$$

where  $\rho(Z)$  is the function that only depends on |Z| and  $\rho(Z) = 0$  whenever Z falls outside of  $\mathcal{U}$  and  $\alpha_T$  is a constant to make the above inclusion an isometry. It is straightforward to see that  $\alpha_T = \mathcal{O}(T^{(n-m)/4})$  as  $T \to \infty$ .

**4.5 Remark.** Notice that our notation is slightly different from that of [BL91]. In particular, our  $\alpha_T$  is equivalent to their  $\alpha_T^{-1/2}$ . This is clear from [BL91, Definition 9.1].

Denote by  $p_T : L^2(\mathcal{U}, \pi^*(S^{TM} \otimes \wedge^* N)) \to L^2(\mathcal{U}, \pi^*(S^{TM} \otimes \wedge^* N))$  the projection onto the image of (4.6), then we have

(4.7) 
$$p_{T}(\varphi) = \alpha_{T}^{2} \exp(-T|Z|^{2}/2)\rho(Z) \int q\varphi(y, Z') \exp(-T|Z'|^{2}/2)\rho(Z') dZ'$$

for all  $\phi \in L^2(\mathcal{U}, \pi^*(S^{TM} \otimes \wedge^* N))$ , where  $q : S^{TM} \otimes \wedge^* N \to S^{TM}$  is the fiberwise projection.

**4.6 Lemma.** [BL91, Proposition 9.3] There is a constant C > 0, such that

$$\|p_{\mathsf{T}}|\mathsf{Z}|^{\gamma}s\|^{2}_{L^{2}(\mathcal{U})} \leq C\mathsf{T}^{-\gamma}\|s\|^{2}_{L^{2}(\mathcal{U})},$$

*for all*  $s \in L^2(\mathcal{U}, \pi^*(S^{\mathsf{TM}} \otimes \wedge^* \mathsf{N})).$ 

*Proof.* According to the formula of  $p_T$ , we have

$$|p_{T}|Z|^{\gamma}s||_{L^{2}}^{2} = ||\alpha_{T}\int qs(y,Z)|Z|^{\gamma}\exp(-T|Z|^{2}/2)\rho(Z)dZ||_{L^{2}}^{2}.$$

According to the Cauchy-Schwartz inequality, the integral on the right hand side is less than or equal to

$$\alpha_T^2 \int \|qs(y,Z)\|^2 dZ \cdot \int |Z|^{2\gamma} \exp(-T|Z|^2) \rho^2(Z) dZ \leq CT^{-\gamma} \|s\|_{L^2}^2.$$

This completes the proof.

The inclusion (4.6) can be further extended to

$$L^{2}(M, S^{TM}) \hookrightarrow L^{2}(\mathcal{U}, \pi^{*}(S^{TM} \otimes \wedge^{*}N)) \hookrightarrow L^{2}(\mathcal{M}, S(\mathcal{F} \oplus \mathcal{F}_{1}^{\perp}) \otimes \wedge^{*}\mathcal{F}_{2}^{\perp}),$$

where the second arrow sends a section f to  $fk^{-1/2}$  which is an isometric inclusion. Let  $\overline{p}_T : L^2(\mathcal{M}, S(\mathcal{F} \oplus \mathcal{F}_1^{\perp}) \otimes \wedge^* \mathcal{F}_2^{\perp}) \to L^2(\mathcal{M}, S(\mathcal{F} \oplus \mathcal{F}_1^{\perp}) \otimes \wedge^* \mathcal{F}_2^{\perp})$  be the projection onto the image of this extended inclusion, then

(4.8) 
$$\overline{p}_{T} = k^{-1/2} p_{T} k^{1/2}.$$

Following Bismut-Lebeau, we shall decompose the self-adjoint deformed Dirac operator

$$A_{T} = D_{S(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon} + T\widehat{c}(V),$$

according to the projection  $\overline{p}_T$ , into a two by two matrix  $\begin{bmatrix} A_{T,1} & A_{T,2} \\ A_{T,3} & A_{T,4} \end{bmatrix}$ , where

$$A_{T,1} = \overline{p}_T A_T \overline{p}_T, \quad A_{T,2} = \overline{p}_T A_T (1 - \overline{p}_T), \quad A_{T,3} = (1 - \overline{p}_T) A_T \overline{p}_T$$

and

$$A_{T,4} = (1 - \overline{p}_T)A_T(1 - \overline{p}_T).$$

Notice that  $A_{T,i}$  all depend on  $\beta$ ,  $\varepsilon$ . However the parameters will not play a significant role until the last section, we choose to omit them from the notation.

**4.7 Definition.** Let us write  $H_{T,4} \subset L^2(\mathcal{M}, S(\mathcal{F} \oplus \mathcal{F}_1^{\perp}) \otimes \wedge^* \mathcal{F}_2^{\perp})$  for the orthogonal complement of the image of  $\overline{p}_T$ .

Again, the space  $H_{T,4}$  depends on the parameters  $\beta$ ,  $\varepsilon$ , but we choose to omit them from the notation. Now we shall collect necessary estimates for each of the four entries  $A_{T,i}$  in the following three subsections.

#### 4.1 A<sub>T,1</sub>

The tangent bundle of M can be decomposed as  $TM = F \oplus TM/F$ . Recall that we have choose a distinguished Euclidean metric  $g^{TM/F}$  on TM/F and there is a metric  $g^F$  on F. Then TM can be given the metrics

$$\beta^2 g^F \oplus \frac{1}{\epsilon^2} g^{TM/F}$$

Let  $D_{\beta,\varepsilon}$  be the Dirac operator on M associate with the above metric.

**4.8 Proposition.** If we identify  $L^2(M, S^{TM})$  with the image of the projection  $p_T$ ,  $A_{T,1}$  can be taken as an operator on  $L^2(M, S^{TM})$ . Then there is a positive constant C > 0 such that the difference  $A_{T,1} - D_{\beta,\epsilon}$  is a first order differential operator whose coefficients all have sup-norm less than or equal to  $C/\sqrt{T}$  for all T > 1.

*Proof.* Let  $s \in L^2(M, S^{TM})$ , then

$$\begin{split} A_{T,1}s &= p_T k^{1/2} (D_{S(\mathcal{F}_2^{\perp}),\beta,\epsilon} + T\widehat{c}(V)) k^{-1/2} \alpha_T \exp(-T|Z|^2/2) \rho(Z) s \\ &= p_T (D^H + D^N + T\widehat{c}(V) + R_T) \alpha_T \exp(-T|Z|^2/2) \rho(Z) s, \end{split}$$

where  $R_T=\mathcal{O}\left(|Z|^2\partial^N+|Z|\partial^H+|Z|\right)$ . As  $exp(-T|Z|^2/2)$  is the kernel of  $D^N+T\widehat{c}(V),$  we have

$$\left(D^{N}+T\widehat{c}(V)\right)\alpha_{T}\exp(-T|Z|^{2}/2)\rho(Z)s = \alpha_{T}\exp(-T|Z|^{2}/2)c\left(\frac{\partial\rho}{\partial Z}(Z)\right)s.$$

The Clifford multiplication  $c\left(\frac{\partial \rho}{\partial Z}(Z)\right)$  can be split as sum of two operators one rise the order of  $\wedge^*N$  by one the other lower the order by one. Thus, its image under the projection  $p_T$  is zero. The same reasoning implies that the contribution from the term  $\hat{c}(\nabla_Z^2 V)$  is zero.

On the other hand, if (y(s), Z(s)) is a horizontal section of N over the curve  $y(s) : [0,1] \to Y$ , then  $\nabla^N_{\dot{y}(s)}Z(s) = 0$  which implies that |Z(s)| is constant for all  $s \in [0,1]$ . As a consequence, we have  $e_i^H \left( \exp(-T|Z|^2/2)\rho(Z) \right) = 0$  for any horizontal vector field  $e_i^H$ . Therefore,

$$p_T D^H \alpha_T \exp(-T|Z|^2/2)\rho(Z)s = \alpha_T \exp(-T|Z|^2/2)\rho(Z)D_{\beta,\epsilon}s,$$

which, under the light of the inclusion (4.6), can be taken as the element  $D_{\beta,\epsilon}s \in L^2(M, S^{TM})$ .

It remains to analyze the remainder term  $R_T$ . Since (4.9)

$$p_{\mathsf{T}}\alpha_{\mathsf{T}}|Z|^{2}\partial^{\mathsf{N}}\left(\exp(-\mathsf{T}|Z|^{2}/2)\rho(Z)s(y)\right) = p_{\mathsf{T}}\alpha_{\mathsf{T}}|Z|^{2}\partial^{\mathsf{N}}\left(\exp(-\mathsf{T}|Z|^{2}/2)\rho(Z)\right)s(y),$$

and the differential in the right hand side is of the form

$$\partial^{\mathsf{N}}\left(\exp(-\mathsf{T}|\mathsf{Z}|^{2}/2)\right)\rho(\mathsf{Z})+\exp(-\mathsf{T}|\mathsf{Z}|^{2}/2)\partial^{\mathsf{N}}\left(\rho(\mathsf{Z})\right).$$

According to the Lemma 4.6, (4.9)  $\leq CT^{-1/2} ||s||_{L^2(M,S^{TM})}$ . On the other hand,

$$p_T \alpha_T |Z| \partial^H \exp(-T|Z|^2/2) \rho(Z) s(y) = p_T \alpha_T |Z| \exp(-T|Z|^2/2) \rho(Z) \partial^H s(y)$$

whose norm is less than or equal to  $T^{-1/2}\alpha_T\|\partial^Hs\|_{L^2(M,S^{TM})}.$  Lemma 4.6 also implies that

$$\|p_{\mathsf{T}}\alpha_{\mathsf{T}}|Z|\exp(-\mathsf{T}|Z|^{2}/2)\rho(Z)s(y)\|_{L^{2}} \leq C\mathsf{T}^{-1/2}\|s\|_{L^{2}(M,S^{\mathsf{TM}})}.$$

This completes the proof.

**4.9 Proposition.** For any  $\beta$ ,  $\varepsilon$  there is a constant  $T_0 > 0$  such that  $[L^2(M, S^{TM}), F(A_{T,1})]$  is a Kasparov module whose class is the fundamental class given by the Dirac operator for all  $T \ge T_0$ .

*Proof.* For fixed  $\beta$ ,  $\varepsilon$ , according to the Proposition 4.8, the operator  $A_{T,1}$  is elliptic for sufficiently large T. Since M is compact,  $[L^2(M, S^{TM}), F(A_{T,1})]$  forms a Kasparov module. On the other hand, Proposition 4.8 also implies that  $F(A_{T,1})$  converges in the sense of strong operator topology to  $F(D_{\beta,\varepsilon})$ . This completes the proof.

#### **4.2** $A_{T,2}$ and $A_{T,3}$

**4.10 Proposition.**  $[D^H, p_T] = 0$ .

Proof. This is a straightforward calculation, on one hand,

$$D^{H}p_{T}\phi = \alpha_{T}^{2}\exp(-T|Z|^{2}/2)\rho(Z)\int D_{\beta,\epsilon}q\phi(y,Z')\exp(-T|Z'|^{2}/2)\rho(Z')dZ'.$$

On the other hand,

$$p_T D^H \phi = \alpha_T^2 \exp(-T|Z|^2/2)\rho(Z) \int q D^H \phi(y, Z') \exp(-T|Z'|^2/2)\rho(Z') dZ'.$$

The integral on the right hand side can be written as

(4.10) 
$$\sum_{i=1}^{m} \int q c_{\beta,\varepsilon}(f_i)^0 \nabla_{f_i^H}^{\pi^*(S^{TM} \otimes \wedge^* N),\beta,\varepsilon} \varphi(y,Z') \exp(-T|Z'|^2/2) \rho(Z') dZ'.$$

It is straightforward to see that the projection q commutes with Clifford multiplications  $c_{\beta,\epsilon}(f_i)$ , and

$$\begin{split} q^{0} \nabla_{f_{\iota}^{H}}^{\pi^{*}(S^{TM} \otimes \wedge^{*}N),\beta,\varepsilon} k \pi^{*} \phi_{1} \otimes \pi^{*} \phi_{2} \\ &= f_{\iota}^{H}(k) \phi_{2}^{[0]} \pi^{*} \phi_{1} + k \phi_{2}^{[0]} \pi^{*} \nabla_{f_{\iota}}^{S^{TM}} \phi_{1} + k f_{\iota}(\phi_{2}^{[0]}) \pi^{*} \phi_{1}, \end{split}$$

for all  $1 \leq i \leq m$ , k smooth function on  $\mathcal{U}$ ,  $\varphi_1$  smooth section of  $S^{TM} \to M$ and  $\varphi_2$  smooth section of  $\wedge^*N \to M$ . The first component  $f_i^H(k)\varphi_2^{[0]}\pi^*\varphi_1$  can be decomposed as

$$p^{N}f_{i}^{H}(k)\varphi_{2}^{[0]}\pi^{*}\varphi_{1}+f_{i}(k)\varphi_{2}^{[0]}\pi^{*}\varphi_{1}.$$

Since  $\exp(-T|Z'|^2/2)\rho(Z')$  is constant with respect to  $f_i^H$ , by an integration by part argument, the first summand in the above expression has no contribution to the integral (4.10). Therefore (4.10) equals

$$\int D_{\beta,\varepsilon} q \varphi(y, Z') \exp(-T|Z'|^2/2) \rho(Z') dZ'.$$

This completes the proof.

According to the discussion in Section 2, the Sobolev spaces  $H^{j}(K)$  for compact subset  $K \subset \mathcal{M}$  is well-defined and independent of the choice of metrics and connections. In the following, if  $s \in L^{2}(\mathcal{M}, S(\mathcal{F} \oplus \mathcal{F}_{1}^{\perp}) \otimes \wedge^{*} \mathcal{F}_{2}^{\perp})$  is compactly supported, we shall write  $||s||_{H^{1}}$  for its norm in the Sobolev space

$$\mathsf{H}^{1}\left(\mathsf{K},\mathsf{S}(\mathcal{F}\oplus\mathcal{F}_{1}^{\perp})\otimes\wedge^{*}\mathcal{F}_{2}^{\perp}\right)$$

for any compact subset  $K \subset \mathcal{M}$  that contains the support of s.

**4.11 Proposition.** For any compactly supported smooth function  $\chi$  on  $\mathcal{M}$  that equals 1 on  $\mathcal{U}$ , there is a constant C > 0 such that

$$\|A_{T,2}s\|_{L^{2}(\mathcal{M})} \leq C\left(\frac{1}{\sqrt{T}}\|\chi s\|_{H^{1}} + \|\chi s\|_{L^{2}(\mathcal{M})}\right),$$

for all  $s \in H_{T,4}$ , and

$$\|A_{T,3}s\|_{L^{2}(\mathcal{M})} \leq C\left(\frac{1}{\sqrt{T}}\|s\|_{H^{1}} + \|s\|_{L^{2}(\mathcal{M})}\right),$$

for all s belongs to the image of  $\overline{p}_{T}$ .

*Proof.* Since  $s \in H_{T,4}$ , according to (4.7) and (4.8), we have  $\chi s \in H_{T,4}$  and  $\overline{p}_T A_T s =$  $\overline{p}_T A_T \chi s$ . In the following analysis of  $A_{T,2}$  we shall always use  $\chi s$  instead of s. Let  $\overline{\chi s} = k^{1/2} \chi s$ , then

$$\|\overline{\chi s}\|_{L^2(\mathcal{U},\pi^*(S^{\intercal M}\otimes \wedge^*N))}=\|\chi s\|_{L^2(\mathcal{M},S(\mathcal{F}\oplus \mathcal{F}_1^{\bot})\otimes \wedge^*\mathcal{F}_2)}.$$

According to the definition of  $A_{T,2}$ , we have

$$\begin{split} A_{T,2}\chi s &= \overline{p}_T A_T \chi s \\ &= k^{-1/2} p_T \left( D^N + D^H + T \widehat{c}(V) + R_T \right) \overline{\chi s}, \end{split}$$

where

(4.11) 
$$p_{T}(D^{N} + T\widehat{c}(V))\overline{\chi s}$$
$$= \alpha_{T}^{2} \exp(-T|Z|^{2}/2)\rho(Z) \int q(D^{N} + T\widehat{c}(Z'))\overline{\chi s}(y, Z') \exp(-T|Z'|^{2}/2)\rho(Z')dZ'.$$

An integration by parts argument shows that

$$\begin{split} \int q(D^{N} + T\widehat{c}(Z'))\overline{\chi s}(y, Z') \exp(-T|Z'|^{2}/2)\rho(Z')dZ' \\ &= \int qc\left(\frac{\partial\rho}{\partial Z}(Z')\right)\exp(-T|Z'|^{2}/2)\overline{\chi s}(y, Z')dZ'. \end{split}$$

Therefore, there is a constant  $C_1 > 0$  such that

$$\begin{aligned} (4.12) \\ \|p_{T}(D^{N}+T\widehat{c}(V))\overline{\chi s}\|_{L^{2}(\mathcal{U})}^{2} &= \|\alpha_{T}\int qc\left(\frac{\partial\rho}{\partial Z}(Z)\right)\exp(-T|Z|^{2}/2)\overline{\chi s}(y,Z)dZ\|_{L^{2}(M)}^{2} \\ &\leq \alpha_{T}^{2}\int \left|\frac{\partial\rho}{\partial Z}(Z)\right|^{2}\exp(-T|Z|^{2})dZ\cdot\|\overline{\chi s}\|_{L^{2}(\mathcal{U})} \\ &\leq C_{1}T^{-1}\|\chi s\|_{L^{2}(\mathcal{M})}. \end{aligned}$$

According to Proposition 4.10, we have  $p_T D^H \overline{\chi s} = 0$ . According to Lemma 4.6, we have that there is a constant  $C_2 > 0$  such that

$$\begin{split} \|k^{-1/2} p_T R_T \overline{\chi s}\|_{L^2(\mathcal{M})} &\leq C_2 \Big( T^{-1} \|k^{-1/2} \vartheta^N k^{1/2} \chi s\|_{L^2(\mathcal{M})} \\ &+ T^{-1/2} \|k^{-1/2} \vartheta^H k^{1/2} \chi s\|_{L^2(\mathcal{M})} + T^{-1/2} \|\chi s\|_{L^2(\mathcal{M})} \Big). \end{split}$$

This completes the first part of the proof. If  $s \in L^2(\mathcal{U}, \pi^*(S^{TM} \otimes \wedge^*N))$  belongs to the image of  $\overline{p}_T$ , the action of  $A_{T,3}$  on s is given by

$$p_T^{\perp} \left( D^N + T \widehat{c}(V) \right) s + p_T^{\perp} R_T s$$

According to (4.12), for any  $s' \in L^2(\mathcal{U}, \pi^*(S^{\mathsf{TM}} \otimes \wedge^* N))$  we have

$$\left| \langle p_T \left( D^N + T \widehat{c}(V) \right) s, s' \rangle_{L^2(\mathcal{U})} \right| \leq C_1 T^{-1/2} \|s\|_{L^2(\mathcal{U})} \|s'\|_{L^2(\mathcal{U})}.$$

By taking the adjoint, the left hand side of the inequality is equal to

$$\langle s, (D^{N} + T\widehat{c}(V)) p_{T}s' \rangle_{L^{2}(\mathcal{U})}.$$

This shows that

$$\|\left(\mathsf{D}^{\mathsf{N}}+\mathsf{T}\widehat{\mathsf{c}}(\mathsf{V})\right)\mathsf{p}_{\mathsf{T}}\mathsf{s}\|_{\mathsf{L}^{2}(\mathcal{U})}\leq\mathsf{C}_{1}\mathsf{T}^{-1/2}\|\mathsf{s}\|_{\mathsf{L}^{2}(\mathcal{U})}.$$

Similarly, one has

$$\|\mathbf{R}_{\mathsf{T}}\mathbf{p}_{\mathsf{T}}\mathbf{s}\|_{L^{2}(\mathcal{U})} \leq C_{2}\mathsf{T}^{-1/2}\|\mathbf{s}\|_{\mathsf{H}^{1}}.$$

This completes the proof.

**4.12 Remark.** The operators  $A_{T,2}$ ,  $A_{T,3}$  can be decomposed into two parts

$$A_{T,2} = k^{-1/2} p_T \left( D^N + T \widehat{c}(V) \right) p_T^{\perp} k^{1/2} + k^{-1/2} p_T R_T p_T^{\perp} k^{1/2},$$

and

$$A_{T,3} = k^{-1/2} p_T^{\perp} \left( D^N + T \hat{c}(V) \right) p_T k^{1/2} + k^{-1/2} p_T^{\perp} R_T p_T k^{1/2}.$$

Their first components are bounded operators from  $L^2$  to  $L^2$ . Let

$$R = \begin{bmatrix} 0 & k^{-1/2} p_T R_T p_T^{\perp} k^{1/2} \\ k^{-1/2} p_T^{\perp} R_T p_T k^{1/2} & 0 \end{bmatrix}.$$

Then for any compact supported smooth function  $\chi \in C_c^{\infty}(\mathcal{M})$  that equals 1 on  $\mathcal{U}$ , there is a positive constant C such that

$$\| \mathbf{Rs} \|_{L^{2}(\mathcal{M})} \leq C T^{-1/2} \left( \| \chi s \|_{H^{1}} + \| \chi s \|_{L^{2}(\mathcal{M})} \right).$$

4.3 A<sub>T.4</sub>

**4.13 Lemma.** The horizontal Dirac operator  $D^H$  anti-commutes with the vertical Dirac operator  $D^N$  and the Clifford multiplication  $\hat{c}(V)$ .

Proof. On one hand,

$$\begin{split} D^{H}D^{N} &= \\ \sum_{\substack{1 \leq i \leq m \\ m+1 \leq j \leq n}} c_{\beta,\epsilon}(f_{i}) \left( c(\nabla_{f_{i}}^{N}f_{j}) + c(f_{j})^{0} \nabla_{f_{i}^{H}}^{\pi^{*}(S^{TM} \otimes \wedge^{*}N),\beta,\epsilon} \right) {}^{0} \nabla_{f_{j}}^{\pi^{*}(S^{TM} \otimes \wedge^{*}N),\beta,\epsilon} \end{split}$$

On the other hand,

$$D^N D^H = \sum_{\substack{1 \leq i \leq m \\ m+1 \leq j \leq n}} c(f_j) c_{\beta, \epsilon}(f_i)^0 \nabla_{f_j}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon_0} \nabla_{f_i^H}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon}$$

Their sum is equal to

$$\sum_{\substack{1 \leq i \leq m \\ m+1 \leq j \leq n}} c_{\beta,\epsilon}(f_i) c(\nabla_{f_i}^N f_j)^0 \nabla_{f_j}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_i) c(f_j)^0 \nabla_{[f_i^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_i) c(f_j)^0 \nabla_{[f_i^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_i) c(f_j)^0 \nabla_{[f_i^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_i) c(f_j)^0 \nabla_{[f_i^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_i) c(f_j)^0 \nabla_{[f_i^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_i) c(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_i) c(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_i) c(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_i) c(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_i) c(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_i) c(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{TM}} \otimes \wedge^* N), \beta, \epsilon} + c_{\beta,\epsilon}(f_j)^0 \nabla_{[f_j^H, f_j]}^{\pi^*(S^{\mathsf{T$$

Recall that the horizontal lifting of  $f_i$  is given by  $f_i^H(Z) = f_i - \nabla_{f_i}^N Z$ . As a consequence,  $[f_i^H, f_j] = [f_i - \sum_{m+1 \le k \le n} z^k \nabla_{f_i}^N f_k, f_j] = \nabla_{f_i}^N f_j$ . This shows that  $D^N D^H + D^H D^N = 0$ .

According to (1.9), V = Z and

$$D^{H}\widehat{c}(Z) = \sum_{i=1}^{m} c_{\beta,\epsilon}(f_{i})\widehat{c}(\nabla_{f_{i}^{H}}^{\pi^{*}N}Z) + \sum_{i=1}^{m} c_{\beta,\epsilon}(f_{i})\widehat{c}(Z)^{0}\nabla_{f_{i}^{H}}^{\pi^{*}(S^{\mathsf{TM}}\otimes\wedge^{*}N),\beta,\epsilon}.$$

As  ${}^{0}\nabla_{f_{i}^{H}}^{\pi^{*}N}Z = 0$  and  $\hat{c}$  anti-commute with c, we have  $D^{H}$  anti-commute with  $\hat{c}(\nabla_{Z}V)$ .

**4.14 Proposition.** 1. For any compactly supported smooth function  $\chi$  on M that is equal to 1 on U, there are constants C > 0 and  $T_0 > 0$  such that

$$\|A_{T,4}\chi s\|_{L^{2}(\mathcal{M})} \geq C\left(\|\chi s\|_{H^{1}} + T^{-1/2}\|\chi s\|_{L^{2}(\mathcal{M})}\right),$$

for all  $s \in H_{T,4}$  and for all  $T > T_0$ ;

2. The operator  $A_{T,4}$  is invertible for large enough T.

*Proof.* Let  $\delta$  be a sufficiently small positive constant to be determined. If s is supported within  $\delta$ -neighborhood of M inside  $\mathcal{M}$ , in this case, we take s as an element of  $L^2(\mathcal{U}, \pi^*(S^{\mathsf{TM}} \otimes \wedge^* N))$ . Then

(4.13) 
$$\|A_{\mathsf{T}}s\|_{L^{2}(\mathcal{U})}^{2} \geq \frac{1}{2} \|\left(\mathsf{D}^{\mathsf{H}} + \mathsf{D}^{\mathsf{N}} + \mathsf{T}\widehat{c}(\mathsf{V})\right)s\|_{L^{2}(\mathcal{U})}^{2} - \|\mathsf{R}_{\mathsf{T}}s\|_{L^{2}(\mathcal{U})}^{2}.$$

According to the above Lemma,  $(D^H+D^N+T\widehat{c}(V))^2=D^{H,2}+(D^N+T\widehat{c}(V))^2$  and

$$(4.14) \quad \| \left( D^{H} + D^{N} + T \widehat{c}(V) \right) s \|_{L^{2}(\mathcal{U})}^{2} = \| D^{H} s \|_{L^{2}(\mathcal{U})}^{2} + \| (D^{N} + T \widehat{c}(V)) s \|_{L^{2}(\mathcal{U})}^{2}.$$

Thanks to Proposition 4.4, there is a constant  $C_1 > 0$  such that

$$\|(D^{N} + T\hat{c}(V))s\|_{L^{2}(U)}^{2} \ge TC_{1}\|s\|_{L^{2}(U)}^{2}.$$

On the other hand, the square of  $D^N + T\hat{c}(V)$  is computed in (4.5), there is a constant  $C_2 > 0$  with

$$\|(D^{N} + T\hat{c}(V))s\|_{L^{2}(\mathcal{U})}^{2} \geq \langle D^{N,2}s,s\rangle_{L^{2}(\mathcal{U})} + T^{2}\||Z|s\|_{L^{2}(\mathcal{U})}^{2} - TC_{2}\|s\|_{L^{2}(\mathcal{U})}^{2}.$$

Altogether, one has

$$\begin{split} \|(D^{N}+T\widehat{c}(V))s\|_{L^{2}(\mathcal{U})}^{2} \geq \\ & \frac{1}{2}TC_{1}\|s\|_{L^{2}(\mathcal{U})}^{2} + \frac{\alpha}{2}\left(\langle D^{N,2}s,s\rangle_{L^{2}(\mathcal{U})} + T^{2}\||Z|s\|_{L^{2}(\mathcal{U})}^{2} - TC_{2}\|s\|_{L^{2}(\mathcal{U})}^{2}\right), \end{split}$$

for all  $\alpha \in (0, 1]$ . Notice that  $\alpha D^{N,2}/2 + D^{H,2}$  is an elliptic differential operator on  $\mathcal{M}$ , according to the elliptic regularity (2.2), there is a constant  $C_3 > 0$  such that

$$\langle \left(\frac{\alpha}{2}D^{N,2} + D^{H,2}\right)s,s \rangle_{L^{2}(\mathcal{U})} \geq C_{3} \|s\|_{H^{1}}^{2} - \|s\|_{L^{2}(\mathcal{U})}^{2}.$$

Overall, (4.14) can be estimated as

$$\geq C_3 \|s\|_{H^1}^2 + \left(\frac{1}{2}TC_1 - 1 - \frac{\alpha}{2}TC_2\right) \|s\|_{L^2(\mathcal{U})}^2 + \frac{\alpha}{2}T^2\||Z|s\|_{L^2(\mathcal{U})}^2.$$

The remaining part of (4.13) can be estimated as follows: there is a constant  $C_4 > 0$  that is independent of  $\alpha$  and  $\delta$  such that

$$\|R_{\mathsf{T}}s\|_{L^{2}(\mathcal{U})}^{2} \leq C_{4}\left(\delta^{2}\|s\|_{\mathsf{H}^{1}}^{2} + \delta^{2}\|s\|_{L^{2}(\mathcal{U})}^{2}\right).$$

Overall, we have

$$(4.15) ||A_{\mathsf{T}}s||^{2}_{\mathsf{L}^{2}(\mathcal{U})} \geq \left(\mathsf{C}_{3}-\mathsf{C}_{4}\delta^{2}\right)||s||^{2}_{\mathsf{H}^{1}} + \left(\frac{1}{2}\mathsf{T}\mathsf{C}_{1}-1-\frac{\alpha}{2}\mathsf{T}\mathsf{C}_{2}-\mathsf{C}_{4}\delta^{2}\right)||s||^{2}_{\mathsf{L}^{2}(\mathcal{U})}.$$

By choosing  $\alpha$  and  $\delta$  sufficiently small, there are constants C > 0, b > 0 such that

$$\|A_{\mathsf{T}}s\|_{L^{2}(\mathcal{U})}^{2} \ge C\left(\|s\|_{\mathsf{H}^{1}}^{2} + (\mathsf{T}-b)\|s\|_{L^{2}(\mathcal{U})}^{2}\right).$$

If s is supported away from  $\delta$ -neighborhood of  $M \hookrightarrow \mathcal{M}$ , then

$$\|A_{\mathsf{T}}s\|_{\mathsf{L}^{2}(\mathcal{M})}^{2} = \langle \left(\mathsf{D}_{\mathsf{S}(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon}^{2} + \mathsf{T}^{2}\ell^{2} + \mathsf{T}[\mathsf{D}_{\mathsf{S}(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon},\widehat{c}(\mathsf{V})]\right)s,s\rangle_{\mathsf{L}^{2}(\mathcal{M})}.$$

According to (3.8), for given smooth compactly supported function  $\chi$ , we have

$$\begin{split} \|A_{\mathsf{T}}(\chi s)\|_{\mathsf{L}^{2}(\mathcal{M})}^{2} &\geq \langle \mathsf{D}_{\mathsf{S}(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon}^{2}\chi s,\chi s\rangle_{\mathsf{L}^{2}(\mathcal{M})} + \\ & \mathsf{T}^{2}\|\ell\chi s\|_{\mathsf{L}^{2}(\mathcal{M})}^{2} - \mathsf{T}\theta\beta^{-1}\|\chi s\|_{\mathsf{L}^{2}(\mathcal{M})}^{2} - \mathsf{T}\theta\|\ell^{1/2}\chi s\|_{\mathsf{L}^{2}(\mathcal{M})}^{2}, \end{split}$$

here the constant  $\theta$  is the one used in (3.8). Again, as  $D_{S(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon}$  is an elliptic differential operator on  $\mathcal{M}$ , according to the elliptic regularity (2.2), there are constants  $C_5, C_6 > 0$  such that

$$\|A_{\mathsf{T}}(\chi s)\|_{L^{2}(\mathcal{M})}^{2} \geq C_{5}\|\chi s\|_{\mathsf{H}^{1}}^{2} + (\mathsf{T}^{2}\delta^{2} - \mathsf{T}C\beta^{-1} - 1 - \mathsf{T}C_{6})\|\chi s\|_{L^{2}(\mathcal{M})}^{2}.$$

One can choose  $T_1 > 0$  large enough such that

$$\|A_T\chi s\|_{L^2(\mathcal{M})}^2 \geq C_5\left(\|\chi s\|_{H^1}^2 + (T-b)\|\chi s\|_{L^2(\mathcal{M})}^2\right),$$

for all  $T > T_1$ . Together with (4.15), there is a constant  $C_7 > 0$  such that

$$\|A_T \chi s\|_{L^2(\mathcal{M})}^2 \ge C_7 \left( \|\chi s\|_{H^1}^2 + (T-b) \|\chi s\|_{L^2(\mathcal{M})}^2 \right),$$

for all  $s \in H_{T,4}$  and  $T > T_0 + T_1$ .

Now for  $s \in H_{T,4}$  we have  $A_{T,4}s = A_Ts - A_{T,2}s$ . The first part of the proposition is a consequence of Proposition 4.11.

The second part is a direct consequence of the first part.

#### **4.15 Proposition.** The resolvent $(\lambda - A_{T,4})^{-1}$ is compact for sufficiently large T.

*Proof.* Let  $\chi_n$  be a sequence of compactly supported smooth functions on  $\mathcal{M}$  that equal 1 on  $\mathcal{U}$  whose support sets  $\mathcal{M}_n$  are increasing and cover whole  $\mathcal{M}$ . We shall first prove that  $\chi_n(\lambda - A_{T,4})^{-1}$  is a compact operator for all  $n \in \mathbb{N}$  and then shows that  $\chi_n(\lambda - A_{T,4})^{-1}$  norm converges to  $(\lambda - A_{T,4})^{-1}$  as  $n \to \infty$ .

Let  $s \in H_{T,4},$  then according to the previous proposition there is a constant C > 0 such that

$$\begin{split} &\|\chi_{n}(\lambda - A_{T,4})^{-1}s\|_{H^{1}}\\ \leq & C\|A_{T,4}\chi_{n}(\lambda - A_{T,4})^{-1}s\|_{L^{2}}\\ \leq & C\|\chi_{n}A_{T,4}(\lambda - A_{T,4})^{-1}s\|_{L^{2}} + C\|[A_{T,4},\chi_{n}](\lambda - A_{T,4})^{-1}s\|_{L^{2}}. \end{split}$$

Since the commutator  $[A_T, \chi_n]$  is bounded and

$$[A_{T}, \chi_{n}] = \begin{bmatrix} [A_{T,1}, \chi_{n}] & [A_{T,2}, \chi_{n}] \\ [A_{T,3}, \chi_{n}] & [A_{T,4}, \chi_{n}] \end{bmatrix},$$

the lower right corner  $[A_{T,4}, \chi]$  is a bounded operator. According to the Rellich lemma (Proposition 2.1), the operator

$$\chi_n(\lambda-A_{T,4})^{-1}:H_{T,4}\to L^2(\mathcal{M},S(\mathcal{F}\oplus\mathcal{F}_1^{\perp})\otimes\wedge^*\mathcal{F}_2^{\perp})$$

is compact.

On the other hand,

$$A_{T}(\lambda - A_{T,4})^{-1}s = A_{T,2}(\lambda - A_{T,4})^{-1}s + A_{T,4}(\lambda - A_{T,4})^{-1}s$$

and according to Proposition 4.11, there is a constant

$$\|A_{T,2}(\lambda - A_{T,4})^{-1}s\|_{L^{2}(\mathcal{M})} \leq C\left(\frac{1}{\sqrt{T}}\|\chi_{n}(\lambda - A_{T,4})^{-1}s\|_{H^{1}} + \|\chi_{n}(\lambda - A_{T,4})^{-1}s\|_{L^{2}}\right).$$

The estimate in the previous paragraph ensures that  $A_{T,2}(\lambda - A_{T,4})^{-1}$  is a bounded operator. As a consequence, the operator  $\chi_n(\lambda - A_{T,4})^{-1}$  can be decomposed as

$$H_{T,4} \xrightarrow{(\lambda - A_{T,4})^{-1}} dom(A_T) \xrightarrow{\chi_n} L^2(\mathcal{M}, S(\mathcal{F} \oplus \mathcal{F}_1^{\perp}) \otimes \wedge^* \mathcal{F}_2^{\perp}).$$

It suffices to show that dom( $A_T$ )  $\xrightarrow{\chi_n} L^2$  norm-converges to the identity operator. Indeed, there is a sequence of constants  $\{C_n\}_{n\in\mathbb{N}}$  that goes to positive infinity and

$$(\mathsf{D}_{\mathsf{S}(\mathcal{F}_{2}^{\perp}),\boldsymbol{\beta},\varepsilon} + \mathsf{T}\widehat{\mathsf{c}}(\mathsf{V}))^{2} \ge C_{\mathfrak{n}}$$

outside  $\mathcal{M}_n$ . If u is a unit vector in the domain of  $D_{S(\mathcal{F}_2^{\perp}),\beta,\epsilon} + T\hat{c}(V)$ , that is u satisfies

$$\|\boldsymbol{u}\|_{L^2}^2 + \|\left(\boldsymbol{D}_{\boldsymbol{S}(\mathcal{F}_2^{\perp}),\boldsymbol{\beta},\boldsymbol{\epsilon}} + \boldsymbol{T}\widehat{\boldsymbol{c}}(\boldsymbol{V})\right)\boldsymbol{u}\|_{L^2}^2 = 1.$$

Then

$$1 \ge \int \langle \left( \mathsf{D}_{\mathsf{S}(\mathcal{F}_2^{\perp}),\beta,\epsilon} + \mathsf{T}\widehat{c}(\mathsf{V}) \right)^2 \mathfrak{u}(\mathfrak{m}), \mathfrak{u}(\mathfrak{m}) \rangle d\mathfrak{m}$$

As a consequence

$$\langle \mathfrak{u}(\mathfrak{m}),\mathfrak{u}(\mathfrak{m})\rangle d\mathfrak{m} \leq 1/C_{\mathfrak{n}}.$$

In another word,  $\|(1-\chi_n)u\|_{L^2}^2 \leq 1/C_n$ . This completes the proof.

## 5 Equivalent Kasparov module

Let  $A'_{\mathsf{T}} = \begin{bmatrix} A_{\mathsf{T},1} & 0\\ 0 & A_{\mathsf{T},4} \end{bmatrix}$ .

**5.1 Proposition.** The pair  $[L^2(\mathcal{M}, S(\mathcal{F} \oplus \mathcal{F}_1^{\perp}) \otimes \wedge^* \mathcal{F}_2^{\perp}), A'_T(1 + A'_T^{-2})^{-1/2}]$  is a Kasparov  $(C(\mathcal{M}), \mathbb{C})$ -module.

*Proof.* Since  $A'_T$  is self-adjoint, it is enough to show that for every  $f \in C(M)$ ,  $[A'_T(1 + A'_T{}^2)^{-1/2}, f]$  and  $f(1 + A'_T{}^2)^{-1}$  are compact. According to the previous discussion,  $A'_T$  has compact resolvent for large enough T, the compactness of  $f(1 + A'_T{}^2)^{-1}$  follows from here.

As for the compactness of  $[A'_{T}(1+A'_{T}^{2})^{-1/2}, f]$ , it is enough to show the boundedness of  $[f, A_{T,4}]$ . Since  $f \in C(M)$  taken as a function on  $\mathcal{M}$  is constant along the fiber of  $\mathcal{M} \to M$ , it commutes with the projection  $\overline{p}_{T}$ . As a consequence

$$[\mathbf{f}, \mathbf{A}_{\mathsf{T}, \mathsf{4}}] = \overline{\mathbf{p}}_{\mathsf{T}}^{\perp} [\mathbf{f}, \mathbf{D}_{\mathsf{S}(\mathcal{F}_{\mathsf{T}}^{\perp}), \beta, \varepsilon}] \overline{\mathbf{p}}_{\mathsf{T}}^{\perp},$$

which is, according to (3.9), clearly bounded. This completes the proof.

We shall use he following result of Connes and Skandalis to simplify the Kasparov modules.

**5.2 Proposition.** Let (E, F) and (E', F') be Kasparov (A, B)-modules, if  $\phi(a)[F, F']\phi(a^*) \ge 0$  mod compact operators then these two Kasparov modules define the same KK element. In particular, if  $||F - F'|| \le 1$  mod compact operators then (E, F) and (E', F') define the same KK element.

**5.3 Proposition.** When T is sufficiently large we have

$$\|A_{\mathsf{T}}(1+A_{\mathsf{T}}^2)^{-1/2} - A_{\mathsf{T}}'(1+A_{\mathsf{T}}'^2)^{-1/2}\| \le 1$$

mod compact operators.

Proof. Indeed,

$$\begin{split} &A_{T}(1+A_{T}^{2})^{-1/2} - A_{T}'(1+A_{T}'^{2})^{-1/2} \\ &= \int (1+\lambda^{2}+A_{T}^{2})^{-1} \left( (1+\lambda^{2})(A_{T}-A_{T}') + A_{T}(A_{T}'-A_{T})A_{T}' \right) (1+\lambda^{2}+A_{T}'^{2})^{-1} d\lambda. \end{split}$$

As we are estimating the norm mod compact operators, the bounded part of the difference  $A_T - A'_T$  make no contribution to the norm and, according to the Remark 4.12, one may replace  $A_T - A'_T$  by  $R = \begin{bmatrix} 0 & p_T R_T p_T^{\perp} \\ p_T^{\perp} R_T p_T & 0 \end{bmatrix}$ . Let  $\{x_i\}$  and  $\{y_j\}$  be two sets of orthonormal bases of  $L^2(\mathcal{M}, S(\mathcal{F} \oplus \mathcal{F}_1^{\perp}) \otimes \wedge^* \mathcal{F}_2^{\perp})$  given by the eigenvectors of  $A'_T$  and  $A_T$  respectively, the corresponding eigenvalues are denoted by  $a_i \in \mathbb{R}$  and  $b_j \in \mathbb{R}$  respectively. Then

(5.1) 
$$\left\langle \left( A_{T}(1+A_{T}^{2})^{-1/2} - A_{T}'(1+A_{T}'^{2})^{-1/2} \right) x_{i}, y_{j} \right\rangle \\ = \left\langle Rx_{i}, y_{j} \right\rangle \int (1+\lambda^{2}+b_{j}^{2})^{-1}(1+\lambda^{2}-a_{i}b_{j})(1+\lambda^{2}+a_{i}^{2})^{-1} d\lambda$$

mod compact operators. According to the Remark 4.12, for fixed  $\chi \in C_c^{\infty}(\mathcal{M})$  that equals 1 on  $\mathcal{U}$ , there is a constant C > 0 such that

$$|\langle Rx_i, y_i \rangle| \le ||Rx_i||_{L^2} \le CT^{-1/2} (||\chi x_i||_{H^1} + 1).$$

According to Proposition 4.8 and Proposition 4.14, there is a constant  $C_1$  that is independent of T such that

$$\begin{split} \|\chi x_{i}\|_{H^{1}} &= \|\overline{p}_{T} x_{i}\|_{H^{1}} + \|\chi \overline{p}_{T}^{\perp} x_{i}\|_{H^{1}} \\ &\leq C_{1} \left( \|A_{T,1} \overline{p}_{T} x_{i}\|_{L^{2}} + \|A_{T,4} \chi \overline{p}_{T}^{\perp} x_{i}\|_{L^{2}} \right) \\ &\leq C_{1} \left( \|A_{T,1} p_{T} x_{i}\|_{L^{2}} + \|A_{T,4} p_{T}^{\perp} x_{i}\|_{L^{2}} + \|[A_{T,4}, \chi] p_{T}^{\perp} x_{i}\|_{L^{2}} \right). \end{split}$$

Notice that the sum of the first two terms in the third line equals  $||A'_T x_i||_{L^2} = a_i$  and the last term in the third line is less than or equal to some constant that independent of T. As a consequence, the absolute value of (5.1) is controlled by

$$C(a_{i}+1)\int (1+\lambda^{2}+b_{j}^{2})^{-1}(1+\lambda^{2}-a_{i}b_{j})(1+\lambda^{2}+a_{i}^{2})^{-1}d\lambda \cdot T^{-1/2}.$$

The constant before  $T^{-1/2}$  is uniformly bounded with respect to real numbers  $a_i, b_j$ . As  $T \to \infty$ , one can make this value less than 1. This completes the proof.

Therefore, the Kasparov module (1.12) determines the same class as the one in Proposition 5.1 if T is sufficiently large. The module can be decomposed as

$$[L^2(M, S^{TM}), F(D)] \oplus [H_{T,4}, F(A_{T,4})].$$

The Kasparov product of (1.2) with the first summand in the above module is the Rosenberg index of M and the product with the second summand is given by

$$\left[\mathsf{H}_{\mathsf{T},4}\otimes_{\mathsf{C}(\mathsf{M})}\mathsf{C}(\mathsf{M},\mathsf{E}),\mathsf{F}(\mathsf{A}_{\mathsf{T},4})\otimes\mathsf{1}\right].$$

Since  $A_{T,4}$  is invertible for large T, one can choose F to be

$$\mathsf{F} = \begin{cases} 1 & x > 0, \\ -1 & x \le 0. \end{cases}$$

Notice that the function F by itself is not smooth, however, the functional calculus  $F(A_{T,4})$  only depends on the restriction of F to the spectrum of  $A_{T,4}$  where the function F is indeed smooth. The above module is then degenerate.

**5.4 Proposition.** *The Kasparov product of* (1.2)*,* (1.10) *and* (1.11) *is the Rosenberg index of* M.

### 6 Invertibility

For  $\beta, \epsilon \in (0, 1]$ , we have the following Lichnerowicz formula

$$\left(\mathsf{D}_{\mathsf{S}(\mathcal{F}_2^{\perp}),\beta,\epsilon} + \mathsf{T}\widehat{c}(\mathsf{V})\right)^2 = \mathsf{D}^2_{\mathsf{S}(\mathcal{F}_2^{\perp}),\beta,\epsilon} + \mathsf{T}^2\ell^2 + \mathsf{T}\sum_{i=1}^n c_{\beta,\epsilon}(f_i)\widehat{c}(\nabla_{f_i}^{\mathcal{F}_2^{\perp}}\mathsf{V}).$$

Since  $\nabla_{f_i}^{\mathcal{F}_{2}^{\perp}} V = f_i(\ell)v + \ell \nabla_{f_i}^{\mathcal{F}_{2}^{\perp}} v$ , according to Proposition 3.2, the norm of  $\sum_{i=1}^{n} c_{\beta,\epsilon}(f_i) \widehat{c}(\nabla_{f_i}^{\mathcal{F}_{2}^{\perp}} V)$  is less than or equal to  $\theta(\ell + \beta^{-1})$  for some constant  $\theta > 0$ . As pointed out in Remark 3.4, this constant  $\theta$  is independent of  $\beta, \epsilon$  and T. Let  $T = 1/\alpha\beta$ , choose  $\alpha$  and  $R_0$  such that

(6.1) 
$$R_0 > 8a\theta \ge 1 \text{ and } k^F/4 > \theta/a,$$

where k<sup>F</sup> is the leafwise scalar curvature.

Then for all  $\beta, \epsilon \in (0, 1]$  we have

$$\mathsf{T}^{2}\ell^{2} + \mathsf{T}\sum_{i=1}^{n} c_{\beta,\varepsilon}(f_{i})\widehat{c}(\nabla_{f_{i}}^{\mathcal{F}_{2}^{\perp}}\mathsf{V}) \geq \frac{\ell^{2}}{a^{2}\beta^{2}} - \frac{\theta\ell}{a\beta} - \frac{\theta}{a\beta^{2}}$$

According to the assumption (6.1), the above quantity is positive outside  $\mathcal{M}_{R_0}$  and hence the kernel of  $D_{S(\mathcal{F}_2^{\perp}),\beta,\epsilon} + T\hat{c}(V)$  is supported within  $\mathcal{M}_{R_0}$ .

On the other hand, in  $\mathcal{M}_{R_0}$ 

$$\mathsf{D}^{2}_{\mathsf{S}(\mathcal{F}_{2}^{\perp}),\beta,\varepsilon} = -\Delta^{\beta,\varepsilon} + \frac{k^{\mathcal{F}}}{4\beta^{2}} + \mathsf{O}_{\mathsf{R}_{0}}(\frac{1}{\beta} + \frac{\varepsilon^{2}}{\beta^{2}}).$$

The square of  $D_{S(\mathcal{F}_{2}^{\perp}),\beta,\epsilon} + T\widehat{c}(V)$  is larger than

$$\frac{k^{\mathsf{F}}}{4\beta^2} - \frac{\theta}{\alpha\beta^2} - \frac{\theta\ell}{\alpha\beta} + O_{\mathsf{R}_0}(\frac{1}{\beta} + \frac{\varepsilon^2}{\beta^2}),$$

where the first two terms together, according to the assumption (6.1) is a positive number over  $\beta^2$ . By making  $\beta$  and  $\varepsilon$  sufficiently small, the operator  $D_{S(\mathcal{F}_2^{\perp}),\beta,\varepsilon} + T\widehat{c}(V)$  is positive on  $\mathcal{M}_{R_0}$ .

As a consequence, the Kasparov product of (1.2) with (1.12), which is given by

 $\left[L^2(\mathcal{M},S^{T\mathcal{M}}\otimes\wedge\mathcal{F}_2^{\perp})\otimes_{C(M)}C(M,E),F(A_T)\otimes 1\right],$ 

is the zero element in  $KK(\mathbb{C}, \mathbb{C}^*\pi_1)$ . Together with Proposition 5.4 we have proved Theorem 1.6.

# Acknowledgment

The authors would like to thank Professor Weiping Zhang for suggesting this problem to us and for many enlightening discussions.
