We investigate tensor condensates and chiral condensates in the (2+1)-flavor Nambu-Jona-Lasinio model at finite temperature and density in the presence of a strong magnetic field. The emergence of the tensor condensate is attributed to the four-fermion interaction. It is shown that a sufficiently large chemical potential is necessary for the occurrence of a phase transition towards tensor condensate. Furthermore, we investigate the correlation between tensor condensate and spin polarization, which accounts for the oscillatory behavior of the spin polarization during the transition from the chiral condensate to tensor condensate phase.

I. INTRODUCTION

As our understanding of matter has deepened, the investigation of the phase diagram of strong interactions has emerged as a fundamental and crucial topic. The behavior of Quantum Chromodynamics (QCD) matter in magnetic fields contributes to our understanding of nuclear matter under extreme conditions, such as early universe evolution [1], Relativistic Heavy Ion Collider experiments [2, 3], neutron stars [4], and compact stars [5, 6]. Additionally, the spin polarization of quark matter could be pertinent to various astrophysical phenomena, such as neutron stars [7], spontaneous polarization of quark matter [8], and vacuum polarization with ferromagnetism [9–11]. In theoretical research, first-principles calculations, particularly lattice Quantum Chromodynamics (LQCD), offer reliable predictions of QCD phase properties and transitions at zero baryon chemical potential and finite temperature [12]. These predictions serve as a valuable reference in confirming the chiral phase transitions and spin-polarization phase transitions under magnetic fields. In Relativistic Heavy Ion Collider (RHIC) experiment, a magnetic field as intense as $10^{15}G$ was observed [3]. Neutron stars are known to have strong magnetic fields on their surface and in the core [4, 13]. It is noted that in neutron stars with intense magnetic fields, one fascinating phenomenon is the occurrence of stable pulses and the emergence of multiple magnetic poles [14]. Therefore, our focus is on the spin polarization of QCD matter and the provide explanations for these phenomena.

In the study of spin polarization, the Nambu-Jona-Lasinio(NJL) model can be employed by including the four-fermion interaction. In the relativistic limit, the expression of spin polarization is consistent with that given by the four-fermion interaction [15, 16]. The introduction of a strong magnetic field in the magnetic NJL(MNJL) model presents us with a multitude of new challenges [17–20]. First, a strong magnetic field will cause energy level splitting for charged particles. Second, the spin of particles will precess in an external magnetic field.

In 1976, 't Hooft introduced quantum effects involving four-dimensional pseudoscalar interactions, which were fundamental in subsequent studies on spin polarization [21]. In the 1900s, the relativistic framework was considered more suitable for investigating spin polarization, which was implicitly defined through the spin polarization operator [22, 23]. Subsequently, it was revealed that the final outcome of Lagrangian for spinors, as calculated by 't Hooft in Ref [21, 24]. In 2000, Toshitaka investigated the ferromagnetism of quark fluid and demonstrated that quark matter could form a ferromagnetic phase due to single gluon exchange interactions, which exhibits a so-called spin flip effect [25]. Since 2012, the spin-polarized phase has gained much attention due to the separation of the axial vector term and tensor term in the framework of quark meson model. Bohr found an anomalous magnetic moment phenomenon within the axial vector [24]. In 2017, Maruyama suggested that spin polarization results from the contribution of tensor interactions, thereby diminishing the influence of the axial vector [8]. In 2020, Kagawa incorporated the hexaquark interaction, challenging previous conclusions regarding tensor interaction terms [26]. Recently, Qiu and Feng delved into the comparison of anomalous magnetic moments with spin polarization under strong magnetic fields, which offered a method to account for the inverse magnetic catalysis [27]. Additionally the deconfined phase with restored chiral symmetry also had been studied [28]. It is interesting that quarkyonic phase could be affected by TSP. Furthermore it had been observed that the Gell-Mann-Oakes-Renner relation breaks down when considering AMM or TSP effect [29].

This work is organized as follows: In Sec.II, we present the thermodynamics involving chiral and tensor condensate in a strong magnetic field. In Sec.III, the numerical result is shown for the phase of tensor condensate, quark chiral condensate, and spin polarization at finite temperature and chemical potential. A summary and short conclusion are presented in Sec.IV.

II. THE (2+1)-FLAVORS NJL MODEL UNDER A MAGNETIC FIELD

We consider the following generalized Lagrangian density of the (2+1)-flavors NJL model in a strong magnetic field [21, 30],

$$\mathcal{L} = \mathcal{L}_0 + \mathcal{L}_S + \mathcal{L}_T + \mathcal{L}_I - \frac{1}{4} F_{\mu\nu} F^{\mu\nu}, \tag{1}$$

$$\mathcal{L}_0 = \bar{\psi}(i\gamma^{\mu}\mathcal{D}_{\mu} - \hat{m}_0)\psi,\tag{2}$$

$$\mathcal{L}_S = G_s \sum_{a=0}^{8} \left[(\bar{\psi}\lambda_a \psi)^2 + (\bar{\psi}i\gamma^5 \lambda_a \psi)^2 \right], \tag{3}$$

$$\mathcal{L}_T = G_t \sum_{a=0}^{8} \left[(\bar{\psi} \Sigma_3 \lambda_a \psi)^2 + (\bar{\psi} \Sigma_3 i \gamma^5 \lambda_a \psi)^2 \right], \tag{4}$$

$$\mathcal{L}_I = G_k[\det \bar{\psi}(1+\gamma_5)\psi + \det \bar{\psi}(1-\gamma_5)\psi], \tag{5}$$

where \mathcal{L}_I is Kobayashi-Maskawa't Hooft term or the determinant interaction term, which leads to the six-point interaction between quarks in the three-flavor case. \mathcal{L}_T is closely related to the spin-spin interaction, which causes spin-polarization condensate. \mathcal{L}_S is four-point tensor interaction between quarks in the three-flavor case, which preserves chiral symmetry [7, 31, 32]. $\psi = (u, d, s)^{\top}$ is three-flavor quark field, and the diagonal current quark mass matrix is $\hat{m}_0 = \operatorname{diag}_f(m_u, m_d, m_s)$. We adapt color indices c = (r, b, g) and flavor indices f = (u, d, s). λ_a , $(a = 1, ..., N_f^2 - 1)$

are the flavor SU(3) groups of generators, also known as the Gell-Mann matrix. $\Sigma_3 = \begin{bmatrix} \sigma_z & 0 \\ 0 & -\sigma_z \end{bmatrix}$ is spin project operator, and related to the Dirac matrix by $\gamma^1 \gamma^2 = i \Sigma_3$.

The significant disparity in masses between the s quark and the u, d quarks gives rise to a violation of the SU(3) symmetry. The covariant derivative is defined as $\mathcal{D}_{\mu} = \partial_{\mu} + iQA_{\mu}^{ext}$, with the quark charge matrix, $Q = diag(q_u, q_d, q_s) = diag(\frac{2}{3}, -\frac{1}{3}, -\frac{1}{3})$, and $A_{\mu}^{ext} = (0, 0, Bx, 0)$ is the gauge field with the constant magnetic field should point at the z-direction [27, 33]. In this paper, we adopt the mean-field calculation scheme. The chiral term arises from the four-fermion interaction. In the three-flavor context, a novel interaction term appears, as a six-point interaction. The tensor term characterizes the tensor component of the spin polarization, assuming a spin polarization direction along the z-axis.

In this context, the quark-antiquark condensates are denoted as $\phi_f = \langle \bar{\psi}\psi \rangle$, and the spin polarization condensates, denoted as $F_a = -G_t \langle \bar{\psi} \Sigma_z \lambda_a \psi \rangle$. If the spin polarization parameter is defined as $\kappa_S = \frac{\rho_{\uparrow} - \rho_{\downarrow}}{\rho_{\uparrow} + \rho_{\downarrow}}$, it can be related to F_a through a Lorentz transformation [9, 24, 25]. This suggests that the four-fermion interaction derived by 't Hooft can effectively account for spin polarization. In the case of (2+1) flavors of quarks, the Gell-Mann matrix enables the expression of $F_3 = -G_t \langle \bar{\psi} \Sigma_z \lambda_3 \psi \rangle$ and $F_8 = -G_t \langle \bar{\psi} \Sigma_z \lambda_8 \psi \rangle$ from F_a . It is important to note that F_3 and F_8 do not directly represent spin-up or spin-down states, but rather the clustering of quark matter in flavor space. Additionally, the signs of the F_3 and F_8 may depend on the chosen representation. In this paper, we have chosen the chiral Weyl representation. Meanwhile, we can transform the spin polarization term into a tensor condensate as follow [24, 26],

$$F_u = F_3 + \frac{1}{\sqrt{3}} F_8, \tag{6}$$

$$F_d = -F_3 + \frac{1}{\sqrt{3}}F_8,\tag{7}$$

$$F_s = -\frac{2}{\sqrt{3}}F_8.$$
 (8)

To obtain the case in the magnetic field, we use the following substitution, from the Landau level and the dispersion relation for the quark [34], $p_0 \to i(\omega_{\nu} - i\mu_f)$, $\mathbf{p}^2 \to p_z^2 + (2n+1-\eta)$, where the spin quantum number is $\eta = \pm 1$, and the landau quantum number n = 0, 1, 2... The integral should be changed as $\frac{1}{(2\pi)^4} \int d^4 \mathbf{p} \to \frac{Tq_f B_m}{(2\pi)^2} \sum_{\nu=\pm} \sum_{n=0}^{\infty} \int dp_z$. In the above relationship, we use $\omega_{\nu} = (2\nu + 1)\pi T$ to represent the Matsubara frequencies. Following the standard scheme [27], the single-particle energy in the presence of a magnetic field can be expressed as,

$$E_{f,k,\eta} = \sqrt{p_z^2 + (\sqrt{M_f^2 + 2k|q_f B|} + \eta F_f)^2},$$
(9)

where M_f is the effective mass of quark, F_f is the quark of tensor condensates, q_f is quark electric charge, and $k = 2n + 1 - \eta$ is the quantum number of Landau level, p_z is the momentum in the z-direction. The grand canonical ensemble thermodynamic potential with the chiral and spin polarization condensate is given by [25],

$$\Omega(T, \mu, M_u, M_d, M_s, F_3, F_8) = -\frac{N_c}{4\pi^2} \sum_{k=0}^{\infty} \sum_{f=u, \eta=\pm}^{d,s} \sum_{\eta=\pm} |q_f B| \int dp_z \left\{ E_{f,k=0} + E_{f,k,\eta} + T \ln\left[1 + \exp\left(-\frac{E_{f,k,\eta} - \mu}{T}\right)\right] + T \ln\left[1 + \exp\left(-\frac{E_{f,k,\eta} + \mu}{T}\right)\right] \right\} + \sum_{f=u}^{d,s} 2G_s \phi_f^2 + \frac{F_3^2 + F_8^2}{2G_t} + 4G_k \phi_u \phi_d \phi_s, \tag{10}$$

where $N_c = 3$ is the number of colors, μ is chemical potential. And we assume all chemical potentials to be equal for simplifying our calculations, T is temperature. Finally, we can formulate the mean-field Lagrangian in a strong magnetic field [18],

$$\mathcal{L} = \bar{\psi}(iD_{\mu}\gamma^{\mu} - \hat{M} - F_{3}\Sigma_{3}\lambda_{3} - F_{8}\Sigma_{8}\lambda_{8})\psi - 2G_{s}(\phi_{u}^{2} + \phi_{d}^{2} + \phi_{s}^{2}) + 4G_{k}\phi_{u}\phi_{d}\phi_{s} - \frac{F_{3}^{2}}{2G_{t}} - \frac{F_{8}^{2}}{2G_{t}},\tag{11}$$

where $\hat{M} = \text{diag}(M_u, M_d, M_s)$, and M_f is the effective quark mass. In preceding calculations, we ignored the electromagnetic interaction terms $\mathcal{L}_M = -\frac{1}{4}F_{\mu\nu}F^{\mu\nu}$, as would not contribute to a normalized thermodynamic potential $\Omega_{eff} = \Omega - \Omega_0$, where Ω_0 represents the vacuum contribution.

By minimizing thermodynamic potential of the system, we can have the gap equations.

$$\frac{\partial \Omega}{\partial \phi_f} = \frac{\partial \Omega}{\partial F_3} = \frac{\partial \Omega}{\partial F_8} = 0. \tag{12}$$

One can also formulate the Fermi distribution function of quarks,

$$N_{f,k,\eta}^{\pm} = \frac{1}{1 + \exp\left[\frac{E_{f,k,\eta} \mp \mu}{T}\right]},\tag{13}$$

and give rise to the net density of quarks,

$$\rho_f = \sum_{k=0}^{\infty} \alpha_k \frac{N_c |q_f B|}{4\pi^2} \int dp (N_{f,k,\eta}^+ - N_{f,k,\eta}^-), \tag{14}$$

where the degeneracy is $\alpha_k = \delta_{0,k} + \Delta(k) \sum_{\eta=\pm}$, if k = 0, then $\Delta(0) = 0$, else $\Delta(k) = 1$. By solving the gap equations, we can determine the effective quark mass,

$$M_u = m_u - 4G_s\phi_u + 2G_k\phi_d\phi_s,\tag{15}$$

$$M_d = m_d - 4G_s\phi_d + 2G_k\phi_u\phi_s,\tag{16}$$

$$M_s = m_s - 4G_s\phi_s + 2G_k\phi_d\phi_u, \tag{17}$$

where m_f is quark current mass. For the purpose of convenience, the thermodynamic potential is divided into a free part and an interacting part. Due to the divergence caused by vacuum contribution, a sharp cutoff Λ is employed to guarantee the convergence of the integral. Hence, the total thermodynamic potential is a sum of following three terms,

$$\Omega_f = \Omega_f^{vac} + \Omega_f^{med} + \Omega^{Int}, \tag{18}$$

$$\Omega_f^{vac} = -\frac{N_c |q_f B|}{4\pi^2} \int_{\Lambda_z} dp_z \left[\sum_{k=0}^{k_{max}^{mag}} E_{f,k}^+ + \sum_{k=1}^{k_{max}^{mag}} E_{f,k}^- \right] \Theta(p_\perp^2) \Theta(\Lambda^2 - p_\perp^2), \tag{19}$$

$$\Omega_f^{med} = -\frac{N_c |q_f B|}{4\pi^2} \int dp_3 \left\{ \sum_{k=0}^{k_{max}^{\mu}} \left[T \ln \left[1 + \exp(-\frac{E_{f,k}^+ - \mu}{T}) \right] + T \ln \left[1 + \exp(-\frac{E_{f,k}^+ + \mu}{T}) \right] + \sum_{k=1}^{k_{max}^{\mu}} \left[T \ln \left[1 + \exp(-\frac{E_{f,k}^- - \mu}{T}) \right] + T \ln \left[1 + \exp(-\frac{E_{f,k}^- + \mu}{T}) \right] \right] \right\}, \tag{20}$$

$$\Omega_f^{Int} = \sum_{f=u}^{d,s} 2G_s \phi_f^2 + \frac{F_3^2 + F_8^2}{2G_t} - 4G_k \phi_u \phi_d \phi_s, \tag{21}$$

where Ω_f^{vac} is the quark condensate vacuum dependent on the magnetic field, and Θ is Heaviside step function. In the view of non-renormalization of the NJL model [35], the regularization has also been suggested [36, 38]. The other parameters are $p_{\perp}^2 = (\sqrt{M_f^2 + 2k|q_fB_m|} + F_f)^2 - M_f^2$, and the Landau levels can be written as,

$$\Lambda_{z}^{2} = \Lambda^{2} - (2k|q_{f}B_{m}| - 2M_{f}F_{f} + 2\eta F_{f}\sqrt{M_{f}^{2} + 2k|q_{f}B_{m}|})$$

$$k_{max}^{\pm} = \text{Floor}\left[\frac{(\Lambda \mp F_{f})^{2} - M_{f}^{2}}{2|q_{f}B|}\right]$$
(22)

If F_3 approaches the limit 0, the eq.(19) can be reduced to the form given in Ref [18]. The entropy of quark also can be written as $S_f = -\frac{\partial \Omega_f}{\partial T}$,

$$S_{f} = -\frac{N_{c}|q_{f}B|}{4\pi^{2}} \int dp_{z} \left\{ \sum_{k=0}^{\mu_{max}} \left[N_{f,k,\eta=+1}^{+} \ln[N_{f,k,\eta=+1}^{+}] + (1 - N_{f,k,\eta=+1}^{+}) \ln(1 - N_{f,k,\eta=+1}^{+}) + \left[N_{f,k,\eta=+1}^{+} \leftrightarrow N_{f,k,\eta=+1}^{-} \right] \right] + \sum_{k=1}^{\mu_{max}^{+}} \left[N_{f,k,\eta=-1}^{+} \ln[N_{f,k,\eta=-1}^{+}] + (1 - N_{f,k,\eta=-1}^{+}) \ln(1 - N_{f,k,\eta=-1}^{+}) + \left[N_{f,k,\eta=-1}^{+} \leftrightarrow N_{f,k,\eta=-1}^{-} \right] \right] \right\},$$

$$(23)$$

Correspondingly, the corresponding chiral condensate is a sum of two terms as $\phi_f = \phi_f^{vac} + \phi_f^{med}$,

$$\phi_f^{vac} = -\frac{N_c |q_f B|}{4\pi^2} \int_{\Lambda_z} dp_z \Big[\sum_{k=0}^{k_{max}} \frac{M_f(\sqrt{M_f^2 + 2k|q_f B_m|} + F_f)}{E_{f,k}^+ \sqrt{M_f^2 + 2k|q_f B_m|}} + \sum_{k=1}^{k_{max}} \frac{M_f(\sqrt{M_f^2 + 2k|q_f B_m|} - F_f)}{E_{f,k}^- \sqrt{M_f^2 + 2k|q_f B_m|}} \Big], \tag{24}$$

$$\phi_f^{med} = \frac{N_c |q_f B|}{4\pi^2} \int \mathrm{d}p_z \left\{ \sum_{k=0}^{k_{max}^{\mu}} \frac{M_f(\sqrt{M_f^2 + 2k|q_f B|} + F_f)}{E_{f,k}^+ \sqrt{M_f^2 + 2k|q_f B|}} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ + \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \left[\frac{1}{1 +$$

$$\sum_{k=1}^{k_{max}^{\mu}} \frac{M_f(\sqrt{M_f^2 + 2k|q_f B|} - F_f)}{E_{f,k}^{-}\sqrt{M_f^2 + 2k|q_f B|}} \Big[\frac{1}{1 + \exp(\frac{E_{f,k}^{-} - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^{-} + \mu}{T})} \Big] \Big\}, \tag{25}$$

and the spin polarization condensate is also a sum of two terms $FFt_f = FFt_f^{vac} + FFt_f^{med}$,

$$FFt_f^{vac} = -\frac{N_c|q_f B|}{4\pi^2} \int_{\Lambda_z} dp_3 \Big[\sum_{k=0}^{k_{max}} \frac{\sqrt{M_f^2 + 2k|q_f B_m|} + F_f}{E_{f,k}^+} - \sum_{k=1}^{k_{max}} \frac{\sqrt{M_f^2 + 2k|q_f B_m|} - F_f}{E_{f,k}^-} \Big], \tag{26}$$

$$FFt_f^{med} = \frac{N_c|q_fB|}{4\pi^2} \int dp_3 \left\{ \sum_{k=0}^{k_{max}^{\mu}} \frac{\sqrt{M_f^2 + 2k|q_fB|} + F_f}{E_{f,k}^+} \left[\frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ + \mu}{T})} \right] - \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} \right] - \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} = \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^+ - \mu}{T})} = \frac{1}{$$

$$\sum_{k=1}^{k_{max}^{\mu}} \frac{\sqrt{M_f^2 + 2k|q_f B|} - F_f}{E_{f,k}^-} \Big[\frac{1}{1 + \exp(\frac{E_{f,k}^- - \mu}{T})} + \frac{1}{1 + \exp(\frac{E_{f,k}^- + \mu}{T})} \Big] \Big\}, \tag{27}$$

from the relations $\frac{\partial \Omega_f}{\partial F_3} = \frac{\partial \Omega_f}{\partial F_f} \frac{\partial F_f}{\partial F_3}$ and $\frac{\partial \Omega_f}{\partial F_8} = \frac{\partial \Omega_f}{\partial F_f} \frac{\partial F_f}{\partial F_8}$ in eq.(12). Then, the following terms could be obtained,

$$F_3 = G_t(FFt_u - FFt_d), \tag{28}$$

$$F_8 = \frac{G_t}{\sqrt{3}}(FFt_u + FFt_d - 2FFt_s). \tag{29}$$

Gap equations may have multiple solutions, but the solution with the lowest thermodynamic potential is considered as the physically solution.

III. NUMERICAL RESULTS AND DISCUSSIONS

For simplifying calculations, we adopt the coupling constants as $\Lambda^2 G_s = 1.835$, $G_t = 2G_s$, $\Lambda^5 G_k = 9.29$, and a sharp cutoff $\Lambda = 631.4$ MeV [36, 39]. Quark current masses $m_u = m_d = 5.6$ MeV, $m_s = 135.7$ MeV is used to produce the empirical values $f_{\pi} = 91$ MeV, $m_{\pi} = 138$ MeV, $m_K = 495.7$ MeV, $m_{\eta'} = 957.5$ MeV.

A. Condensate Versus Temperature

FIG. 1 illustrates the effective mass of u quark and s quark as functions of increasing temperature at a chemical potential $\mu=150$ MeV. The light quark mass M_u exhibits a apparent drop in the low-temperature region, which indicates partial restoration of chiral symmetry. At the magnetic field $eB=0.20~{\rm GeV^2}$, the spin polarization is enhanced, and results in a partial restoration of chiral symmetry as the temperature increases. The changes in magnetic field have weak effect on the transition temperature of chiral transitions at the temperature larger than $T=140~{\rm MeV}$. Quark matter characterized by tensor condensation displays a magnetic catalytic effect, which is available without the tensor condensation [41–43].

FIG. 1: The temperature dependence of the effective masses (M_u and M_s) for u and s quarks is shown under four different magnetic fields. The effective masses of u and s quarks are marked by the dotted and solid lines respectively. The various colored lines indicate different magnetic fields: red for $eB = 0.05 \text{ GeV}^2$, blue for $eB = 0.10 \text{ GeV}^2$, green for $eB = 0.15 \text{ GeV}^2$, and brown for $eB = 0.20 \text{ GeV}^2$

Almost horizontal line are observed for the u and s quarks in FIG. 2, at magnetic field below $eB = 0.20 \text{ GeV}^2$. F_3 can be considered as a measure of the tensor condensate, defined as $F_3 = \rho(\uparrow) - \rho(\downarrow)$, which represents the relative mismatch between spin-up and spin-down states densities. Moreover, the absence of F_3 for the s quark can be attributed to mathematical calculations involving Gell-Mann matrices. It is concluded that s quarks may exhibit arbitrary spinning directions. In fact, at the low chemical potential and temperature, a tensor condensate transition of quarks is difficult to occur.

FIG. 2: The temperature dependences of the tensor condensation is temperature-dependent for four different magnetic fields, as shown in Panels A $(eB = 0.05 \text{ GeV}^2)$, B $(eB = 0.10 \text{ GeV}^2)$, C $(eB = 0.15 \text{ GeV}^2)$, and D $(eB = 0.20 \text{ GeV}^2)$. The red, green, and blue lines denote u, d and s quarks respectively.

FIG. 3: Comparison of tensor condensation and spin polarization at chemical potentials $\mu = 150$ MeV (A, C) and $\mu = 500$ MeV (B, D) in a magnetic field eB = 0.10 GeV². In Panels A and B, the color red represents the u quark, blue represents the d quark, and green represents the s quark. In Panels C and D, purple corresponds to F_3 , while cyan corresponds to F_8 .

The different chemical potentials of tensor condensation are illustrated in FIG. 3. Comparing panels (A) and (B), it can be observed that tensor condensation leads to a crossover transition as the temperature increases. In FIG.3 panel D, the F_8 exhibits a monotone decrease, while F_3 shows fluctuations. At a high chemical potential $\mu = 500$ MeV and low temperature T = 50 MeV, there are significant constraints that render the quark spin aligns with the direction of the magnetic field. As the temperature increases, the thermal motion of quark disrupts the states, which is indicated by the fluctuation of F_3 . As for F_8 , its behavior resembles that of ferromagnetic. However, tensor condensation

does not exist in the region of low temperature and low chemical potential due to the minimal constraints on spin polarization.

B. Condensate Versus Chemical Potential

The effective mass of the u and s quarks at four different magnetic fields are depicted as functions of chemical potentials at the temperature $T=50 \,\mathrm{MeV}$ in FIG. 4. It is observed that the first-order chiral restoration occurs with an increase in the magnetic field. This can be explained by the appearance of quark tensor condensates. Particularly, at a weak magnetic field $eB=0.05 \,\mathrm{GeV^2}$, there is a partial restoration of quark chiral symmetry, which signals a crossover process. At high temperature the effective mass is unequal to current mass in the region of tensor condensation. This discrepancy is attributed to the energy gaining from spin polarization, which compensates for the loss of energy caused by the reduction in the chiral condensate.

The tensor condensates at four different magnetic fields is depicted in FIG. 5 at the temperature $T=50~{\rm MeV}$. It is evident that, except for a magnetic field of $eB=0.05~{\rm GeV}^2$ with a crossover process, the tensor condensation demonstrates a first-order transition process at all other magnetic fields. Furthermore, it can be observed that as the magnetic field increases, the crossover region gradually shortens and eventually turns into a first-order transition. In contrast to the chiral condensate shown in FIG. 4, the critical chemical potential $\mu=310~{\rm MeV}$ for the tensor condensation remains relatively unaffected by the magnitude of the magnetic field. This result is consistent with previous studies [37].

FIG. 4: The dependence of the effective masses of u and s quarks on the chemical potential is shown under four different magnetic fields. The dotted line represents the effective mass of the u quark, while the solid line represents the effective mass of the s quark. The colored lines correspond to different magnetic fields: red for $eB = 0.05 \text{ GeV}^2$, blue for $eB = 0.10 \text{ GeV}^2$, green for $eB = 0.15 \text{ GeV}^2$, and brown for $eB = 0.20 \text{ GeV}^2$.

In FIG.6, the behaviors of F_3 and F_8 under different magnetic field strengths are shown at T=50 MeV. It is evident that F_3 is significantly enhanced by the magnetic field at the chemical potential below the critical value $\mu=340$ MeV. As the chemical potential continues to increase, the growth rate of F_3 at eB=0.10 GeV² is faster than the case of eB=0.05 GeV². In the right panel, F_8 exhibits a significant increase until it reaches a peak. Further increase of the chemical potential will result in a decrease in F_8 . This behavior can be interpreted as the onset of quark ferromagnetism occurring at the critical chemical potential. Subsequently, the quark spin aligns with the magnetic field directions. The ferromagnetic properties of quark matter can be accounted for by the phenomenon of tensor condensation in quark matter. The result at eB=0 from Ref [31] is marked by the black solid line for comparison. It is found that the behavior at weak magnetic field is close to the result of [31] The presence of an external magnetic field enhances spin polarization and makes it appear in a larger value at lower chemical potential by comparison with the zero magnetic field.

At the larger chemical potential, quarks would generally be in Cooper pairs leading to color superconductivity. It is possible that the tensor condensate diminishes with the formation of bosons, and the spin anti-parallel pairs could lead to the fluctuation of F_3 .

Fig.7 shows the number of the Landau energy levels of u, d and s quarks at different magnetic fields. With the increase of magnetic fields, Landau energy level decreases. As quarks from the tensor condensate, the Landau energy level increases. The number of $\eta = 1$ energy levels of light quarks is higher than the number of $\eta = -1$ energy levels

FIG. 5: The dependence of quark tensor condensation on the chemical potential is shown for four different magnetic fields. In Panels A, B, and C, are for the u, d, and s quarks respectively.

FIG. 6: The dependence of quark SP $(F_3$ and $F_8)$ on chemical potential (μ) is investigated for four different magnetic fields. In Panel A, F_3 is shown, and in Panel B, F_8 is shown at different magnetic fields red for $eB=0.05~{\rm GeV^2}$, blue for $eB=0.10~{\rm GeV^2}$, green for $eB=0.15~{\rm GeV^2}$, and brown for $eB=0.20~{\rm GeV^2}$, and black for $eB=0.00~{\rm GeV^2}$, represented by colored lines from bottom to top.

in tensor condensate. It means that the effect of spin polarization is mainly reflected in the Landau energy level. Of cause, at the oscillation of F_3 , the Landau energy level changes accordingly.

FIG. 7: The Landau levels is chemical potential-dependent for four different magnetic fields. The solid line and dashed lines the energy level of $\eta=1$, and $\eta=-1$, respectively. In Panels A $(eB=0.05~{\rm GeV^2})$, B $(eB=0.10~{\rm GeV^2})$, C $(eB=0.15~{\rm GeV^2})$, and D $(eB=0.20~{\rm GeV^2})$. The red, green, and blue lines denote u, d and s quark respectively.

C. The map of entropy

As a complementary study on the change of quark matter with the rise of temperature and chemical potential, the path for the transition from chiral condensation to tensor condensation also needs to be considered. The, isentropic diagrams have been plotted in Fig.8. The color gradients depict the magnitude of entropy changes, with isentropic lines crossing both chiral and tensor condensation phases. The isentropic line as $S[M_f, F_f, B] = S[\mu, T, B]$ could connect tensor condensate with chiral restoration. In the coexistence of tensor and chiral condensation, F_3 oscillations always exist. Thermodynamic potential differences for different magnetic intensities between the point (T = 60 MeV, $\mu = 470 \text{ MeV}$) and the point (T = 100 MeV, $\mu = 160 \text{ MeV}$) is the transition curve of quark matter from low pressure and high temperature to high pressure and low temperature, and the thermodynamic potential density differences of 1 GeV^3 order.

FIG. 8: The contour maps of the entropy distributions in the T - μ plane. The panels correspond to different magnetic fields: A for $eB = 0.05 \text{ GeV}^2$, B for $eB = 0.10 \text{ GeV}^2$, C for $eB = 0.15 \text{ GeV}^2$, and D for $eB = 0.20 \text{ GeV}^2$.

IV. SUMMARY AND CONCLUSIONS

In this study, we have utilized the (2+1)-flavor NJL model to characterize the four-point interaction and investigated the relationship between chiral and tensor condensation under a strong magnetic field. We have identified the phase boundaries by varying the temperature and chemical potential. Our results indicate that the quark tensor condensate is primarily present in the low-temperature region and tends to diminish in the high-temperature region. Quark matter characterized by tensor condensation displays a magnetic catalytic effect. Additionally, the peak value of the tensor condensate is observed during the chiral restoration, and it gradually decreases as the temperature continues to increase.

In our work, we have taken F_8 from the spin polarization as a measure of ferromagnetism and F_3 as a metric for spin density, which effectively illustrates the variations of the tensor condensate. Especially in the presence of a magnetic field $eB = 0.05 \text{ GeV}^2$, the tensor condensation counteracts the energy loss associated with the dynamical loss of quark mass due to chiral symmetry restoration. Our analysis indicates that the spin polarization exhibits oscillations with the increasing of Landau energy levels.
