

ON THE CAUSAL EFFICACY OF QUALIA: PHILOSOPHICAL ZOMBIES ARE FINE-TUNED, AND IMPLICATIONS FOR THE QUANTUM MEASUREMENT THEORY

ADAM BROWNSTEIN*

February 11, 2025

ABSTRACT. We suggest that qualia have a causally efficacious role in quantum mechanics; an occurrence which explains how information about qualia can enter the physical environment. This is compatible with the unitary time-evolution of the quantum state if qualia are understood as effecting the beables of the de Broglie-Bohm interpretation or wavefunction collapse process rather than at the wavefunction level. We furthermore suggest that not all quantum states are consistent with qualia. If this is the case, the standard wavefunction collapse postulates of the Copenhagen interpretation will fail to select only those states which are consistent with qualia, and the Born-rule must be modified if wavefunction collapse is to generate the correct dynamical histories across time. This new model which includes qualia clearly demonstrates how non-linear and self-referential phenomena can occur, despite the linear, deterministic time-evolution of the wavefunction. We reject the notion that physical matter operates independently of qualia, and find that the main evidence for epiphenomenalism i.e. the causal closure of the underlying physical time-evolution, has failed to take into consideration fine-tuning of the microcausal degrees of freedom. We propose that the philosophical zombie argument is fine-tuned in the initial conditions, thus making philosophical zombies statistically unlikely if the fine-tuning is removed. We furthermore suggest the presence of fine-tuning can be used as a test for consciousness in the general case. This explains why some classical processes such as computer circuits may never be conscious; because they lack the capacity for fine-tuning when the dynamics is reversed.

1. INTRODUCTION

A very puzzling phenomenon in physics is that our experiences of qualia, i.e. our internal conscious experiences, appear to have an effect upon the world. Why this is strange is that the physical matter has no knowledge of qualia, as it is purely a non-physical phenomena. As the hard problem of consciousness [1] has shown, the experience of ‘what it’s like to be a brain-state’ is distinct from the collection of neurons which make up the physical brain. This naturally leads to the question of how information about qualia enters the physical environment. If this information doesn’t come from qualia, where does it come from? Is it just a convincing illusion? Or perhaps is there a causal role for qualia?

It is often assumed that consciousness is a physical phenomena, possibly arising out of self-referential information processing, irreducible quantum states, or emergent behaviour in the brain. However, these purely physical explanations cannot address the hard problem, because the experience of ‘what it’s like to be physical matter’ cannot be explained in terms of physical matter alone. The experience of ‘what it’s like to be’¹ is an additional property over and above any material or mathematical explanation.

It is also often assumed that physics is a closed, causal dynamical theory. Therefore, any role for consciousness must only be an epiphenominal one, i.e. an apparent causality. However, this proves to be false when examined more closely. While quantum mechanics is a causal theory, it specifies an open-ended probabilistic dynamics, and therefore is not closed. Therefore, the question of whether the theory is deterministic is subtle. It is deterministic in some interpretations, such as the deterministic version of the de Broglie-Bohm interpretation. However, there is an equivalent stochastic de Broglie-Bohm interpretation, and the Copenhagen interpretation likewise describes probabilistic outcomes. These probabilistic or stochastic interpretations indicate that the dynamics is not closed.

Taking both facts together, there is an explanatory gap as to how information about qualia can enter the physical environment; and there remains a possibility that qualia play a causal role by guiding the open-ended probabilistic outcome of quantum mechanics. We contend that epiphenomenalism fails to explain how this information about qualia arrives into the physical environment, and therefore the explanatory gap points directly toward a defect in the quantum measurement theory as defined by the Born-rule.

To make our philosophical position clear, we fully endorse the existence of the hard problem of consciousness. For example, it is possible to describe the quantum mechanics of particles or fields, but the physics alone cannot explain why ‘what it’s like’ to be these particles or fields is a specific conscious experience rather than simply a

¹For instance Nagel’s “What is it like to be a bat?” [2]

non-conscious state of matter. Therefore, the challenge is to find a suitable role for conscious experience in the existing scientific paradigm.

Taking conscious experiences (qualia) as real, there are only a few available options. Either qualia are causally efficacious, or they are an epiphenomenon. An epiphenomenon means that they have no causal role, but are like a projected image of the underlying reality. If they are an epiphenomenon, then they are arbitrary, and hypothetically can be altered in thought experiments.

These thought experiments which remove or alter qualia pose a significant challenge to the epiphenomenalist viewpoint. Indeed, everything we do as conscious human beings is driven by qualia; sight, sound, touch, internal sensation, cognition, and emotion are all forms of qualia. If you remove or alter the qualia, it is not clear whether the physical system can still operate in the same way as it did previously. Our contention is that epiphenomenalism only works as an apparent explanation retroactively, looking backward at the previous time-evolution of a system. To explain the forward time-evolution however, it appears that epiphenomenalism fails, and qualia must play a causal role. The distinction between these two cases is the presence or absence of fine-tuning in the microcausal degrees of freedom.

In our view, the evidence that information about qualia is transmitted into the physical world indicates that a causal role for qualia is a logical necessity. The challenge then is to identify a suitable mechanism which is compatible with the deterministic time-evolution of the physical system. This is not as insurmountable as is commonly believed. For instance, suppose that qualia influenced the wavefunction collapse process in the Copenhagen interpretation. Would this not explain both the apparent causal impact of qualia, whilst retaining the deterministic dynamics of the underlying physics as given by the Schrödinger equation? This is the type of model which seems to be necessary to explain how experiences of qualia can impact the real world i.e. in a top-down causal fashion, whilst simultaneously allowing room for a reductionist physical description.

Alternatively, the problem can be understood in terms of the de Broglie-Bohm interpretation. In this case, the qualia are related to the beables of the de Broglie-Bohm interpretation, but they have an additional causal role. This role may either be i) to have a causal influence upon themselves or ii) to have a causal influence upon the beables. These two possibilities are compatible with quantum mechanics, because the dynamics of the wavefunction remains unaffected.

It is of course indicative that the Born-rule might not be strictly correct, as it fails to take into account the causal role of qualia. If the Born-rule were entirely correct, no causal role for qualia would be required, and epiphenomenalism would adequately explain consciousness. However as will be discussed, the evidence is suggestive of a causal role for qualia, thus indicating the insufficiency of the Born-rule.

Once the causal role for qualia is established, many things become clear. Firstly, it makes sense of how information about qualia can enter the physical environment. Secondly, it makes sense of how non-linear and self-referential effects can occur within quantum mechanics, without resorting to an explanation in terms of classical mechanics as is commonly done. Thirdly, it makes sense of whether macroscopic classical circuits can be conscious. These points will be discussed in detail in the following sections of this paper, along with other strong pieces of evidence.

In regards to the question of consciousness in classical circuits, we come to some intriguing conclusions. We find that fine-tuning is a hallmark of consciousness, otherwise the system cannot support causally efficacious qualia. The lack of fine-tuning in macroscopic classical circuits may indicate that classical computers as presently envisaged are not capable of consciousness, even if they have functional input-output behaviours that simulate consciousness. This goes beyond the Turing test, because we are able to provide a test for consciousness in terms of the physical dynamical picture, rather than a system's functional behaviour.

The causal role for qualia reopens the question of how organic life (both conscious and non-conscious) is able to maintain states of high information content and low entropy. It is likely that consciousness didn't emerge spontaneously, and biological systems may have evolved to utilise a basic causal mechanism present in nature which is responsible for the effect. Therefore, non-sentient matter may also be utilising the same causal mechanism to support life.

2. MODELS OF CAUSATION

2.1. Model 1: Epiphenomenalism. One might easily believe that consciousness is all a neurobiological process. For instance the brain of an individual can perceive colour by operating a sequence of neuron firings. However, what is concerning is that the neurons themselves never see the colour, it is held in the mind's-eye of the individual. While there is a one-to-one correlation between the pattern of neurons firing and the perceptions of qualia, there is no explanation of how the information from qualia feeds back down into the neural network.

Either there is a direct top-down causal role that the perceptions of qualia play, or alternatively, we only have the illusion of a causal role being played. The idea that qualia are an epiphenomenon takes the position of believing

this is only an apparent causality. It is as if the physical world is projected into our mind's-eye where a convincing drama plays out.

This is somewhat compatible with the de Broglie-Bohm interpretation, but not entirely. If qualia are assigned in a one-to-one fashion with the beables of the de Broglie-Bohm interpretation, then on the surface there is no issue. The conscious experience will continue to play the epiphenomenal drama, while the underlying quantum wavefunction and beables do all the real work of specifying the dynamics.

However, it doesn't explain how the physical matter is able to react in a way compatible with our experiences of qualia, despite never having access to the knowledge derived from those experiences. For instance, in the de Broglie-Bohm interpretation, the beables (e.g. particle configuration) have no knowledge of the particular colours, sounds, emotions or thoughts experienced. How then does information about these things enter the physical environment? The fact this information about qualia can be encoded physically, for instance as written or verbal reports, indicates that the information contained in qualia feeds back into the physical world.

This information about qualia is not part of the wavefunction. Nor is it part of the wavefunction collapse postulates of the Copenhagen interpretation. Therefore, the standard physical description never contains the information in theory. In practice however, this information is commonplace. Everywhere around us is the information we have received from qualia and imparted into the physical world. Either the information about qualia is just a projection of the information already contained within the physical matter, or more likely, there is a correlating mechanism forcing physical matter to conform with our perceptions of qualia.

There may be no other way to get this information into the physical world other than to allow qualia to have a causal role. The question then is how this can be the case. Viewing the problem using the reductionist picture in terms of neurons, cells, atoms and subatomic particles; everything appears causal and deterministic. Quantum field theory too has shown that nature is deterministic down to the very basic structure of matter. But does a deterministic physical description really mean everything has been determined?

Perhaps a crucial piece of the puzzle has slipped the attention of the reductionist paradigm; physical phenomena can both have a causal reductionist explanation as a necessary condition, with an additional causal influence acting as a sufficient condition. In other words, the dynamics can be deterministic but open-ended, allowing for an additional causal influence to close the dynamics. It is only when determinism is both necessary and sufficient that the dynamics can be considered deterministic and closed, with no room for additional causal influences to be injected into the dynamical picture.

Therefore, there is room in the causal reductionist paradigm for a mechanism that filters information about qualia back down into the physical time-evolution. This explains both why it appears as if everything is determined by the initial conditions when looking retroactively at the time-evolution, and simultaneously where the mysterious information about qualia arises from when looking at the forward time-evolution.

2.2. Model 2: Interactionism. As stated above, instead of qualia being an epiphenomenon, it is possible they affect the deterministic dynamics in a causal manner. We suggest that in the interactionist model, qualia act upon the de Broglie-Bohm particle configuration to bring about this causal influence. We do not suggest that qualia affect the wavefunction, which has a closed deterministic dynamics that is fully specified.

Top-down causation is indeed compatible with bottom-up reductionist determinism. The de Broglie-Bohm interpretation itself provides a specific example of this type of dual causation. It is worth reviewing the mechanism of the de Broglie-Bohm interpretation further to provide insight into how a similar strategy can be applied to qualia.

How the de Broglie-Bohm interpretation works is that the wavefunction provides the bottom-up reductionist causal picture. But it defines a multiplicity of possible states i.e. the branches of the wavefunction. Then, a de Broglie-Bohm particle configuration is able to occupy a specific branch of the wavefunction. The guidance equation or quantum potential plays a top-down causal role as it directs the particle configuration down a specific wavefunction branch. Therefore, the de Broglie-Bohm interpretation adds a different kind of causality on top of the wavefunction, yet the whole system remains deterministic. And now qualia are hypothesized in this paper to add a different kind of causality on top of the de Broglie-Bohm interpretation, and similarly we can argue the system remains deterministic.

The question to ask is "Does the wavefunction know about qualia?". For instance, if a person writes about the blueness of the ocean, was this part of the wavefunction dynamics? Or did the wavefunction just set up the preconditions for a possible world in which this occurs. Indeed, because the wavefunction encodes every possible world, it sets up the conditions for every possible occurrence to happen, including this one.

Clearly, the wavefunction does not know about qualia. The wavefunction is perfectly described in the reductionist paradigm by the unitary time-evolution. So then what then does guide this person to contemplate the blue colour? Perhaps it was the Copenhagen interpretation, which selects a branch of the wavefunction at random, in which the person contemplates a particular colour like a card from a deck. Or more likely perhaps, there were subtle influences

arising from qualia, which guided their branch of the wavefunction in a particular direction compatible with their experiences of qualia.

The de Broglie-Bohm interpretation tells a story similar to these subtle influences about qualia. It says that the probability distribution can influence the particle configuration down a particular branch of the wavefunction. However, are these the only influences? Perhaps other qualia, such as perceptions of image, sound, cognition and emotion also exert an influence. If there are influences from the qualia, they can help guide the particle configuration down a different branch, and in doing so link the experience of qualia into a coherent story. This is precisely what the de Broglie-Bohm interpretation has achieved for telling a coherent dynamical story about the probability outcomes, but a similar coherent story needs to be told about the other remaining qualia, noting that the Born-rule probabilities can themselves be considered a type of qualia.

When framed in this light, we have an explanation of how someone can perceive colour and write information about it on a page. Observing the colour caused neurons in their brain to fire in a particular pattern. This created an experience of qualia in their mind's-eye. The qualia then caused their de Broglie-Bohm particle configuration to alter its course down a different branch of the wavefunction; which in turn caused their neurons to alter their pattern of firing from the default course; which subsequently caused the person to write about what they had perceived.

When viewed only from the perspective of the classical-level description of neurons firing, it all seems deterministic with no room for a causal explanation. Therefore, one might be misled to believe the reductive physical explanation has told the whole story. What is missing is the fact that the top-down causal influence is acting like a switching mechanism, rather than as an overt influence upon the motion. The switching mechanism enables the particle configuration to choose between the different branches of the wavefunction, much like a train which is able to switch between different branching tracks. Each branch of the wavefunction describes a deterministic time-evolution, therefore looking backward at a particular trajectory it appears deterministic. However, additional causal influences are able to affect which branch is chosen when it comes to the bifurcation points.

2.2.1. *Quantum interpretations.* Alternatively to using the de Broglie-Bohm interpretation, one could equivalently say that the qualia affect the wavefunction collapse process of the Copenhagen interpretation. We recognize that every statement made within the de Broglie-Bohm interpretation has an equivalent statement in the Copenhagen interpretation, and within most quantum interpretations compatible with the Born-rule probabilities. Therefore, the arguments proposed within this paper are relevant to other quantum interpretations. We use the de Broglie-Bohm interpretation as it provides a particularly clear formulation of the problem. However, it is possible to translate these statements to other interpretations as required.

2.3. **Model 3: Parallelism.** An alternative model is that qualia only have a causal impact upon themselves. In this approach, the qualia may receive information from the beables of the de Broglie-Bohm interpretation, but have a separate dynamics of their own. This is similar to how the beables have a separate motion, but are related to the wavefunction by a novel mechanism. The information received would act as correlating mechanism which forces to qualia and beables to match, just as the guidance equation is a correlating mechanism forcing the beables and wavefunction to match.

It is interesting to note that if one examines the logic of the de Broglie-Bohm interpretation closely, it resembles the model of psychophysical parallelism as proposed by Leibniz. The de Broglie guidance equations ensure that the beables match the wavefunction, thus creating the 'pre-established harmony'. What was not recognised in the model was that a wavefunction could set up multiple possible branches, so it is not necessary to correlate the dynamics between the material and non-material worlds in advance. In other words, the de Broglie-Bohm interpretation has the 'harmony' component (i.e. correlating mechanism), but not the 'pre-established' component of the statement. Setting up many branches of the wavefunction serves as a replacement for correlating the two time-evolutions in advance.

2.3.1. *Many Born-rule worlds.* The general model of parallelism can also be extended to qualia. Instead of a single de Broglie-Bohm particle configuration or single set of beables, it is possible there may be an ensemble of them. This would create a multiplicity of possible Born-rule worlds, similar to how the wavefunction sets up multiple branches (which contain both Born-rule and non Born-rule worlds).

In this scenario, instead of directly affecting the motion of the beables, the qualia then can have an independent motion. The qualia will be able to select which set of beables they choose to replicate, and there is possibility for subtle causal influences to guide their path.

This is an intriguing proposal, because it views the de Broglie-Bohm interpretation on the same level as a Many-Worlds interpretation for the Born-rule worlds defined by the beables. In fact, it may be philosophically preferable, because of the conceptual barrier between the material and non-material worlds.

To explain the conceptual barrier further, one might expect that all causal influences which affect the material world can be described mathematically, since the material world itself has a mathematical description. And furthermore, one might expect that all things which can be described mathematically can be represented as part of the material world. Therefore, it is difficult to understand how a causal influence can cross from the non-material world of qualia to the material world, without itself being represented mathematically and becoming part of the material world.

If the de Broglie-Bohm particle configuration is material, then it is difficult to understand how a causal influence from qualia can cross the divide. However, by having an ensemble of de Broglie-Bohm beables, qualia only need to influence their own dynamics by selecting a specific set of beables to replicate; and therefore the causal influence does not need to cross the divide. However, we do note that a) perhaps our understanding of this conceptual divide is limited, and causal influences possibly can cross b) perhaps beables are on the non-material side of the divide, which would obviate the issue or c) perhaps the causal influence is a non-physical effect, similar to the anthropic principle, which is an effect of post-selection on the state.

3. ARGUMENTS AGAINST EPIPHENOMENALISM

There are two main strategies for explaining conscious experience. Firstly, it may play a causal role. Secondly, it may be an epiphenomenon. In the previous section, we primarily focused on how consciousness can play a causal role. In this section, we will focus on why it cannot be an epiphenomenon.

3.1. Arbitrariness. A first class of argument against epiphenomenalism is that if consciousness has no link to the underlying physical dynamics, then it is arbitrary. Why not then change the colour red to green, or make even more dramatic changes? No changes to the perceptions of qualia will affect the time-evolution of the physical matter.

3.1.1. *Rebuttal.* To rebut the arbitrariness argument, it might be said that the qualia are uniquely determined by the physical matter, like a film projection which is uniquely determined by the roll of film which is played. This is a valid argument to make, and therefore it is not useful to consider thought experiments where the qualia are partially altered e.g. inverting red to green. These changes may simply give nonsensical accounts of qualia, which violate the uniqueness assumption of the mapping from the physical states to qualia.

This is to say it is possible to take an “all or nothing” approach to qualia i.e. states either have the full set of qualia or none. By taking an “all or nothing” approach, the only remaining arbitrariness arguments against epiphenomenalism come from philosophical zombie thought experiments. In these thought experiments, the hypothetical alteration made to the qualia is to make it completely absent. We argue that the philosophical zombie thought experiments display information about qualia entering the physical picture from an unknown source, which is identified to be the fine-tuned microcausal degrees of freedom.

3.2. Corollary: Brain-region replacement. There is one notable exception to the “all or nothing” approach. While it is not possible to arbitrarily change the qualia assuming the one-to-one mapping, it is possible to change the physical picture of the brain without affecting the functional input-output relations of its operation, and this change in the physical picture may in turn change the qualia. This leads to thought experiments where individual brain regions are replaced by non-conscious circuits, for instance replacing a particular brain region with a computer chip.

Assuming the classical computer circuit is not capable of consciousness, making this change might produce a partial removal of some qualia, while preserving the overall physical operation of the brain. If these thought experiments produce logical contradictions, they provide evidence against epiphenomenalism. The fate of epiphenomenalism would be forced to hang in the balance of whether classical computer circuits are conscious or non-conscious, or at least whether they can be integrated along with biological neurons in the formation of qualia.

3.2.1. *Replacing the color-perception region.* Consider a thought experiment where the brain region responsible for colour perception is replaced by a classical computer circuit, thus potentially removing the qualia of colour perception. Suppose this person is shown a green and a red object, and asked to choose which one is green. They may have a sense of the green object, because the functional information processing capabilities of their brain are unchanged. However, because colour perception is no longer part of their qualia, they will not be able to directly observe the colours in their mind’s eye. Therefore, the sense of the green colour will only be subconscious. This seems to be contradictory, because a basic property of consciousness is that it is known when our decisions are based upon a conscious awareness of our qualia, and when they are based upon gut feeling or subconscious reasons outside of our awareness.

It is as if our conscious experience sets up a barrier between self i.e. that which is within conscious awareness, and non-self i.e. that which is outside of conscious awareness. For instance, when a decision is made based upon

gut feeling, we may have a sense that it is the right decision, but we do not know precisely why we have that sense. If instead a decision is made based upon our qualia, we know precisely why we have made the decision, and have an understanding of the causal factors and qualia involved.

3.2.2. Implications. If one assumes that qualia play no causal role, it is difficult to explain why the two scenarios (of having a completely biological brain or a brain partially replaced by a computer chip) are different. A brain region which has been replaced with the artificial circuit should theoretically behave exactly the same as an organic brain in terms of functional operation. Yet it is evident that the removal of the qualia of colour from the individual by making this replacement will result in different behaviours. Their perception of causal completeness of their qualia will be altered. Therefore, we conclude that these thought experiments produce a contradiction. It is evidence that qualia do indeed play a causal role.

3.3. Information causality. The second major class of argument against epiphenomenalism is that if epiphenomenalism is true, information about qualia enters the physical world with no known causal mechanism. Our perceptions of qualia alter our actions, which causes the information to be encoded from our experiences into the arrangement of physical matter. If one denies this causal role, then how does this information enter the physical environment? There are several peculiar aspects to this:

- (1) Physical reality always seems to be biased toward encoding the truth value of statements about qualia. Yet the physical matter has never observed the qualia directly. For instance, a person could be asked a binary question about their qualia such as “Is your experience of qualia continuous?”, to which they answer either yes or no. When answering this question, somehow the word yes rather than no always becomes part of the physical world. Yet there is no explanation for how this information enters the physical world, or what this information pertains to, if epiphenomenalism is true.
- (2) This information about qualia has to come from somewhere. However, if one looks at the quantum description of the time-evolution, it is not present there. The initial quantum state does not contain it. The time-evolution operators do not contain it. Therefore, the time-evolved wavefunction does not contain it. The information is not a part of the paradigm of quantum mechanics at all.
- (3) We suggest that when this information is not properly accounted for (e.g. by abstracting qualia away from the physical dynamical picture) it gets shifted into the fine-tuned microcausal degrees of freedom, and will be present in the initial state of the de Broglie-Bohm particle configuration for example. The presence of fine-tuning is theoretically very undesirable, as it means the initial state a) contains future information and b) lacks robustness to specification.

3.3.1. Rebuttal. A rebuttal can potentially be made that if qualia are an epiphenomenon this may only be an apparent causality. From this viewpoint, the answer to the question of where the information came from is that there is a one-to-one correlation between qualia and the physical brain states. Therefore, the information is already present in the physical world, just hidden in a different form. This argument falls apart however, because it is not clear how the physical environment ever contained the information in the first place. It is just another way to suggest that the microcausal degrees of freedom of the initial state contain hidden information, and therefore it is indicative of fine-tuning.

There is a second way to explain the situation using epiphenomenalism. Perhaps the information is never part of the physical environment, only apparently so. For instance, perhaps the information is always contained within our mind’s perception and interpretation of the physical environment, and is never actually transmitted to the physical environment. For instance, if the word yes is written rather than no, this only has a semantic meaning in our mind; so it is more a matter of how the conscious mind assigns meaning to physical states of the environment.

This is a somewhat convincing account, yet it is not correct to state that the physical matter never contains the information. Certainly, the physical world itself is not able to interpret the information carried by the arrangement of physical matter, but the physical matter acts as the storage medium and carrier of the information. This is similar to how words written on a page store information, yet the words are only meaningful when read by a person. Requiring a person to read the words doesn’t detract from the fact that the information is contained in the arrangement of words on the page.

Furthermore, the information about qualia imparted into the physical world can i) be shared and transmitted to other individuals ii) be copied and replicated and iii) has meaning in relation to other information derived from qualia. This is all suggestive that the information actually is imparted into the physical environment.

3.4. Corollary: Spontaneous emergence of statements about qualia.

3.4.1. *“Zombie island” thought experiment.* Imagine a tribe located on a remote island, where each member of this tribe are all philosophical zombies from birth. Nobody on the island has ever experienced qualia. This tribe develops language, culture, writing and philosophical reasoning independently from the rest of the world. Because the physical description is identical to the case where they do have qualia in the epiphenomenalist paradigm, they supposedly start describing experiences of qualia. They communicate properties about their qualia; for instance that it is continuous in nature, that it has a single locus of identity instead of several, that they can see colours and feel sensations. Yet they have never actually experienced this qualia.

Where did all of this information about qualia arise from? It didn’t come from within them, because they were born without qualia. It didn’t come from past culture, because nobody in their prior culture ever experienced it. And it didn’t come from the environment either, for their environment only contained non-sentient matter.

Apparently, the information must have come from the pattern of neurons firing in their brain. However, it would be extremely unlikely for a closed system such as this to develop descriptions for what qualia is like. This indicates that something is wrong in the physical description of this system. Knowledge about qualia cannot spontaneously arise in the physical world without some causal reason or origin of the information.

3.4.2. *Free and counterfactual philosophical zombie arguments.* In actuality, there is no evidence that this is how the dynamical time-evolution will play out. If the physical system undergoes free time-evolution in isolation from conscious experience, it is not clear that the philosophical zombies would be able to function similar to real human beings.

The typical story told about philosophical zombies is based upon the assumption of having a reference system, and removing the non-physical aspects of qualia from the picture. However, this procedure is questionable, as the end result is a set of physical particle trajectories that have co-evolved with qualia, thus the trajectories have been post-selected on the existence of qualia. To give an accurate account of the physical situation in the forward-directed sense of the time-evolution, it is necessary to distinguish between free time-evolution and counterfactual time-evolution that has been post-selected.

- (1) Counterfactual (post-selected) time-evolution: This is the traditional philosophical zombie argument. Take a dynamical system (reference system) and split the material description from the non-material component. Only look at the material description in isolation.
 - (a) It is possible to do this, because the de Broglie-Bohm beables ensure that a deterministic material description of the time-evolution exists when looking at the counterfactual, post-selected state. Therefore, philosophical zombies are possible. Because philosophical zombies are possible, it demonstrates that consciousness is an additional fact which needs to be supposed in addition to the material description. Thus the hard problem of consciousness is established.
 - (b) However, the deterministic state has potentially been influenced by qualia, as it has co-evolved with the presence of qualia. The initial state (e.g. the initial positions of de Broglie-Bohm particles) has been influenced by specifying the final state (post-selection) owing to the deterministic paradigm which provides a one-to-one mapping between initial and final states. Choosing the final state also determines the initial state due to the deterministic time-evolution, which results in fine-tuning.
 - (c) To understand this further, imagine the dynamics as a branching process. Looking backward, all of the emanating branches converge to a root branch, which causes the dynamics to appear causally closed and fully determined. Looking forward however, the diverging branches make the dynamics open-ended and requiring further specification. It is easy to miss the fact that there was a causal influence guiding the choice of branches along the way if one only looks at the backward time-evolution. All of the information about the causal influences from qualia will become shunted into the microcausal degrees of freedom e.g. fine-tuning of the initial state of de Broglie-Bohm particles, if the final state is post-selected and qualia are ignored.
- (2) Free time-evolution: This is the “zombie island” thought experiment. The physical description is described separately from the non-physical phenomena from the outset. There is no reference system, and the dynamical time-evolution takes place completely de novo. Furthermore, ideally no conscious entities are present in the initial state. Therefore, the system has never encountered qualia at any stage.
 - (a) This system will fail to develop spontaneous emergence of information about qualia. This is because the microcausal degrees of freedom have not been fine-tuned by a counterfactual, post-selection procedure.

3.4.3. *Analogy to the anthropic principle.* A useful analogy can be made to the anthropic principle. When one looks backward (counterfactually) at the previous time-evolution of the cosmos and life on Earth, it can be seen that upon each step of the process, there was a deterministic causal explanation for it. However, the events which unfolded were extremely unlikely to occur statistically. The anthropic principle has been a guiding force which has

enabled the statistical likelihoods to be overcome. The anthropic principle plays a quasi-causal role, forcing the statistics to generate a particular outcome, due to post-selection of the final state.

A similar situation is occurring in the philosophical zombie thought experiments. Philosophical zombies that can make statements about qualia are extremely unlikely to occur naturally in the free-time evolution. However, the statistical likelihoods can be overcome due to the influence of qualia along the way. Ignoring the guiding influence of qualia and unknowingly imposing post-selection upon the final state results in seemingly paradoxical phenomenon such as the apparent spontaneous emergence of statements about consciousness.

3.4.4. *Generality.* Just as the hard problem of consciousness says that there can be no purely physical explanation of consciousness experience, we believe that the spontaneous emergence of statements about consciousness (e.g. in the “zombie island” thought experiments) indicates that there can be no purely epiphenomenal explanation. Therefore:

- (1) Physicalism is false (as demonstrated by the hard problem of consciousness).
- (2) Epiphenomenalism is false (as demonstrated by spontaneous emergence of statements of consciousness).
- (3) Therefore, a causal role for qualia is true.

3.5. **Self-referential information.** A third class of argument against epiphenomenalism is that conscious beings observe and act upon self-referential information. Yet the underlying dynamics provided by the quantum formalism is deterministic and linear, so has no capacity for self-referential behaviour.

3.5.1. *Looking in the mirror.* If the wavefunction undergoes linear time evolution, how can a person see themselves in the mirror and then act upon their observation? What it implies is that there is a feedback mechanism between qualia and physical matter. How it works is roughly as follows:

- (1) Receiving step: Photons are emitted from the surface of the human body and reflected in the mirror. The eye then receives the photons, which causes a signal to be transmitted to the brain. This causes the wavefunction to branch into many different brain-states. The de Broglie-Bohm particle configuration occupies a specific branch of the wavefunction corresponding to a particular brain-state (i.e. pattern of neurons firing). The specific configuration of de Broglie-Bohm particles also causes a specific qualia of sight to occur in the mind’s-eye of the individual, due to a mapping between the de Broglie-Bohm particle configuration and the qualia experienced.
- (2) Emitting step: The qualia will then cause the de Broglie-Bohm particle configuration to change branch. The fact the de Broglie-Bohm particle configuration has changed branch will cause the neurons to fire in a different pattern than would have otherwise occurred, causing motion of the individual’s body that is reactive to the visual stimulus.

In this new explanation, there is a recursive feedback loop between the physical environment and the qualia, enabled by its impact upon the particle configuration. This enables self-referential information to impact the dynamics of physical matter.

3.5.2. *Copenhagen interpretation.* The above picture is in stark contrast to the story told by the Copenhagen interpretation. The explanation provided by the Copenhagen interpretation is approximately as follows: “The wavefunction continually collapses into a classical state. Although the quantum time-evolution is entirely linear, because there is a classical explanation of the brain process in terms of neurons firing, it is explainable as a self-referential loop in terms of this classical-level description. Quantum mechanics is a linear theory, but wavefunction collapse makes it non-linear.” This story is problematic because a) it evokes classical mechanics to explain the situation. Essentially, it is an admission that quantum mechanics fails to explain the phenomena, and b) it assumes the classical-level description is deterministic (which is correct) and not fine-tuned (which is incorrect).

To see what is wrong with the explanation, the Schrödinger time-evolution can be continued for longer in a no-collapse interpretation of the wavefunction. This will not introduce self-referential, non-linear information into the physical description because the Schrödinger time-evolution is linear. After a long period of time evolution, the quantum state will contain decoherent branches representing the variety of possible classical worlds. Although the states of the world in which this non-linear behavior occurs are present in the wavefunction, they will have small wavefunction amplitudes and are unlikely to be selected by the Born-rule.

3.5.3. *Number of cycles.* Note that the greater number self-referential cycles that occur, the greater the deviation between the probability for the real state observed and the probability amplitudes described by the quantum formalism. This is why self-referential loops pose such a problem for quantum mechanics. If there is one cycle of emission of photons and reflection from the mirror, the wavefunction amplitudes may deviate a small amount. However, if one stands in front of the mirror for some time, a constant stream of photons are emitted and reflect

from the mirror. The self-referential loop will have many cycles, which will cause a large deviation of the real probabilities from the quantum amplitudes.

Typically, in such situations it is assumed that the wavefunction continually collapses to the classical state, so that the self-referential behavior can be accommodated in the classical framework. Yet, continually evoking the wavefunction collapse procedure hides the truth that the quantum amplitudes accumulate small deviances from the real probabilities over time under the linear time-evolution.

Each time wavefunction collapse is used, the probability amplitude information is discarded. Therefore, these small differences can become hidden by invoking continual wavefunction collapse. The effect might be considered as related to the quantum Zeno effect, which observes that continuous measurement of a quantum system alters it to behave classically. In general, we postulate that the causal role of qualia may be to have a quantum Zeno-like effect, or an effect similar to intrinsic decoherence.

3.6. Information processing of the brain. A fourth class of argument comes from examining the information processing capabilities of qualia. There are proposals which state the brain is able to perform computational tasks that exceed the capabilities classical mechanics. It has been suggested this might be due to quantum structures in the brain that survive decoherence. However, alternatively it is possible that the information processing power of the brain's software (for example qualia solving the binding problem of generating a unified experience) might exceed the information processing power of the brain's hardware (a network of physical neurons which do not solve the binding problem).

The information processing required to construct a coherent three-dimensional image for example, might not be entirely due to the neural network. It might be a result of the information binding capabilities of qualia. The physical description of the brain alone i.e. the neural network; even if quantum mechanical in a limited capacity; might not contain the real power. Not much is known about qualia, but given the fact quantum states are capable of high-dimensional, parallel information processing, it is not out of the question that qualia also are able to access high-dimensional, parallel or otherwise novel information processing capabilities. Furthermore, the qualia itself may be a quantum mechanical effect, only on the non-material side of dualism.

The proposal that qualia are responsible for the information processing power of the brain makes more sense than claiming the advanced information processing capabilities are due to quantum structures that survive decoherence. In particular, the qualia remain relevant even if decoherence is dominant in the brain.

3.7. Corollary: Novel qualia. Similar to the argument for information processing power of qualia (a unique capability), it can be argued that the qualia have unique properties not predicted by the underlying physical brain-state. If this is true, when this unique information is conveyed into the real world, the only possible source of the information is from qualia, thus implying a causal role. Therefore, it should be possible to examine the properties of qualia and search for unique properties which cannot be predicted by the underlying physical matter. If such properties exist, it provides evidence that qualia play a causal role.

3.7.1. The richness of experience. The richness of the experience of qualia doesn't seem to be captured by the physical representations. For instance, ask a philosophical zombie what their favorite colour is. How can they formulate an answer without seeing the colours? The standard answer is that the perception of colour plays no causal role, because whatever is triggering a response to the question is already explained by the physical description of the neurons firing in the brain. However, as we have explained, the simultaneous physical description is already impacted by the actual presence of qualia information, and it is impossible in principle to separate the two without fine-tuning the microcausal degrees of freedom. Therefore this argument is invalid and provides no evidence for epiphenomenalism. We are forced to confront the fact that the richness of experience of qualia might not be able to be reductively explained by physical brain states.

3.7.2. Imagined colours. Another interesting example of novel qualia can be found in the space of colour perceptions. It is easy to understand how perceptions of colour could correspond in a one-to-one fashion with the spectral frequencies of light. However, it is not clear why the brain invents new colours out of combinations of different frequencies. For instance, the colour purple is not found in the visible spectrum of light. Purple is actually produced in the mind of the individual when shown a combination of red and blue. There are several perplexing aspects of this:

- (1) It is not obvious why qualia should a priori identify blue with red light to form purple. The brain has connected two opposite ends of the visible spectrum, where red corresponds to low-frequency light and blue high-frequency light, and has manufactured purple to close the loop. Connecting the colour spectrum to form a closed loop in this way might not be a unique choice.

- (2) Furthermore, the perception of the colour purple has nothing to do with the learning process of a neural network. In our natural environment, there are many green, blue and brown colours; but vivid purples are not often encountered.

It is easy to conceive that a brain in the natural environment has no prior knowledge of purple. However upon seeing purple for the first time, the brain instantly sees it as purple and this presumably happens instantaneously in a similar way for most individuals. How does the neural network of the brain instantly know how to map blue with red to form purple, across all individuals in a highly similar fashion? It seems to be a fact only obtainable outside the model of the brain as a physical learning machine, and rather comes directly from our qualia.

3.7.3. Mapping the space of qualia: Qualia and geometrical/topological information. Indeed, the whole spectrum of colour perception can be mapped out, where it forms an interesting geometrical structure. This is perplexing because what would this mapping represent if not a direct mapping of our qualia? Generating this mapping without actually experiencing the qualia does not seem possible. Furthermore, it is curious that this mapping, which forms a topological space out of the colour combinations, occurs in a similar same way for most individuals; a fact which can be studied experimentally by asking participants about their subjective experiences of colour.

We suspect that other qualia, for instance sound, smell and taste have similar properties regarding their topological mappings. If these mappings were due to the way the neural network became wired through a gradual learning process, it would be unlikely that each individual brain would independently represent the information in the same way. One would expect that different neural networks would learn to map the information in different ways.

3.7.4. Artificial qualia: Paradoxical orange. Another phenomena involving colour are the so called impossible colours. Impossible colours are those which are not part of the ordinary colour experience. They can be generated by altering the photoreceptors from their natural state. Take for example, the colour of ‘paradoxical orange’. Paradoxical orange can be generated by staring at a cyan image until the photoreceptors for this wavelength become saturated. Then, removing the original cyan image, an orange afterimage appears. This orange afterimage is perceived to be more dense than any natural orange to which it is compared.

You wouldn’t suspect a priori that paradoxical orange would occur in this arrangement. There is no logical reason that the phenomenon is experienced in the way that it is. The experience seems to come directly from the way the qualia colour our brain-states. Yet individuals are able to discuss the phenomenon, and their perceptions of it alter their actions in the real physical world, for instance by making descriptions of it.

3.8. Evolutionary argument. A fifth class of argument can be made with respect to possible evolutionary evidence. Biological organisms may have evolved to enhance and utilize qualia, not merely process information using physical brain computations. The organizational structure of the brain may actually be below optimal as an information processing network, but optimized to function more as an antennae for receiving perceptions of qualia.

One would imagine that whether the brain fundamentally performs computations or instead receives computational results from an external source (i.e. from the non-material qualia) would affect its structure and function. This is a novel argument, because it can be studied in actuality by examining the brain and thinking carefully about its organization and operation. Furthermore, we have analogue models in the form of artificial neural networks, whereby it might become apparent that the brain that acts more as a receiving device rather than a computational device in contrast to artificial neural networks.

The impact of the brain’s information processing style may be examined in the evolutionary history or across different species. The presence of qualia may have imposed a strong selection pressure toward enhancing the brain’s capabilities for receiving qualia information at the expense of alternative physical-based mechanisms of information processing. This connects the fields of physics, philosophy and evolutionary biology in a novel way.

3.9. Entropy argument. A sixth class of argument against epiphenomenalism is that type of information we impart on the physical world due to qualia appears to be of a different kind than that contained in the motion of physical matter. Consciousness is able to achieve a global picture of a situation, and understand the arrangement of physical matter and objects in the sense of relational information. Deterministic reductionist dynamics is not relational in this manner.

Using this relational information, it is possible to exert active control to remove entropy from subsystems and shift it into the external environment. Conscious perceptions essentially lets us play the role of Maxwell’s demon, shifting entropy from one side of a divide to another. It is not clear where this capacity for manipulating relational information and controlling the flow of entropy arises from, if everything is described by the linear time evolution of the wavefunction.

It is often assumed this is just due to the non-linear classical-level description of information processing. However, it is peculiar that classical mechanics is the only way we have to understand the phenomenon when the world is fundamentally quantum mechanical. Resorting to a classical-level explanation seems to indicate that we do not truly understand the phenomenon as much as commonly believed; and it may hide the uncomfortable truth that in the classical-level description, the microcausal degrees of freedom are fine-tuned, and contain hidden information which has been imposed by post-selection of the final state.

4. ARGUMENTS FOR EPIPHENOMENALISM (AND WHY THEY FAIL)

4.1. The one-to-one correlation argument. The strongest case for epiphenomenalism comes from suggesting there is a one-to-one correlation between the material states of physical matter and non-material states of consciousness. This means that any causal role is possibly just an apparent causation. For instance, we have described this interpretation as regarding the physical states like a roll of film, and the conscious states as a projection of the film which tells a story of the underlying matter, and is in a one-to-one relationship with it without affecting the underlying physical dynamical picture.

4.1.1. Counterargument 1: Begging the question. As discussed in the previous section, it is not possible to separate the physical time evolution from the qualia without begging the question (i.e. assuming that which is to be proven) and assuming from the outset that the qualia are irrelevant. The situation is that of the distinction between the counterfactual, post-selected time-evolution as compared to the free-time evolution. If one proceeds and performs this separation of qualia from the physical picture ignoring this fact, it forces the microcausal degrees of freedom to become fine-tuned, thus merely hiding the potential influences from qualia.

Why this is so problematic, is that even if qualia had a causal role, if you look back at the historical time-evolution of the system, you will see a one-to-one relationship that makes it appear as if it had no causal role. Therefore, the existence of a one-to-one relationship in prior observations gives no meaningful indication. In fact, the qualia themselves may be actively involved in forcing this one-to-one relationship. Therefore, the presence of a one-to-one relationship might on the contrary be regarded as evidence for a causal role for qualia.

4.1.2. Counterargument 2: All evidence is tainted by the co-evolution with qualia. A second, related counterargument is that that we have no truly admissible evidence for the one-to-one relationship. All evidence for the one-to-one relationship comes from real-life circumstances where a causal role for qualia may have been occurring. Therefore, all of the evidence has potentially been tainted by the presence of qualia. Furthermore, even if qualia does have a causal role, looking back at the prior time-evolution, a one-to-one relationship will be observed which makes it appear that the qualia are epiphenominal. Therefore, the problem cannot be decided based upon this relationship in general.

Because all observations of the past show this one-to-one relationship regardless of the presence or absence of a causal influence for qualia, there is no evidence in the natural world available to prove definitively whether epiphenomenalism is true or false. Therefore, epiphenomenalism is not provable in principle; it can only be disproven by examining the statistical likelihoods, and coming to the realization that it is highly unlikely for the states which occur to arise naturally in the physical world without a causal mechanism.

Taking a high-level view on the issue, it appears to be the case that epiphenomenalism has the structure of an unscientific theory. While it cannot be proven false (because the past time-evolution always shows the one-to-one relationship), there is no possible evidence for it (because this one-to-one relationship in principle tells us nothing about the causal role of qualia), and there are many additional clues (such as the transmission of information about qualia into physical world) which make it extremely implausible.

4.1.3. Counterargument 3: Novel information. The case for an epiphenominal one-to-one relationship rests on the idea that the information present in qualia does not add anything additional to the information already present in the physical brain state. We have suggested in previous sections that the information in the qualia is over and above that present in the brain state based on three separate grounds.

- (1) Firstly, the qualia may have access to an information processing capacity beyond the capabilities of the physical brain state (e.g. solving the binding problem).
- (2) Secondly, the information in qualia is of a novel character not predictable from the underlying physical brain-state (e.g. provides a rich space of experience, which is i) unique and ii) automatic, and not learned information).
- (3) Thirdly, the information may be of a relational, global type; and is related to the maintenance of entropic gradients, which support the persistence and replication of organic life.

Given these considerations, it is established that the information is present in some form. The remaining point of contention is whether this information is present in the material world, non-material world, or perhaps both.

- (1) If the information is an element of the material world, then in the epiphenominal paradigm it needs to arise out of the material world through a causal mechanism; for instance it needs to be learned through the operation of the brain as a physical neural network.
 - (a) However, it does not appear that this information ever is part of the material world in the initial state. Therefore it is not clear where the information arises from. For instance, this information is not part of the prehistoric conditions of the Earth, prior to the development of conscious entities, so it is not part of the physical environment.
 - (i) In actuality, the information is hidden in the fine-tuned microcausal degrees of freedom in the dynamical picture of epiphenomenalism; this is where the information is arising from in the interpretation.
 - (b) If the information is not present in the initial state, it is not clear what is being learned by the biological neural network. The only thing which can be learned by any learning network is information encountered in the environment.
 - (i) Again, we find that the information spontaneously arises out of the microcausal degrees of freedom, which implies fine-tuning.
- (2) If alternatively the information is just an interpretation or representation of the material world, and not actually present in the material world, then possibly there is an escape from the first situation of the information spontaneously arising.
 - (a) However, it is not clear what this information then represents, if not real information that is present in the material world.
 - (i) By analogy we know that words written on a page carry information, but this information can only be accessed when somebody reads the words. It doesn't discount the fact that the information is actually contained in the physical arrangement of words, nor the fact that the words can play a causal role e.g. the meaning of the words can change behaviour.
 - (ii) This information can a) be stored in non-conscious physical matter b) can be copied c) be transmitted between individuals by passing on the physical matter. This would suggest the information is contained in the physical matter.
 - (b) If we say that the information is not present in the physical matter, but is in the mind of the observer, this implies that the specific form and arrangements of matter which corresponds to the information spontaneously arise. Therefore, it is merely a semantical difference. We still have no explanation for why these specific forms and arrangements of matter should spontaneously arise, as they are not predicted by the conditions of the initial environment.
 - (i) The real question is then whether this specific arrangements of matter in question will cause fine-tuning when the dynamics are reversed; which is an objective scientific question with a definitive answer. It can be studied by examining the mathematics and information conservation properties of the deterministic time-evolution.
 - (ii) We suggest that these specific arrangements of physical matter can be seen to have information content which is conserved by the time-evolution; and thus, to conserve this information implies fine-tuning. If fine-tuning does occur, it can be hypothetically removed, rendering the final state lacking the specific arrangements of matter in question; thus proving epiphenomenalism to be false. This argument gets around the interpretational issues of whether this information is really contained in the material environment, or instead in the non-material interpretation or representation of the material environment.

5. FINE-TUNING

5.1. What is fine-tuning? Fine-tuning can be best understood in the de Broglie-Bohm interpretation. The de Broglie-Bohm interpretation provides a deterministic dynamics, based upon the first-order de Broglie guidance equations. The beables of the de Broglie-Bohm interpretation (e.g. a particle configuration) have a definite deterministic trajectory in configuration space. If a final particle configuration is chosen, the motion can be traced backward in time to find the corresponding initial particle configuration that will generate this final state.

The initial particle configuration may appear to be an entirely random sample from the initial joint probability distribution. However, there is hidden information contained in the positions of the initial particles, which is only revealed by operating the deterministic dynamics in the forward-direction of time once more, whereby this information becomes manifest and the corresponding final state is revealed. Indeed, one can engineer the initial

particle configuration to give any desired final state that has a non-zero probability of occurrence, via the procedure of post-selection of the final state, and then reversing the dynamics to find the corresponding fine-tuned initial state.

To understand the effect of post-selection further, suppose there is a game of billiards where the player commenced the game, and by chance managed to hit every ball into the pockets on a single turn (an extremely unlikely scenario). If we chose this final state, and then traced the motion of the billiards backward in time using the deterministic equations of motion, we would arrive at a set of microcausal degrees of freedom such as the initial position and velocity of the cue-ball.

Just looking naively at the initial position and velocity of the cue-ball, we might be misled to believe that there is nothing out of the ordinary. However, these variables contain a significant amount of hidden information, as they specify a very unique strike of the ball. When operated in reverse, the deterministic equations of motion allow information of the final state to be coiled up like a spring into the microcausal degrees of freedom of the initial state, which are in this case the initial position and velocity of the cue-ball. This hidden information becomes manifest over the subsequent forward time-evolution, when it is shown that the initial strike of the ball results in a very unique final outcome. This is all a result of the information conservation properties of the deterministic equations of motion for the system.

5.2. Relation to superdeterminism. Fine-tuning in the de Broglie-Bohm interpretation is superdeterministic. The process of fine-tuning causes information from the future state to be contained in the initial microcausal degrees of freedom, namely the initial positions of de Broglie-Bohm particles. Under the deterministic time-evolution, this allows future states to be manufactured, which consequently violates the free-will assumptions of choices of measurement basis for example. It is clear that fine-tuning in the de Broglie-Bohm interpretation can be used to evade Bell's theorem, via the superdeterminism loophole. However, philosophically this fine-tuning is undesirable, as future information is contained in the initial microcausal degrees of freedom.

5.3. Philosophical zombies are fine-tuned. As discussed in previous sections, the procedure of separating the physical dynamical picture from the non-physical qualia has a counterfactual post-selection influence on the microcausal degrees of freedom. It causes them to become fine-tuned, such that they contain hidden information of the future state, namely that the future state contains a physical description of functioning brains that appear to have states of consciousness.

Under a deterministic time-evolution, choosing a final state imposes an entire trajectory from initial state to final state, due to the unique mapping between initial and final states. Therefore, one needs to be careful not to impose fine-tuning on the initial state by making a selection of the final state.

Selecting a final state which has the presence of human beings with physical brains, already is a significant post-selection on the initial state. It is difficult to avoid post-selection and still have anything meaningful to discuss about consciousness, because everything we know about consciousness thus far is grounded in the post-selection of the final state to resemble the current world where conscious brains exist.

5.4. Removing fine-tuning. To invalidate the philosophical zombie argument, take the final conditions e.g. the final particle distribution. Reverse the deterministic dynamics back to the initial conditions. Now randomly modify the initial microcausal degrees of freedom, which will ruin the fine-tuning but still be in accordance with the statistical Born-rule probabilities. Replay the motion forward in time, and you will inevitably see that the magic is gone; the philosophical zombie will fail to reproduce the same statements about their qualia.

This argument is interesting as it turns determinism upon itself to disprove the philosophical zombie argument. Clearly the information about qualia is present at the final state, and it had to have come from somewhere. However, instead of arguing where it came from, if we reverse the deterministic time-evolution, the information has to go back somewhere. The deterministic time-evolution conserves information, so it cannot just disappear. Consequently, if the information cannot go back into the qualia (which are now removed from the picture), the information flows back into the de Broglie-Bohm particle configuration. Therefore, the particle configuration becomes fine tuned. After removing the fine-tuning, the information is destroyed permanently, and therefore it cannot subsequently arise in the final state if the dynamical picture is played forward in time once more.

In the first line of argument, we claim that information in the final state implies fine-tuning in the initial state. In this inverted line of argument, we claim that given the initial state is fine-tuned, the fine-tuning can be erased, which also erases the information from the final state. This is actually a more robust form of argument, because in the first line of argument, one reaches question of whether the information really is contained in the physical states of matter or if it is contained in the mind of the observer. In the second line of argument, it is clear that something has been erased. The world cannot be epiphenominal and have this erasure of information.

This can be understood as a purely mathematical, non-subjective question. The final arrangement of matter has a mathematically well-defined information content, based upon a suitable mathematical definition of information that is conserved. The specific arrangement of matter in the final state means the information content is higher than otherwise. Due to information conservation of the time-evolution, the initial degrees of freedom must be fine-tuned to a greater degree than otherwise. Removing the fine-tuning decreases the information content of the initial state, which consequently decreases the information content of the final state. Clearly something is altered by removing this information, and the epiphenomenalist account cannot explain how the information content is decreased by this procedure, or what is removed.

5.5. Fine-tuning as a test for consciousness. Are classical computers capable of consciousness? The Turing test is not sufficient to answer this question. Classical computers are a prime example of the philosophical zombie problem. A classical computer can conceivably tell you it has consciousness, yet on the inside it is just composed of non-conscious circuits. However, by adapting the fine-tuning argument above, you will see there evidently may be test for causally efficacious forms of consciousness, which sheds light on the problem.

Steps: Describe the final state of the computer in detail. Simulate the dynamics in the reverse direction of time to give the initial conditions. Perturb the initial conditions slightly, to remove any fine-tuning. Run the simulation in the forward direction. If the output of the simulation now lacks any information about experiences of qualia or consciousness, the original statements about consciousness likely were genuine, because there was fine-tuning involved, that has subsequently been removed. Fine-tuning implies hidden information from qualia was injected into the deterministic process through the top-down causal channel. However, if the simulation makes the same statements about consciousness as it did previously, it demonstrates that fine-tuning was not involved, and the computer was likely not conscious.

5.5.1. Deterministic classical circuits. A simple application of this principle indicates that classical circuits made from physical logic gates cannot support causally efficacious consciousness, because they are robust in the initial conditions and not capable of fine-tuning.

Consider a computational circuit made from many dominoes arranged in a pattern of logic gates. It is evident that the domino computer is robust in the initial conditions. For instance, slight modification of the positions of the initial dominoes, e.g. rotating their angles slightly, will result in the same fall pattern, giving the same computational output. You could take the final output and trace the initial conditions back, slightly adjust the positioning of the initial dominoes, run the device again, and you will get the same answer. Due to this robustness in the microcausal degrees of freedom, the system is not capable of becoming fine-tuned to the level at which the fine-tuning affects the output state. Therefore, there is no room in the physical description for a causal role for qualia.

As seen in the above description, fine-tuning appears to be closely connected to the robustness and information channel capacity of the input states. What do we mean by robustness? We mean that the initial dominoes have some redundancy in their physical positioning. You can move them backwards or forwards slightly or rotate them, and it won't affect the outcome of the circuit. What do we mean by channel capacity? The information is a single binary unit traveling down the chain of dominoes. There is only one real piece of information in each "wire" of the circuit, and the microcausal degrees of freedom are irrelevant to the outcome.

Due to the limited channel capacity, there are no relevant microcausal degrees of freedom. The entire system is constructed to be a direct mapping from inputs to outputs. In particular, there is no cascading step, where the microcausal conditions get amplified into macroscopic conditions. Taking all of this into consideration, it implies that there is no possibility for relevant fine-tuning to be hidden in the initial arrangements dominoes in the circuit.

5.5.2. Turing machines are not conscious. Similar to the domino circuit, it is clear that a hypothetical Turing machine i.e. an infinite tape with a reading device, cannot have causally efficacious consciousness. The Turing machine describes a deterministic set of instructions that is read in sequence. Because the scenario is abstracted away from the microcausal physical picture as a logical thought experiment, there are no microcausal degrees of freedom present at all. Therefore, the system is not capable of fine-tuning.

One could choose a final state for the Turing machine, then hypothetically reverse the time-evolution, and reach the corresponding initial state. Then alter nothing, because there are no microcausal degrees of freedom available to alter. Run the device again, and exactly the same answer will be produced. There is only one unalterable path from the initial conditions to the final conditions. Nowhere in this process can further causal influences from qualia can be injected into the deterministic process, because additional causal influences require the possibility for fine-tuning.

5.5.3. *How the human brain is able to be conscious.* In the human brain, the complex network of neurons has a cascade of firings which is highly sensitive to the initial conditions. Essentially, there needs to be an information bottleneck where the outcome could be decided one of many ways, and the answer comes down to the microcausal degrees of freedom. This dependence upon the microcausal degrees of freedom e.g. the specific arrangement of de Broglie-Bohm particles, creates the possibility for fine-tuning in the deterministic paradigm, which allows room for causally efficacious consciousness in the dynamical picture.

5.5.4. *How to make a conscious computer.* To generate consciousness within a computer, a necessary condition is to have a cascading mechanism which will allow for amplification of fine-tuned microcausal degrees of freedom into macroscopic outcomes. The computer circuit cannot be a simple deterministic path from macroscopic inputs to macroscopic outputs. It may be possible to create consciousness within a computer circuit with the right setup, but current setups are insufficient as they are based upon classical algorithms with no indeterminacy or amplification of the microcausal degrees of freedom.

Standard classical computers cannot not be conscious, because deterministic classical algorithms are a direct path from inputs to outputs, leaving no room for additional causal influences to be injected in the forward picture of the motion, or fine-tuning to occur in the backward picture of the motion. This rules out the possibility for causally efficacious forms of consciousness in these systems.

While we cannot in principle rule out the possibility that deterministic classical circuits supports an epiphenomenal consciousness, it does seem highly implausible as it is in disagreement with commonsense reductionist intuitions that a system which can be decomposed into deterministic macroscopic parts cannot be conscious.

However, the requirement for amplification of the microcausal degrees of freedom is only a necessary condition that can be used to disprove certain systems are conscious. It cannot be used to prove a system is conscious, and it is not clear what other requirements are necessary to make consciousness an inevitable conclusion.

6. THE COMPLETENESS OF QUANTUM MECHANICS

6.1. **Born-rule probabilities are a qualia.** The experience of Born-rule probabilities may themselves be regarded as a form of qualia. The only reason the Born rule probabilities are observed is because we perceive the world through our senses, including the qualia of sight of experimental measurement results (for example observing flashes on a screen during the double-slit experiment).

However, there are other qualia besides the statistical frequency of probabilistic events. The rich variety of other qualia also require explanation. In this sense, quantum mechanics may not be a complete theory. To complete the quantum description, it might be necessary to include these other qualia as influences upon the wavefunction collapse procedure or the de Broglie-Bohm particle configuration.

6.2. **Born-rule probabilities are not compatible with qualia.** There are branches of the wavefunction which are incompatible with the Born-rule. Similarly, there are branches of the wavefunction which are incompatible with qualia. The wavefunction merely sets up a space of possible worlds, and the vast majority of them are unrealistic. So the essential question is, “Are all of the possible Born-rule worlds compatible with qualia?”. We believe the answer is no. The worlds compatible with qualia are a subset of the Born-rule worlds. This is clear because:

- (1) The wavefunction has no knowledge of qualia. Nor does the wavefunction collapse procedure have knowledge of qualia. Therefore the Born-rule probabilities have no knowledge of qualia.
- (2) Therefore, no information about qualia is imparted into the final states defined by the Born-rule.
- (3) However, it is evident that qualia does impart information into the final state; therefore, not all Born-rule states can be compatible with qualia.

A mechanism is required to ensure only the Born-rule worlds compatible with qualia are selected. We suggest that the problem may be addressed by introducing a causal role for qualia, broadly defined.

6.3. **The intrinsic decoherence connection.** We have highlighted previously in this paper the connection between the causal role of qualia and the fact that quantum mechanics has difficulty explaining non-linear and self-referential phenomena. The quantum formalism typically resorts to a classical-level description to explain these cases (for instance describing the situation at the level of classical neurons in the brain). However, in light of the possible causal role for qualia, it is suggestive that this causal mechanism may be having the effect of making the quantum state behave more classically. This enables the effect to be explained without leaving the quantum description.

Consequently, we suggest that the role of qualia may be to have a type of intrinsic decoherence effect, or alternatively a type of quantum Zeno effect; both of which are mechanisms which would make the quantum state behave more classically.

6.4. The connection to quantum subsystems. We find it particularly intriguing to suggest a connection between qualia, which is an internal point of view, and non-Markovianity of quantum subsystems, which is an incompatibility between the time evolution of the total quantum system and the time evolution of the subsystem.

The reason why this might be so is that qualia are related to the metaphysical property of “What it’s like to be a subsystem?”; for instance, what it’s like to be the ‘subsystem’ of a human brain. However, the time-evolution of a highly entangled quantum subsystem is non-Markovian, which is a mysterious property that prevents the subsystem from having a simple ontological representation.

Therefore it appears that in quantum mechanics, there is a dichotomy between the internal point of view from the perspective of subsystems, and the external point of view from the perspective of the total system. This mirrors the dichotomy between the internal perspective of subjective consciousness, and the external perspective which views the brain in terms of the material physical picture in the context of the environment.

The phenomenon of non-Markovianity also prevents a reductionist description of the subsystem, as non-Markovian subsystems describe a complex network of information flow that cannot be reduced to parts [3, 4]. The fact that the description is non-reductive may be connected with consciousness, as it is difficult to envisage that a collection of individual classical components that have a reductive explanation (e.g. individual classical neurons) are capable of being conscious.

Certainly, due to the myriad of interactions occurring, the structures within the brain are highly entangled, despite being decoherent. Therefore, it is not out of the realm of possibility that non-Markovianity is occurring within the brain, and that non-Markovianity plays a role in consciousness.

Furthermore, if the total quantum state gets pulled in the direction of the subsystem; for example, the joint probability density becoming closer to the product of the marginal probability densities of the subsystem and environment; that will look like an intrinsic decoherence is occurring. From the previous discussions on non-linear and self-referential processes, this is the type of effect which is required, which provides further evidence that quantum subsystems and non-Markovianity may be involved in consciousness.

6.5. A general causal mechanism? We have claimed in previous sections that the causal role for qualia may allow physical subsystems to violate natural entropy gradients, and minimize their internal entropy at the expense of the environment. For example, qualia evidently allow human brains to comprehend information and meaning, and give rise to an understanding of the physical world in a global, relational sense. However, deterministic linear dynamical physical processes are local, and blind to relational information. Therefore, it is a somewhat paradoxical phenomena potentially resolved by including a causal role for qualia.

However, it is evident that the problem is not necessarily restricted to conscious states or qualia. We ask whether non-conscious can also access qualia-like features present in the natural world, which enable this type of behaviour on a smaller scale? Perhaps, this type of information processing is a general causal mechanism in nature.

Indeed, the existence of a basic causal mechanism independent of consciousness seems likely to be the case in light of evolution. It is highly unlikely that consciousness came about suddenly. More likely, early forms of life began to use a basic causal mechanism responsible for the effect, and its use became progressively more refined over the course of evolution. This argument is interesting, because it brings the debate outside of the question of consciousness and grounds it in terms of information, thermodynamics and causality. The debate is a question about the possible causal mechanisms in nature in general.

These questions are reminiscent early discussions of “What is life?”, for instance Schrödinger’s seminal paper [5] on the topic. The problem has always been to explain how a living dynamical system can internally minimize entropy at the expense of the external environment. Some early conceptions for how this phenomena occurs were proposed, for instance in the discovery of the formation of spontaneous order in non-linear systems due to dissipative structures; for which Prigogine won the 1977 Nobel Prize in Chemistry, and has now evolved into a large field of study.

However, we should keep an open mind and recognize that the case may not be closed. The problem remains that the quantum time-evolution is linear, and a mechanism for non-linearity beyond the wavefunction collapse procedure is required to explain the phenomenon. It does not seem evident *prima facie* that a linear system can minimise entropy in this manner. Meanwhile, the potential causal role for qualia has been overlooked, leaving an opportunity to reexamine the question.

Perhaps these hypothetical qualia-like effects have allowed biological systems of all varieties to beat the statistical odds, and remove entropy from their subsystems, thus creating internal order which supports self-replication and life. All of these biological systems are acting like a Maxwell’s demon, and we suggest that the explanation might not be found in the standard linear time-evolution of quantum mechanics, but in the influence of non-material effects upon the wavefunction collapse process (for instance via a causal influence of qualia on the de Broglie-Bohm particle configuration).

This brings the discussion back to the suggestion that the effect of qualia is to act as a type of intrinsic decoherence, or alternatively quantum Zeno-like effect on the quantum state. These mechanisms of intrinsic decoherence or a quantum Zeno-like effect can easily be conceived as a general mechanism that operates independently of conscious experience, and therefore may impact the functions of non-sentient organic life as well as sentient organic life.

7. CONCLUSIONS

This paper has made the case that qualia (i.e. conscious experiences) have a causally efficacious role, and are not merely an epiphenomenon. The common view is that the deterministic equations of motion leave no room for additional causal influences from qualia. However, such a view contains an error in regarding the dynamics as a closed form of determinism in the forward direction of the time-evolution.

The wavefunction is a branching process. Therefore, the type of determinism is an open form, and there is room in the description for a causal role of qualia to guide the de Broglie-Bohm particle configuration down a specific wavefunction branch. Alternatively, this can be understood as an influence upon the wavefunction collapse process in the Copenhagen interpretation, as statements made within the de Broglie-Bohm interpretation have their equivalent in the Copenhagen interpretation.

The evidence for a causal role of qualia is stark. This evidence includes:

- (1) Arbitrariness of qualia if they do not play a causal role; therefore, allowing qualia to be hypothetically altered in thought experiments.
 - (a) Including philosophical zombie thought experiments.
 - (b) Including thought experiments where a region of the brain is replaced with a classical computer circuit. These thought experiments violate intuition, and it is not clear that the physical system can act in the same way upon alteration of the qualia.
- (2) The presence of information about qualia which is able to enter the physical environment through an unknown channel.
 - (a) Including “zombie island” thought experiments, where spontaneous emergence of statements about consciousness occur.

It is not clear how this information is able to enter the physical environment without it being sourced from the qualia.

- (3) The presence of non-linear and self-referential behavior, despite the quantum mechanical description being linear and unitary. Noting that quantum mechanics explains these circumstances by invoking wavefunction collapse, and therefore relies upon a classical description.
- (4) Novel information provided by qualia.
 - (a) Including novel information processing capabilities in the brain e.g. solving the binding problem of consciousness.
 - (b) Including novel features of qualia e.g. the richness of qualia experiences, imagined qualia that do not have a direct relation to physical states, geometrical and/or topological mappings of the space of qualia. Furthermore noting that this novel information enters the physical environment through reports of qualia experiences.
- (5) Evolutionary arguments, that possible evolutionary evidence for selection pressures may be observed in the structure and function of the brain, which may be an area of future research.
- (6) Entropy arguments, that qualia enables physical matter to violate typical entropy gradients, though the access to relational, top-down causal information which is not part of the reductionist dynamical picture.

Meanwhile, the evidence for epiphenomenalism is found to be lacking. This possible evidence includes:

- (1) The argument that there is a one-to-one correlation between physical states and qualia, such that any causation is only an apparent causation.
 - (a) Where this argument is found to be assuming that which is to be proven, as it is examining the post-selected, counterfactual state which has co-evolved with the presence of qualia.
 - (b) Where we recognize that it is impossible in general to remove the counterfactual post-selection, as all current evidence is based upon the post-selected state of the current environment that includes qualia.
 - (c) Where we recognize that the novel information provided by qualia is not part of the physical environment initially, yet it enters the physical environment during the time evolution and is present in the final state.
- (2) Philosophical zombie thought experiments.
 - (a) Where we find that the microcausal degrees of freedom are fine-tuned, due to counterfactual post-selection of the final state.

- (b) Where we find that removing the fine-tuning in the initial state will destroy the qualia information in the final state.

After establishing the evidence for and against epiphenomenalism, we arrive at the conclusion that qualia must have a causal role in the dynamics. Using this understanding, we further examine the role of fine-tuning in the dynamical picture, which occurs if the causal role of qualia is ignored.

Firstly, the philosophical zombie argument for epiphenomenalism is found to be insufficient, as it is impossible to separate the material physical description from the non-material qualia without imposing counterfactual post-selection, which causes fine-tuning of the microcausal degrees of freedom. Fine-tuning occurs due to the deterministic dynamics, which results in a one-to-one mapping between initial states and final states. Thus choosing a final state which describes philosophical zombies causes fine-tuning of the initial microcausal degrees of freedom (e.g. positions of de Broglie-Bohm particles). Undesirable hidden information about the future state is present in the microcausal degrees of freedom due to fine-tuning.

Secondly, fine-tuning is found to be intimately linked to the presence of causally efficacious consciousness. It is evident that classical computer circuits; which are incapable of having any meaningful fine-tuning; are not capable of causally efficacious consciousness. Furthermore, reductionist arguments against such circuits having epiphenominal consciousness appear quite strong, therefore it is likely these systems cannot support consciousness in general. Understanding this link between consciousness and fine-tuning highlights the difference between classical circuits and conscious biological brains which can support fine-tuning.

We continue the discussion by highlighting where the quantum formalism may not be complete. We show that the Born-rule can be considered a form of qualia, and that the remaining qualia should not be ignored in the wavefunction collapse procedure. Furthermore, it is argued that not all wavefunction branches compatible with the Born-rule are compatible with the continuous, dynamical experience of qualia across time. The effect of the causal role for qualia is to select only the Born-rule states which are simultaneously compatible with qualia.

Furthermore, it is proposed that qualia may be having a type of intrinsic decoherence effect, or quantum Zeno effect; both of which would make the quantum mechanical probabilities appear more classical. This would resolve the paradox of resorting to a classical-level description to explain non-linear and self-referential behaviour in quantum mechanics. Additionally it is proposed that qualia and consciousness may be connected to non-Markovianity in quantum subsystems. This is motivated by the recognition that qualia is the property of ‘what it’s like to be a subsystem’, whilst non-Markovianity causes physical subsystems to have a non-reducible ontological description, thus avoiding reductionist arguments against consciousness.

Finally, we reflect upon the role that qualia plays in maintaining entropy gradients in conscious systems, and propose that the effect may be part of a general causal mechanism, not isolated to the case of consciousness entities. It is suggested this causal mechanism has enabled non-conscious organic life to maintain low states of internal entropy and sustain and replicate itself despite the underlying physical dynamical picture not having access to top-down, relational information processing mechanisms.
