Abstract

In recent years, the dominance of machine learning in stock market forecasting has been evident. While these models have shown decreasing prediction errors, their robustness across different datasets has been a concern. A successful stock market prediction model not only minimizes prediction errors but also showcases robustness across various data sets, indicating superior forecasting performance. This study introduces a novel multiple lag order probabilistic model based on trend encoding (TeMoP) that enhances stock market predictions through a probabilistic approach. Results across different stock indexes from nine countries demonstrate that the TeMoP outperforms the state-of-art machine learning models in terms of predicting accuracy and stabilization.

Keywords: stock market forecasting, robustness, prediction errors, trend encoding, multiple lag order

1. Introduction

Time series prediction is an evergreen topic that spans across various application domains. For instance, it finds applications in fields such as economics (Masini et al., 2023), finance (Cui et al., 2023), traffic flow (Lv et al., 2014), and energy (Wang et al., 2017), among others. Time series trend forecasting serves as the foundation of time series prediction. It involves using historical data to forecast whether future data will exhibit an upward trend. Accurately capturing the trend of a time series is essential for achieving precise time series forecasts. Therefore, designing a model with superior forecasting performance for time series trend forecasting holds significant value in practical applications.

In practical applications, a good stock market prediction model not only has a small prediction error, but this small prediction error is also well robust across different data sets. However, existing models often struggle to meet these two characteristics at the same time. Existing time series trend forecasting models can be broadly categorized into four types based on their methodological principles: statistical models (Ray et al., 2023), machine learning models in a narrow sense (Costa and Pedreira, 2023; Yin et al., 2023), deep learning models (Yang et al., 2022), and fuzzy time series models (Bitencourt et al., 2023). Compared to the other models, deep learning models and fuzzy time series models demonstrate less prediction errors on the test set. However, poor robustness and black-box nature of deep learning models and the information leakage issue of fuzzy time series models have been criticized.

Therefore, for time series trend forecasting, this paper proposes a multiple lag order probabilistic model based on trend encoding (TeMoP) inspired by fuzzy time series models and random forests. In fuzzy time series modeling, time series forecasting is achieved by blurring the time series into different degrees and analyzing the patterns between the different degrees. Therefore, in addition to using the original features, this paper also obtains the trend features of the time series through trend encoding and analyzes the patterns between different trend features, which in turn reduces the prediction errors. In random forests, several different models are trained based on different bootstrap sets, and then the results of these models are combined thereby improving the robustness of predictive performance. Influenced by random forests, to solve the problem of poor robustness of models trained by samples with a certain lag order, this paper trains different models based on samples

with different lag orders, and then combines the results of these models to improve the robustness of prediction performance.

Thus, in principle, TeMoP offers the following advantages: (1) Excellent robustness. Unlike classical models trained by samples with a certain lag order, TeMoP integrates the results of models trained by samples with different lag order, which enhances robustness. (2) Small prediction errors. The introduction of trend features reduces the prediction errors of TeMoP.

Due to its inherent characteristics such as high volatility and non-normality, stock data is renowned for being difficult to predict. However, effective prediction of stock data is crucial for providing sound investment decision recommendations. Therefore, this study selects the stock trend prediction as the application scenario. By analyzing stock data from different types of financial markets, it indicates that TeMoP outperforms the comparative models in terms of prediction errors. Furthermore, unlike the comparative models whose prediction errors fluctuates wildly across different data sets, TeMoP demonstrates good robustness.

The main innovations and contributions of this paper are as follows:

- This study proposes a multiple lag order probabilistic model based on trend encoding (TeMoP) for forecasting time series trends. In principle, this model shows good robustness and small prediction errors.
- Building upon the background of stock trend prediction, this study analyzes the superiority of TeMoP in terms of prediction errors and robustness across multiple data sets from various types of financial markets.

The remaining sections of this paper are structured as follows: The second section 2 reviews and analyzes related research. The third section 3 provides a detailed introduction to the principles of TeMoP. The fourth section 4 conducts a comprehensive comparative analysis of the experimental results. The fifth section 5 summarizes the entire paper and provides outlooks for future research. The last section consists of the references.

2. Literature review

For a long time, research on time series trend forecasting has been abundant. Based on different methodological principles, existing research results

can be classified into four categories: statistical models (SM), machine learning models in a narrow sense (ML), deep learning models (DL), and fuzzy time series models (FTSM).

The complexity of the real world often leads to statistical models failing to meet their assumptions, resulting in poor prediction performance on realworld data sets (Li et al., 2023; Wang et al., 2022, 2023). Unlike statistical models, machine learning models are data-driven. For example, Random Forests, a classic model in machine learning, improve both data utilization efficiency and robustness by sampling from the original data set using bootstrapping and integrating the output of multiple models (Jain and Jana, 2023; Sun et al., 2024; He et al., 2024). Deep learning methods are also data-driven. Despite small prediction errors on real-world data sets, they are criticized for poor robustness (Ma et al., 2022; Zhao et al., 2023; Pan et al., 2023). Unlike the previous models, fuzzy time series models are designed based on fuzzy mathematics principles Silva et al. (2020). Fuzzy time series modeling mainly involves: (1) defining the universe of discourse and linguistic variables, (2) fuzzification, (3) extracting fuzzy temporal patterns, (4) building a fuzzy rule base, (5) making predictions based on the fuzzy rule base, and (6) defuzzification.

Among numerous researches, fuzzy time series models and deep learningbased decomposition-ensemble models exhibit less prediction errors on test Compared to deep learning, fuzzy time series models constitute a niche research direction. Existing researches mainly fall into two categories. One is innovative research on the theoretical methods of fuzzy time series models (Erazo-Costa et al., 2024; Wang et al., 2024). For instance, de Lima Silva et al. (2019) proposes probabilistic weighted fuzzy time series model (PWFTS), which not only integrates point, interval, and probabilistic forecasting in the same model, but also is a new non-parametric, data driven, and highly accurate forecasting method. The other is innovative research on the practical applications of fuzzy time series models (Sadaei et al., 2019; Severiano et al., 2021). For example, Bitencourt et al. (2023) combines Autoencoder with weighted multivariate fuzzy time series model (WMVFTS) (de Lima e Silva et al., 2019) for high-dimensional time series forecasting in the Internet of Energy (IoE), and the proposed model achieves excellent prediction performance. Through extensive comparative analysis, these researches are all based on an open-source Python library—pyfts (Silva, Lucas, Sadaei, and Guimarães, Silva et al.). However, a study of the pyfts source code reveals a flaw in information leakage during the prediction process.

That is, pyfts utilizes future information data during prediction, resulting in excellent performance of the prediction results based on pyfts.

Similarly, the deep learning-based decomposition-ensemble method also suffers from information leakage (He et al., 2022, 2021). The main steps of this method are as follows: (1) decompose the original time series into multiple sub-sequence using sequence decomposition algorithms, (2) model and predict each sub-sequence separately, and (3) sum the predictions of each sub-sequence to obtain the final prediction result. Common sequence decomposition algorithms include Seasonal and Trend decomposition using Loess (STL) (He et al., 2021; Zeng et al., 2024), Empirical Mode Decomposition (EMD) (Jun et al., 2017; Xiang et al., 2018), Complete EEMD with Adaptive Noise (CEEMDAN) (Li et al., 2024; Song et al., 2024), and Variational Mode Decomposition (VMD) (Nasiri and Ebadzadeh, 2023; Zhang et al., 2023). This method often exhibits small prediction errors on the test set. For instance, Liang et al. (2022) first decomposes gold prices into multiple sub-sequences using CEEMDAN, then combines Long Short term Memory (LSTM), Convolutional Neural Networks (CNN), and Convolutional Block Attention Module (CBAM) to predict each sub-sequence, and finally sums the prediction results of all sub-sequences to obtain the final prediction results. Experimental results shows that, on the test set, the proposed model achieves a determination coefficient (R²) exceeding 0.999 and Mean Absolute Percentage Error (MAPE) below 0.3%. In the method, the test set, which should be unknown, is treated as known, thus inevitably causing the leakage of future information.

In summary, although fuzzy time series models and deep learning-based decomposition-ensemble methods exhibit small prediction errors on the test set, their flaws in information leakage render these models lack practical significance.

Therefore, based on the shortcomings of existing models, this study designs a multiple lag order probabilistic model based on trend encoding TeMoP for time series trend prediction, which performs excellently in terms of robustness, prediction errors, and other aspects from the perspective of practical application. The next section 3 will focus on introducing the principles of TeMoP.

Table 1: Summary of symbols in TeMoP $\,$

Symbol	Meaning	Expression
Z m	Time series data for training Sample size threshold. Generally, $m = 50$	$\{z_1, z_2,, z_{n-1}\}$
$rac{q}{x^i_i}$	Maximum lag order of samples A sample with lag order <i>i</i> .	$x_i^i=(z_{i_+}$,, z_{i} ,,, z_{i} ,).
y_{j}^{c}	A sample label with lag order i .	$y_{j}^{i}=(z_{j_{n}}).$
$ ilde{\Omega}^i_i$	A set of samples with lag order i .	$\vec{\Omega}^i = \{x_j^i j = 1, 2,, n - i - 2\}.$
$t(x_j^i)$	Trend encoding function for samples.	
$t_i^{N_i}$	A subset of samples with lag order i . Trend feature vectors of Ω_i^i	$M_l^i \equiv \{X_j^i \mid \nabla t(X_j^i) \equiv t(X_l^i)\}. \ t(\Omega_l^i) \equiv \{t(X_l^i) \mid \forall X_l^i \in \Omega_l^i\}.$
$+\Omega_l^i$	A subset of positive samples with lag order i .	$+\Omega_l^i = \{x_j^i \forall t(x_j^i)^j = t(x_h^i), t(y_j^i) = 1\}.$
$-\Omega_l^{ec{i}}$	A subset of negative samples with lag order i .	$-\Omega_l^i = \{x_j^i \forall t(x_j^i) = t(x_h^i), t(y_j^i) = -1\}.$
$oldsymbol{\mu}(\Omega)$	Sample mean of set Ω .	
$\mathbf{\Sigma}(\Omega)$	Sample covariance of set Ω .	
$ \Omega $	Number of all elements in set Ω .	
$N(\Omega)$	Normalization function in set Ω .	
Z	Time series data for test.	$\{\hat{z}_{n-q}, \hat{z}_{n-q+1},, \hat{z}_{n-1}\}.$
$U_{\Omega_{i}^{i}}(x_{h}^{i})$	Similarity of $t(x_h^i)$ and $t(\Omega_l^i)$.	
$S(t(y_0^i) = 1 x_0^i \in \Omega_l^i, t(x_0^i)$	$S(t(y_0^i)=1 x_0^i\in\Omega_t^i,t(x_0^i))$ Score of $t(y_0^i)=1$ computed based on $t(x_0^i)$ when	
	$x_0^i \in \Omega_l^i$.	
$S(t(y_0^i) = 1 x_0^i \in \Omega_l^i, x_0^i)$	Score of $t(y_0^i) = 1$ computed based on x_0^i when	
	$x_0^t \in \Omega_l^t$.	
$S(t(y_0^i) = 1 t(x_0^i))$ $S(t(y_0^i) = 1 x_0^i)$	Score of $t(y_0^i) = 1$ computed based on $t(x_0^i)$. Score of $t(n_t^i) = 1$ computed based on x_t^i	
$S(t(y_0^i) = 1)$	Score of $t(y_0^0) = 1$.	

Table 2: Summary of functions in TeMoP

Function	Description	Expression
$t(z_i)$	Trend encoding function for scalar	$t(z_i) = \begin{cases} -1, & z_i < z_{i-1}, \\ 1, & z_i \ge z_{i-1}, \end{cases}$
$t(z_{i_1},z_{i_2},,z_{i_s})$	$(z_{i_1},z_{i_2},,z_{i_p})$ Trend encoding function for vector	$t(z_{i_1},z_{i_2},,z_{i_p})=(t(z_{i_2}),t(z_{i_3}),,t(z_{i_p})).$
$I[x_i = y_i]$	Indicator function	$I[x_i = y_i] = \begin{cases} 1, & x_i = y_i, \\ 0, & others. \end{cases}$
$x \vec{\wedge} y$	Overlap of vectors	$x \vec{\wedge} y = \frac{1}{n} \sum_{i=1}^{n} I[x_i = y_i].$
$M(x_j^i,+\Omega_l^i)$	Mahalanobis Distance between x_j^i and $+\Omega_l^i$.	$M(x_j^i, +\Omega_l^i) = \sqrt{(x_j^i - \mu(+\Omega_l^i))^T \Sigma(+\Omega_l^i)^{-1}(x_j^i - \mu(+\Omega_l^i))}.$
Dtp(u)	Mapping the Mahalanobis distance to values between $Dtp(u) = \frac{2}{1+e^u}$. [0,1].	$\operatorname{in} Dtp(u) = \frac{2}{1 + e^u}.$

Figure 1: Algorithm of TeMoP.

3. Methodology

In this section, the principles of TeMoP are described in detail. Table 1 and Table 2 show summary of symbols and functions associated with TeMoP respectively. Figure 1 is flowchart of the algorithm for TeMoP. According to the Figure 1, TeMoP is mainly divided into a training section and a testing section. $Z = \{z_1, z_2, ..., z_{n-1}\}$ is time series data for training. And $\hat{Z} = \{\hat{z}_{n-q}, \hat{z}_{n-q+1}, ..., \hat{z}_{n-1}\}$ is test data for calculating $P(\hat{z}_n \geq \hat{z}_{n-1})$ with \hat{z}_n unknown.

3.1. Training

For time series prediction, traditional models firstly have to determine lag order of samples. Unlike the traditional models, TeMoP starts training from the lag order equal to 1, and determines the value of maximum lag order adaptively by setting the judgment condition and nature of data. The training process is as follows.

- 1: Let i = 1.
- **2:** Slide the windows with length i+1 to obtain samples and labels like Equation 1.

$$\begin{pmatrix} x_1^i & \vdots & y_1^i \\ x_2^i & \vdots & y_2^i \\ \vdots & & \ddots & \vdots \\ x_{n-i-1}^i & \vdots & y_{n-i-1}^i \end{pmatrix} = \begin{pmatrix} z_1 & \dots & z_i & \vdots & z_{i+1} \\ z_2 & \dots & z_{i+1} & \vdots & z_{i+2} \\ \vdots & & \ddots & & \vdots \\ z_{n-i-1} & \dots & z_{n-2} & \vdots & z_{n-1} \end{pmatrix}$$
(1)

- **3:** Let $\Omega^i = \{x_j^i, j = 1, 2, ..., n i 1\}$. Then split Ω^i to obtain $\Omega^i_l = \{x_j^i | \forall t(x_j^i) = t(x_h^i)\}$ according to $t(x_j^i)$ and return $\{t(\Omega^i_l) | \forall l\}$.
- **4:** Judge whether there exists l such that $|\Omega_l^i| < m$. If yes, then stop and let i = i + 1 and repeat steps 2 to 4. If no, then continue next steps.
- **5:** Split $\Omega_l^i = \{x_j^i | \forall t(x_j^i) = t(x_h^i)\}$ according to $t(y_j^i)$. Let $+\Omega_l^i = \{x_j^i | \forall t(x_j^i) = t(x_h^i), t(y_j^i) = 1\}$ and $-\Omega_l^i = \{x_j^i | \forall t(x_j^i) = t(x_h^i), t(y_j^i) = -1\}$.
- **6:** Compute and return

$$\begin{split} &\{(|+\Omega_l^i|,|-\Omega_l^i|)|\forall l\},\\ &\{(\mu(+\Omega_l^i),\mu(-\Omega_l^i))|\forall l\},\\ &\{(\Sigma(+\Omega_l^i),\Sigma(-\Omega_l^i))|\forall l\},\\ &\{(N(+\Omega_l^i),N(-\Omega_l^i))|\forall l\}. \end{split}$$

7: Return

$$\begin{split} q &= i - 1, \\ & \{ \{ t(\Omega_l^i) | \forall l \} | i = 1, ..., q \}, \\ & \{ \{ (|+\Omega_l^i|, |-\Omega_l^i|) | \forall l \} | i = 1, ..., q \}, \\ & \{ \{ (\mu(+\Omega_l^i), \mu(-\Omega_l^i)) | \forall l \} | i = 1, ..., q \}, \\ & \{ \{ (\Sigma(+\Omega_l^i), \Sigma(-\Omega_l^i)) | \forall l \} | i = 1, ..., q \}, \\ & \{ \{ (N(+\Omega_l^i), N(-\Omega_l^i)) | \forall l \} | i = 1, ..., q \}. \end{split}$$

3.2. Testing

In this section, based on results of training, we use $\{\hat{z}_{n-q}, \hat{z}_{n-q+1}, ..., \hat{z}_{n-1}\}$ to compute $P(\hat{z}_n \geq \hat{z}_{n-1})$ with \hat{z}_n unknown. The calculation process is as follows.

- 1: Let i = 1.
- **2:** Let $x_0^i = \{\hat{z}_{n-i}, \hat{z}_{n-i+1}, ..., \hat{z}_{n-1}\}, y_0^i = \hat{z}_n$ and compute $t(x_0^i)$.
- 3: Compute $U_{\Omega_i^i}(x_0^i)$.

$$U_{\Omega_l^i}(x_0^i) = t(x_0^i) \vec{\wedge} t(\Omega_l^i). \tag{2}$$

4: Compute $S(t(y_0^i) = 1 | x_0^i \in \Omega_l^i, t(x_0^i))$ and $S(t(y_0^i) = 1 | x_0^i \in \Omega_l^i, x_0^i)$ based on Equation 3 and Equation 4 respectively. $S(t(y_0^i) = -1 | x_0^i \in \Omega_l^i, t(x_0^i))$ and $S(t(y_0^i) = -1 | x_0^i \in \Omega_l^i, x_0^i)$ ditto.

$$S(t(y_0^i) = 1 | x_0^i \in \Omega_l^i, t(x_0^i)) = \frac{| + \Omega_l^i| + 1}{| + \Omega_l^i| + | - \Omega_l^i| + 2}$$
(3)

$$S(t(y_0^i) = 1 | x_0^i \in \Omega_l^i, x_0^i) = Dtp(M(x_0^i, +\Omega_l^i))$$
(4)

5: Compute $S(t(y_0^i) = 1|t(x_0^i))$ and $S(t(y_0^i) = 1|x_0^i)$ based on Equation 5 and Equation 6 respectively. $S(t(y_0^i) = -1|t(x_0^i))$ and $S(t(y_0^i) = -1|x_0^i)$ ditto.

$$S(t(y_0^i) = 1 | t(x_0^i)) = \sum_{l} U_{\Omega_l^i}(x_0^i) \cdot S(t(y_0^i) = 1 | x_0^i \in \Omega_l^i, t(x_0^i)), \quad (5)$$

$$S(t(y_0^i) = 1 | x_0^i) = \sum_{l} U_{\Omega_l^i}(x_0^i) \cdot S(t(y_0^i) = 1 | x_0^i \in \Omega_l^i, x_0^i).$$
 (6)

6: Compute $S(t(y_0^i) = 1)$ based on Equation 7. $S(t(y_0^i) = -1)$ ditto.

$$S(t(y_0^i) = 1) = S(t(y_0^i) = 1|x_0^i) + S(t(y_0^i) = 1|t(x_0^i)).$$
 (7)

7: Judge whether i = q. If yes, compute $P(\hat{z}_n \geq \hat{z}_{n-1})$ based on Equation 8. If no, let i = i + 1 and repeat steps 2 to 7.

$$P(\hat{z}_n \ge \hat{z}_{n-1}) = P(t(\hat{z}_n) = 1) = \frac{e^{\sum_{i=1}^q S(t(y_0^i) = 1)}}{e^{\sum_{i=1}^q S(t(y_0^i) = 1)} + e^{\sum_{i=1}^q S(t(y_0^i) = -1)}}.$$
 (8)

Caution: Samples need to be normalized before calculating the Mahalanobis distance. After normalization, the $\Sigma(+\Omega_l^i)$ takes values close to the unit matrix E, which leads to large values of $\Sigma(+\Omega_l^i)^{-1}$ and further leads to large computed Mahalanobis distances. Therefore, in order to solve the above issue, $\Sigma(+\Omega_l^i) + 0.1 \cdot E$ is used to instead of $\Sigma(+\Omega_l^i)$.

3.3. Why

The above subsections answers how TeMoP can be utilized for training and testing, and this section provides a detailed explanation of why TeMoP is so designed.

In the real world, time series data often exhibit non-stationary properties. Therefore, models trained based on samples with a certain lag order tend to exhibit poor robustness.

Therefore, in order to solve the above problem, this paper firstly computes the maximum lag order by the nature of the data. Then, this paper synthesize results of various models trained based on samples with different lag order not exceeding the maximum lag order, as shown in Equation 8.

In Equation 8, $S(t(y_0^i) = 1)$ denotes score of $t(y_0^i) = 1$ based on samples with lag order i. In this paper, it is argued that the trend features of samples are also important factors in the time series trend forecasting problem. Therefore, this paper argues that the score of $t(y_0^i) = 1$ when the lag order of samples is i is equal to the score calculated based on original features x_0^i plus the score calculated based on the trend features $t(x_0^i)$, as shown in Equation 7.

When the lag order of samples is i, $\Omega^i = \{x_j^i, j = 1, 2, ..., n - i - 1\}$ is naturally divided into different subsets $\Omega^i_l = \{x_j^i | \forall t(x_j^i) = t(x_h^i)\}$ based on the trend features of samples. And $\bigcup_l \Omega^i_l = \Omega^i$, $\forall k \neq l, \Omega^i_l \cap \Omega^i_k = \varnothing$.

Then, Ω_l^i are naturally partitioned into two different subsets $+\Omega_l^i = \{x_j^i | \forall t(x_j^i) = t(x_h^i), t(y_j^i) = 1\}, \ -\Omega_l^i = \{x_j^i | \forall t(x_j^i) = t(x_h^i), t(y_j^i) = -1\}, \ \text{depending on trend features of sample labels. And } +\Omega_l^i \cup -\Omega_l^i = \Omega_l^i, +\Omega_l^i \cap -\Omega_l^i = \varnothing.$

Therefore, based on the division of the above subsets, $S(t(y_0^i) = 1|x_0^i)$ and $S(t(y_0^i) = 1|t(x_0^i))$ are calculated using Equations 5, Equations 6 respectively.

In Equations 5 and 6, $U_{\Omega_l^i}(x_0^i)$ denotes the degree to which x_0^i is subordinate to Ω_l^i , which is the concept of degree of membership function in fuzzy sets. $U_{\Omega_l^i}(x_0^i) \in [0,1]$. $U_{\Omega_l^i}(x_0^i)$ is introduced to minimize the disturbance caused by random errors. For example, $\Omega_1^5 = \{x_j | t(x_j) = (1,1,-1,1)\}, \Omega_2^5 = \{x_j | t(x_j) = (1,1,1,1)\}, x = (15,16,17,16.9,18)$. Under the interference of random errors, x becomes $\hat{x} = (15,16,17,17.1,18)$. Apparently, $x \in \Omega_1^5$, but $\hat{x} \in \Omega_2^5$. Therefore, the subset to which the sample x belongs changes under the interference of random errors. So, in order to reduce the interference generated by random errors, $U_{\Omega_l^i}(x_0^i)$ is introduced in this paper. In this case, $U_{\Omega_1^5}(x) = 1, U_{\Omega_2^5}(x) = 0.75$ and $U_{\Omega_1^5}(\hat{x}) = 0.75, U_{\Omega_2^5}(x) = 1$. So, even though random interference makes x become \hat{x} , the introduction of $U_{\Omega_l^i}(x_0^i)$ makes \hat{x} still belong to a large extent to Ω_1^5 , the subset to which the real sample x belongs.

In Equations 3, $S(t(y_0^i)=1|x_0^i\in\Omega_l^i,t(x_0^i))$ denotes score of $t(y_0^i)=1$ computed based on $t(x_0^i)$ when $x_0^i\in\Omega_l^i$. Assuming that the sample size of Ω_l^i is 200, of which 100 samples belong to $+\Omega_l^i$, the frequency result of $S(t(y_0^i)=1|x_0^i\in\Omega_l^i,t(x_0^i))$ is 0.5. Assuming that the sample size of Ω_l^i is 60, of which 30 samples belong to $+\Omega_l^i$, the frequency result of $S(t(y_0^i)=1|x_0^i\in\Omega_l^i,t(x_0^i))$ is also 0.5. Nevertheless, we believe that the former result is more reliable because it is based on a larger sample size. Therefore, in this paper, we discard the pure frequency result to calculate $S(t(y_0^i)=1|x_0^i\in\Omega_l^i,t(x_0^i))$ and use Bayesian estimation to calculate it. Since the conjugate distribution of the binomial distribution is the beta distribution $\beta(a,b)$, in this paper we set the prior distribution to be $\beta(1,1)$. After calculation, the corresponding posterior distribution is $\beta(|+\Omega_l^i|+1,|-\Omega_l^i|+1)$. Therefore, $S(t(y_0^i)=1|x_0^i\in\Omega_l^i,t(x_0^i))=\frac{|+\Omega_l^i|+1}{|+\Omega_l^i|+|-\Omega_l^i|+2}$.

In Equations 4, $S(t(y_0^i) = 1 | x_0^i \in \Omega_l^i, x_0^i)$ denotes score of $t(y_0^i) = 1$ computed based on x_0^i when $x_0^i \in \Omega_l^i$. $S(t(y_0^i) = 1 | x_0^i \in \Omega_l^i, x_0^i)$ is defined as the Mahalanobis distance between x_0^i and $+\Omega_l^i$, and this Mahalanobis distance is mapped to [0, 1].

m is a threshold used to determine whether a sample set can be called a large sample set, which is usually equal to 50. when the sample size in Ω_l^i is smaller, the error generated by Equations 4 and 3 is larger, so, in this paper, we use conditional judgment to select the appropriate lag order i such that all the Ω_l^i corresponding to lag order i satisfy $|\Omega_l^i| > m$.

Therefore, the above description reveals that TeMoP has the following advantages:

- By integrating various models trained based on samples with different lag orders, TeMoP has excellent robustness.
- By introducing trend features, TeMoP has small prediction errors.

In the next section 4, an empirical analysis based on real-world data sets will be conducted to validate the above modeling merits.

4. Experiments

This section first provides a detailed description of the experimental data, assessment metrics, comparison models, experimental setup and experimental schemes. Then, the comparison results are fully analyzed.

4.1. Data description

There are nine major global financial market indices as data sets to assess models. In the experiment, the daily closing price of each index is selected for analysis. Table 3 provides the basic information of the selected stock index data sets. All data sets can be obtained from https://cn.investing.com/.

Table 3: Statistical summary for data sets

Data set	Abbreviation	Market type	Std^a	$LB(30)^b$	ADF^c	JB^d
Dow_Jones_Average	DJIA	Developed	5630.55	0.000^{e}	0.967^{e}	0.000^{e}
FTSE_China A50	FCA	Developing	3790.36	0.000	0.286	0.000
Hang_Seng	$_{ m HS}$	Semi-Developed	4693.36	0.000	0.164	0.000
NASDAQ_Composite	e NC	Developed	2235.40	0.000	0.999	0.000
Nifty_50	Nif	Developing	2986.29	0.000	0.916	0.000
$Nikkei_225$	Nik	Semi-Developed	4809.51	0.000	0.927	0.000
$S\&P_{-}500$	SP	Developed	653.28	0.000	0.988	0.000
Shanghai_Composite	SC	Developing	872.61	0.000	0.193	0.000
$SZSE_Component$	SZC	Developing	3518.29	0.000	0.170	0.000

^a Std denotes the standard deviation of data sets. ^b LB(30) denotes the Ljung-Box test for a series in the 30th order lag range. ^c ADF stands for ADF test (also called unit root test). ^d JB stands for Jarque-Bera test. ^e The significance level for all tests is 0.05.

According to the standard deviation, SP and SC exhibit lower volatility, while DJIA, HS, and Nik are the most volatile. Then, the p-value of the LB test rejects the original hypothesis that the data is white noise, indicating that all data sets hold significance for further analysis. Moreover, the p-value of the ADF test rejects the original hypothesis of no unit root in the data, implying that all data sets in our experiment are deemed non-stationary. Finally, the p-value results of the JB test, utilized to assess data adherence to a normal distribution, suggest that none of the data sets conform to a normal distribution.

In order to provide a comprehensive and objective assessment of models, the data sets are divided into four parts: a training set, two validation sets and a test set. The size of the training set is fixed at 3000. The size of every validation set is fixed at 300. The test set consists of 300 data points. Additionally, to prevent information leakage, there are time intervals between different sets. Figure 2 illustrates the division of different data sets.

Time series trend forecasting is often viewed as a binary classification problem. If the closing price of a stock at day t is higher than its closing price at day t-1, the stock movement trend is defined as "upward" $(y_t=1)$, otherwise as "downward" $(y_t=-1)$. Table 4 shows proportion of positive ("upward") samples in every data set. The results show that the proportions of positive ("upward") and negative ("downward") samples are very close to each other. Hence, the data sets are roughly balanced.

Table 4: Proportion of positive ("upward") samples in data sets

Data	Training	Validation1	Validation2	Test
DJIA	53.3%	50.5%	55.2%	56.5%
FCA	51.1%	56.9%	48.5%	54.5%
$_{\mathrm{HS}}$	52.2%	57.2%	53.5%	52.8%
NC	54.7%	58.2%	54.8%	59.9%
Nif	53.6%	54.8%	53.5%	56.5%
Nik	52.0%	52.5%	53.8%	51.2%
SP	54.8%	52.2%	53.8%	58.9%
SC	53.4%	57.2%	47.5%	53.2%
SZC	52.1%	52.5%	44.8%	56.2%

4.2. Evaluation metrics

In order to comprehensively assess prediction results, We adopt Accuracy (ACC), the area under the precision–recall curve (AUC), F1-score (F1) and

Figure 2: Division of data sets. The orange indicates training set. The black indicates time intervals. The green indicates validation set, and the red indicates test set.

Sharpe Ratio (SR), each of which measures a different aspect of the results.

Accuracy (ACC): ACC is used to calculate the percentage of samples that are correctly predicted out of all samples with predictions. The mathematical expression for ACC is shown in Equation 9, where TP is the true positive, TN is the true negative, FP is the false positive and FN is the false negative.

$$ACC = \frac{TP + TN}{TP + FP + TN + FN} \tag{9}$$

F1-score (F1): In contrast to ACC, F1 measures the performance of the model in positive and negative samples, respectively. F1 can evaluate the prediction performance of the model more comprehensively. The mathematical expression for F1 is shown in Equation 10.

$$F1 = \frac{2 \times PRE \times REC}{PRE + REC},\tag{10}$$

where

$$PRE = \frac{TP}{TP + FP},$$

$$REC = \frac{TP}{TP + FN}.$$

Sharpe Ratio (SR): SR is used to evaluate the investment performance of models in the real stock market. The larger the value, the higher the profitability of the model's forecast results. The mathematical expression for SR is shown in Equation 11.

$$SR = \frac{E(R_p) - R_f}{\sigma_p} \tag{11}$$

4.3. Models for comparison

The experiment selects several models from the fields of statistics, machine learning in narrow sense, and deep learning respectively for comparative analysis with TeMoP. Here is a short description of these models.

• Logistic Regression (LR): LR is a classical model used in statistical learning for classification tasks. The model has good interpretability.

- Support Vector Machines(SVM): SVM is a novel small-sample learning method with a solid theoretical foundation, strong generalization ability and easy interpretation of results.
- Random Forests (RF): RF is a classical model in the field of machine learning. Based on the bagging integration algorithm, RF has good robustness.
- Light Gradient Boosting Machine (LGBM): LGBM is also a classic model in the field of machine learning, based on the Boosting integration algorithm, LGBM has better prediction accuracy.
- Convolutional Neural Network (CNN): CNN, a foundational deep learning model, leverages convolution and pooling techniques to extract intricate features from input data efficiently.
- Long Short term Memory (LSTM): Unlike traditional feedforward neural networks, LSTM is recurrent, enabling it to capture long-term dependencies in sequence data.
- **ResCNN:** ResCNN (Zou et al., 2019), a state-of-the-art model, integrates residual network with convolutional neural network (CNN), for time series classification.
- InceptionTime: The emergence of InceptionTime (Ismail Fawaz et al., 2020) marks an important milestone in the field of time series classification. It not only reaches the level of accuracy of previous state-of-the-art methods, but also achieves a qualitative leap in scalability.

4.4. Experimental settings

The experiment is based on windows10 system. The programming language is Python3.8.1, and the corresponding compiler is PyCharm2020.1.2. The main Python libraries used in the experiment are numpy1.23.3, pandas1.4.4, tensorflow2.10.0, keras2.10.0, scikit-learn1.1.3, and tsai0.3.9.

4.5. Experimental schemes

Compared to the comparison models, TeMoP is not only a non-parametric model, but also can adaptively choose the maximum lag order according to

the nature of the data. Therefore, TeMoP only needs to be trained on Training and prediction performance is evaluated on Test based on different metrics. Therefore, for the fairness of the comparison between different models, two schemes are designed as follows. The hyper-parameter for comparison models is shown in Table 5.

- Scheme 1: For each data set, the lag order of samples used to train comparison models is consistent with the maximum lag order of TeMoP. Then, comparison models are trained on Training, and a set of optimal hyper-parameters is selected on Validation1 using the indicator F1 by grid search method. Finally, the prediction performance is evaluated on Test using different metrics.
- Scheme 2: Let the lag order $i \in [3,30]$. For each data set, each comparison model is trained on Training, and a set of optimal hyperparameters is selected on Validation1 using metric F1 by grid search method, and the optimal lag order is selected on Validation2 using metric F1. Finally, the predictive performance is evaluated on Test using different metrics. Since a large amount of literature (Zhao et al., 2022; Dudek, 2023) suggests that the number of lag orders generally does not exceed 30, and furthermore, since CNN is one of the comparison models and the hyper-parameter kernel_size in CNN generally takes a value of not less than 3, let the lag order i ∈ [3, 30].

The difference between Scheme 1 and 2 is that the former assigns lag orders to the comparison models, and the latter selects the optimal lag order based on the performance of different lag orders of the comparison models on the data sets.

4.6. Experimental results

4.6.1. Scheme 1

After training TeMoP on Training for each data set, the maximum lag order of TeMoP on data set SP is 5, and the maximum lag order on the other data sets is 6. Therefore, let the lag order of comparison models and the maximum lag order of TeMoP be the same on each data set. Then, each comparison model is trained on Training, and a set of optimal hyperparameters is selected on Validation1 using the indicator F1 by grid search method. Table 6 shows that optimal hyper-parameters for each model on different data sets.

Table 5: Hyper-parameter for comparison models

Model	Library	Hyper-paramete	Value

Finally, the prediction performance of all models is evaluated on Test using different metrics. Figure 3, 4, 5, 6 show ACC, AUC, F1, SR of models on different data sets for scheme 1 respectively. Table 7 shows the combined prediction performance of models on all data sets.

Figure 3: ACC of models on different data sets for scheme 1

In Figure 3, in addition to the data sets HS, Nik, TeMoP has the largest ACC on the remaining data sets. For the data set HS, compared to the largest ACC 0.558, ACC of TeMoP is 0.551, with a 1.2% difference. For data set Nik, compared to the largest ACC 0.510, ACC of TeMoP is 0.507, a difference of 0.6%. Therefore, for the data sets HS,Nik, the ACC of TeMoP is very close to the maximum ACC. This indicates that TeMoP performs very well on the metric ACC for each data set. In addition, among all the models, the ACC of just two models TeMoP and LGBM are greater than 0.5 on each data set, which indicates that TeMoP and LGBM have good robustness across data sets compared to the rest of the models. The mean

and standard deviation of the ACC results of all models on different data sets are shown in Table 7, which are used to measure the robustness of the models between different data sets. In Table 7, the mean ACC of TeMoP takes the largest value among all models. The standard deviation of ACC of TeMoP, LGBM, and LR is smaller compared to other models. Therefore, TeMoP exhibits the smallest prediction error and good robustness across data sets when measuring the prediction performance of the models based on the metric ACC.

Figure 4: F1 of models on different data sets for scheme 1

Unlike ACC, F1 allows a more objective assessment of the models' prediction accuracy. In Figure 4, TeMoP has the largest F1 on the rest of the data sets except for data set Nik. For data set Nik, compared to the largest F1 0.674, F1 of TeMoP is 0.637, a difference of 0.1%, which is very close to the largest F1. This indicates that the F1 of TeMoP is the largest in almost every data set. The consistent results between different data sets also reflect that QQ has good robustness. The mean and standard deviation of the F1 results of all models on different data sets are shown in Table 7. In Table 7,

the mean of F1 for TeMoP takes the largest value among all models. The standard deviation of F1 of TeMoP is smaller compared to other models. Therefore, TeMoP exhibits minimal prediction error and good robustness across different data sets when measuring the prediction performance of the model based on the metric F1.

Figure 5: AUC of models on different data sets for scheme 1

AUC measures the model's ranking ability. In Figure 5, AUC of TeMoP is more than 0.5 on all data sets except data sets Nik and SZC. TeMoP has the largest AUC in data sets SP and SC. TeMoP has the second largest AUC in data sets DJIA, FCA, NC, and Nif. The mean and standard deviation of the AUC results of all the models on different data sets are shown in Table 7. Table 7 shows that TeMoP has the largest mean AUC among all models, and the standard deviation AUC for TeMoP is smaller compared to the other models. Compared to the second largest mean AUC, mean AUC of TeMoP is 4 percentage points higher. Compared to the smallest average AUC, mean AUC improves by 10 percentage points. Therefore, TeMoP shows minimal prediction error and good robustness across data sets when measuring the

predictive performance of the model based on the metric AUC.

Figure 6: SR of models on different data sets for scheme 1

SR responds to the returns obtained by the portfolios based on the models' prediction results. In Figure 6, only TeMoP, SVM and LGBM have positive values on each data set, which indicates that the portfolios formed based on the prediction results of these models benefit on each stock index, reflecting the superiority and robustness of these models in simulating the returns. The mean and standard deviation of SR for all models on different data sets are shown in Table 7. In Table 7, although the mean SR of LR takes the largest value among all models, the standard deviation SR of LR is larger. In addition, LR has negative simulation returns on the data sets Nif and Nik. Therefore, taken together, TeMoP not only has a more superior mean SR, but also has a smaller standard deviation SR compared to other models. Therefore, when measuring the models' prediction performance based on the metric SR, TeMoP exhibits minimal prediction error and good robustness across different data sets.

Combining the performance of the models on different metrics, it can be

Table 7: Prediction performance of models for scheme 1

model	ACC	F1	AUC	SR
TeMoP	$0.562{\pm}0.030^a$	$0.716 {\pm} 0.024$	$0.527{\pm}0.027$	$0.037{\pm}0.018$
LR	$0.533 {\pm} 0.029$	0.616 ± 0.110	$0.511 {\pm} 0.041$	$0.040 {\pm} 0.057$
SVM	$0.550 {\pm} 0.041$	$0.640 {\pm} 0.219$	0.500 ± 0.001	0.034 ± 0.019
RF	$0.508 {\pm} 0.061$	$0.463{\pm}0.278$	$0.502 {\pm} 0.011$	0.010 ± 0.039
LGBM	$0.557 {\pm} 0.030$	$0.715 {\pm} 0.023$	$0.494{\pm}0.014$	$0.031 {\pm} 0.021$
CNN	$0.500 {\pm} 0.046$	$0.483 {\pm} 0.239$	$0.501 {\pm} 0.020$	-0.019 ± 0.058
LSTM	$0.483 {\pm} 0.055$	$0.324{\pm}0.266$	$0.505 {\pm} 0.041$	$0.006 {\pm} 0.034$
ResCNN	$0.508 {\pm} 0.066$	$0.476{\pm}0.328$	$0.483 {\pm} 0.043$	$0.020 {\pm} 0.035$
${\bf Inception Time}$	$0.477{\pm}0.660$	$0.322{\pm}0.335$	$0.495{\pm}0.039$	$0.018 {\pm} 0.035$

 $[^]a$ 0.562±0.030 denotes mean of this metric ± standard deviation of this metric between different data sets. b Bold indicates that this result is optimal for all models.

found that TeMoP shows superiority and robustness in terms of prediction accuracy, sequencing ability, and simulated returns compared to the comparison models. However, the comparative models are less robust, and the prediction accuracy, sorting ability, and simulated returns fluctuate greatly across different data sets. As a result, TeMoP has a better prediction performance compared to the comparison models.

4.6.2. Scheme 2

Let the lag order $i \in [3, 30]$. For each data set, each comparison model is trained on Training, and a set of optimal hyper-parameters is selected on Validation1 using metric F1 by grid search method, and the optimal lag orders are selected on Validation2 using metric F1. Table 8 shows that optimal hyper-parameters of the comparison models. Table 9 shows that optimal lag orders of the comparison models. Figure 7 shows F1 computed on Validation2.

First, RF, CNN, LSTM, ResCNN and InceptionTime all have F1 equal to 0 on certain data sets and certain lag orders, which suggests that the predictive ability of these models fails. Then, the predictive performance of these models varies greatly between data sets. In addition, the predictive performance of these models varies greatly between different lag orders on the same data set. This suggests that the robustness of these models is poor and is greatly affected by different data sets and different lag orders. Among all the compared models, LGBM has the optimal robustness. In Figure 7,

Table 8: Optimal hyper-parameters of comparison models for scheme 2

Model	Hyper-parameter	DJIA	FCA	HS	NC	Nif	Nik	SP	SC	SZC

the F1 of LGBM based on different lag orders are very concentrated in the same data set. The F1 of LGBM are also more stable between different data sets.

Figure 7: F1 computed on Validation2

Finally, the predictive performance of all models based on this set of hyper-parameters and these lag orders is evaluated on Test using different metrics. Figure 8, 9, 10, 11 show ACC, AUC, F1, SR of models on different data sets for scheme 2 respectively. Table 10 shows the combined prediction performance of models on all data sets.

In Figure 8, TeMoP has the largest ACC on the remaining data sets except for data set NC, SP. There is a 1.5% difference for the ACC of TeMoP 0.599 compared to the maximum ACC 0.608 on data set NC. On data set SP, compared to the maximum ACC 0.604, the ACC of TeMoP 0.593 differs by 1.8%. The calculations in Table 10 show that not only does TeMoP still have the largest mean ACC 0.562, but TeMoP also has the smallest standard deviation ACC 0.030. Therefore, for scheme 2, TeMoP exhibits the smallest prediction error and the best robustness across different data sets when measuring the prediction performance of the model based on the metric ACC.

Figure 8: ACC of models on different data sets for scheme 2

Figure 9: F1 of models on different data sets for scheme 2 $\,$

Further, Figure 9 shows the F1 scores of the different models. Unlike the case in Scheme 1 where the F1 of the models appeared to be equal to 0, in Figure 9, the F1 of each model is much larger than 0, which indicates that the models trained according to Scheme 2 have better prediction accuracy and improved robustness compared to Scheme 1. Although the F1 scores of all models are very close, TeMoP is still the best performing model among all models. As can be seen from Table 10, it has the largest mean 0.716 and the smallest standard deviation 0.024.

Figure 10: AUC of models on different data sets for scheme 2

In terms of the ranking ability of models, except for TeMoP and LR, AUC of the rest of the models is around 0.5 in Figure 10, which reflects the poor ranking ability of these models. Except for SZC and Nik, AUC of TeMoP on the rest of the data sets takes values significantly greater than 0.5. In Table 10, Combining all the data sets, TeMoP has the largest mean 0.527 and smaller standard deviation 0.027, which demonstrates the superiority and robustness of TeMoP in terms of model ranking ability.

In terms of simulated returns, although all models take positive values

Figure 11: SR of models on different data sets for scheme $2\,$

on mean as shown in Table 10, only the LGBM and TeMoP take SR values greater than 0 on all data sets as shown in Figure 11, reflecting the superiority and robustness of the LGBM and TeMoP in terms of simulated returns. Among all models, TeMoP has the largest mean SR 0.037 and the smallest standard deviation 0.018, which TeMoP demonstrates superiority and robustness in simulating returns compared to other models.

Table 10: Prediction performance of models for scheme 2

model	ACC	F1	AUC	SR
TeMoP	$0.562 {\pm} 0.030^{a}$	$0.716{\pm}0.024$	$0.527 {\pm} 0.027$	$0.037{\pm}0.018$
LR	$0.547 {\pm} 0.038$	$0.686 {\pm} 0.041$	0.512 ± 0.034	0.017 ± 0.039
SVM	$0.548 {\pm} 0.039$	$0.664 {\pm} 0.153$	0.500 ± 0.001	$0.030 {\pm} 0.023$
RF	$0.543 {\pm} 0.041$	$0.682 {\pm} 0.066$	$0.496{\pm}0.008$	$0.015 {\pm} 0.024$

 $[^]a$ 0.562±0.030 denotes mean of this metric ± standard deviation of this metric between different data sets. b Bold indicates that this result is optimal for all models.

Combining the results of all the data sets we find that similar to Scheme 1, TeMoP shows significant superiority and robustness in terms of prediction accuracy, model ranking ability, and simulated returns. In addition, we also find that the way in which the lag order is chosen as a hyper-parameter based on the models' performance on the data sets has more robust results compared to the way in which it is specified directly.

5. Summary and Outlook

Based on the unsatisfactory performance of existing models in dealing with time series trend problems, this paper designs a novel multiple lag order probabilistic model based on trend encoding TeMoP. Traditional forecasting models often use samples of a certain lag order for training and forecasting. However, this approach tends to make the prediction model poorly robust on different data sets, or on different time periods of the same data set. Therefore, from the design principle, TeMoP discards this approach.

TeMoP adaptively calculates the maximum lag order based on the nature of data. Then, for each lag order i that does not exceed the maximum lag order, it obtains a sample set Ω_i , and trains a model based on Ω_i . Finally, the calculation results of each model are considered comprehensively in order to improve robustness on different data sets. In addition, TeMoP introduces trend features to improve the predictive accuracy.

In order to comprehensively analyze the forecasting performance of TeMoP on realistic data sets, a total of nine stock index data sets from three different market types are selected for the experiment. There are three data sets from developed markets, two data sets from semi-developed markets and four data sets from developing markets. Meanwhile, the experiment selects a total of six classical models from three different domains, namely statistics, narrow machine learning, and deep learning, for comparative analysis with TeMoP. In addition, two state-of-the-art models are added to the experiment to compare the advantages and disadvantages between TeMoP and state-of-the-art models.

Unlike the comparison models, TeMoP not only can adaptively select the maximum lag order, but also is a non-parametric model. Therefore, TeMoP avoids the step of choosing the optimal hyper-parameters. Therefore, in order to enhance the fairness of the comparison between different models, two comparison schemes are designed in the experiment. Scheme 1 specifies the lag order, and Scheme 2 treats the lag order as a hyper-parameter of models chosen based on models' performance on data.

Combining the experimental results of Scheme 1 and 2, we find that:

- TeMoP shows significant superiority compared to the comparison models, both in terms of prediction accuracy, model ordering ability and simulation gains based on model prediction results. At the same time, this superiority shows good robustness across different data sets.
- The predictive performance of the comparison model fluctuates greatly between different data sets, and also fluctuates greatly between different lag orders. This indicates that the robustness of the comparison model is poor.

This study mainly analyzes the prediction of the next trend of TeMoP. However, in practical applications, the prediction of n steps under time series data is also of great significance. Therefore, the future work will focus on

the model performance of TeMoP in the next n step prediction to enhance the practical application significance.
