Abstract

The monitoring and prediction of in-class student activities is of paramount importance for the comprehension of engagement and the enhancement of pedagogical efficacy. The accurate detection of these activities enables educators to modify their lessons in real time, thereby reducing negative emotional states and enhancing the overall learning experience. To this end, the use of non-intrusive devices, such as inertial measurement units (IMUs) embedded in smartwatches, represents a viable solution. The development of reliable predictive systems has been limited by the lack of large, labeled datasets in education. To bridge this gap, we present a novel dataset for in-class activity detection using affordable IMU sensors. The dataset comprises 19 diverse activities, both instantaneous and continuous, performed by 12 participants in typical classroom scenarios. It includes accelerometer, gyroscope, rotation vector data, and synchronized stereo images, offering a comprehensive resource for developing multimodal algorithms using sensor and visual data. This dataset represents a key step toward scalable solutions for activity recognition in educational settings.

Background & Summary

The ability to estimate the action a human is performing is really useful for a variety of tasks, ranging from healthcare and marketing to monitoring and user interfaces. This task can be carried out using different technologies such as deep learning algorithms and transformer-based architectures. These novel approaches have reportedly very good accuracy but they need vast amounts of labeled data. The data can be sourced from different sensors, for instance color cameras, depth cameras or motion-capture setups. One of the most convenient sensors to gather data to feed human activity prediction systems is the Inertial Measurement Unit (IMU). These sensors are able to measure the velocity and orientation. In addition to that, they are present in the majority of smartphones and smartwatches of the industry. Consequently, if an algorithm is developed to predict a user’s activity based on the internal IMU of a smartwatch, it has the potential to be widely applicable and beneficial for the majority of smartwatch users. With this in mind, we have created CADDI, an in-Class Activity Detection Dataset using IMU data from low-cost sensors. We have captured acceleration and orientation from a regular smartwatch of 12 subjects performing 19 different human actions that can be carried out during a class. The samples were recorded with a closeup stereo color camera, which are also included. The actions considered are continuous (carried out over time), such as resting, drawing or using a keyboard; and instantaneous (happen on a small time frame), such as raising a hand, drinking or turn a page. As stated, the recorded actions are those likely to happen in a classroom.

Several datasets have been developed to predict human actions from IMU data. The most relevant ones include watchHAR [1], which contains inconsistent IMU data from 20 subjects across 16 categories. VIDIMU [2] is more complete, with IMU and image data from 16 subjects in 13 activities, although it uses custom sensors that limit real-world application. PAMAP2 [3] involves 9 subjects performing 12 activities, with some performing up to 18, but does not specify handedness. Capture-24 [4] documents a normal day of participants with broadly defined activities, labeled by the subjects themselves, and includes egocentric images. mHEALTH [5] records 12 physical activities from 10 individuals over a short timeframe. OPPORTUNITY AR [6] and OPPORTUNITY++ [7] simulate daily activities in a sensor-equipped room with 4 individuals; the newer version includes side-view videos and AI-extracted kinematic data. GTOV [8] focuses on calorimetry in older adults, featuring 35 individuals over 60 years old in 16 activities. REALDISP (REAListic sensor DISplacement) [9] investigates sensor displacement effects in activity recognition with 33 categories of physical activity. Finally, HAR [10] includes 6 continuous physical activities performed by 30 participants using smartphone-embedded IMU.

As it can be seen in this review of related works, the most complete datasets are captured with expensive and complex sensors and only depict physical activities like walking, jumping or jogging. Some other datasets that were captured with regular smartphones or smartwatches are either of physical activities as well or incomplete, providing different categories for each individual. In addition to that, most datasets do not include images of the actions. Finally it is worth noting that, there is no dataset that includes IMU data on a classroom environment, and in general, the reviewed datasets focus on activities of daily living and physical exercises.

We focused in the activities carried out in class because it could help to develop algorithms to monitor the activities of students during a lesson. This goal is related to detect stressful, boring or interesting parts so the teachers could be aware in real time and introduce changes in the lessons to reduce negative experiences and improve the engagement in class.

Methods

This section describes the data capture process and the custom setup used to collect data for in-class activity detection. The rig includes a stereo camera, smartwatch, and an a computer. Data from the smartwatch sensors, including accelerometer, gyroscope, and rotation vector, are collected and synchronized with stereo camera images. The protocol differentiates between continuous and instantaneous activities, ensuring accurate and synchronized data collection for a wide range of classroom actions.

Capture Setup

In order to capture the data, a custom capturing rig has been developed. The diagram of such device is shown in Figure 1. Hardware-wise, it comprises four main components: an a computer, a stereo camera, a smartwatch and a router. The camera is connected through USB to the computer. Both computer and smartwatch are connected to the router via WiFi, which is the channel they use to share data.

Specifically, the components of the setup include an i7 processor with 16GB of RAM and a GTX 1650 GPU. This system is capable of running algorithms written in various programming languages and is equipped with WiFi, Bluetooth, wired Ethernet, USB 3.0 ports, and HDMI connections; a ZED, which is a stereo color camera

capable of providing two images of 1080p resolution with a theoretical working rate of 30 Hz; and a Samsung Galaxy Watch 5, which features an accelerometer, gyroscope, and rotation vector, all running at 100Hz. The router is a D-Link DSR-1000AC with WiFi capabilities of up to 1300 Mbps.

The setup, which is shown in Figure 2, also features a regular desk. The camera is placed on a tripod, in front of the user and pointed to them, a laptop, a wireless computer mouse, some pens and pencils, and a notebook or paper sheets. The users also carry their smartphone in their pocket, and a backpack with a bottle by their side placed on the floor. This setup aims to imitate the conditions of an actual student in a classroom. Due to this, the mentioned elements are organized by them with no further restrictions. The only requirement is that the camera is pointed towards them.

Regarding the software, the computer runs a custom program that accesses the stereo camera, directly through its USB connection, and stores the images. In parallel, the program also receives the data packets sent by the smartwatch, that runs a custom android app that gets the IMU data and send them through the WiFi local area connection once per second.

Synchronization

The dataset includes accelerometer data, gyroscope data, orientation data, and images. The accelerometer, gyroscope, and rotation vector records are provided by the smartwatch at a rate of 100MHz and are internally synchronized by the smartwatch itself. Thus, 100 records are obtained at the same time and packed with the same timestamp. The time of the computer is shared with the smartwatch so both are synchronized. The smartwatch time is triflingly delayed by the time it takes to the sync packet to travel from the computer to the smartwatch. The stereo camera is triggered by the computer that queries the images at 25-30 fps. Each pack of two images (left and right of the stereo setup) is labeled with the timestamp of the computer.

The smartwatch does not stream the IMU data in real-time. Instead of that, the records are buffered in blocks of 100 readings in the smartwatch, so only one connection per second is done between the computer and the smartwatch. We do this to alleviate the computing requirements of the system and to avoid flooding the network. Images and IMU data can be easily matched together as both computer and smartwatch are synchronized, and the records labeled with the corresponding timestamp. As expected, not all IMU registers will have a corresponding image due to the difference in the working rates of the sensors.

Procedure

The protocol we followed to record the data is as follows. First, the participants are instructed to sit down and prepare the desk with their laptop, notebook, mouse and pen and pencils. Their smartphone would be on their pocket and the backpack on the floor with the bottle in it. Each individual sets the environment on their own, as if they were in a real classroom. Then, the procedure is different depending on the type of activity. For the continuous activity, the user is instructed to do it for 210 seconds. Only the central **200** seconds are actually stored, so we discard the first and last part of the sequence. Otherwise, if the activity to record is of type instantaneous, the participant is instructed to begin by the technician recording the data. This way, only the data related to the activity is recorded. In this case, each action is repeated 20 times, and takes the required time to perform it. This time may be different for each activity and each instance even within the same category.

As mentioned earlier, there are two types of activities: the continuous activities are those that are performed during an extensive timeframe. For instance, typing on smartphone, writing or drawing on a paper are within this category. On the other hand, the instantaneous activities are those that happen in a very narrowed time span, barely seconds. Raising a hand, drinking or stretching out are within this category. The list of activities considered in the dataset is shown in Table 1. As mentioned earlier, this dataset is intended to collect activities that are carried within a classroom during a regular lecture.

Data Records

In this section, we summarize the dataset, which includes various sensor data and stereo camera images captured during activities performed by participants. The data is organized in JSON format for sensors and PNG for images, with timestamps ensuring synchronization across all files. The dataset structure is designed to support the analysis of both continuous and instantaneous classroom activities.

Dataset Components

The dataset will store stereo camera images, labeled as A and B, along with sensor values captured by the smartwatch in JSON files.

As indicated in Table 2, the sensor data reveals details about various sensors integrated into the system. The **Samsung HR Wakeup Sensor** measures the user’s heart rate at a frequency of one value per second. The **Samsung Linear Acceleration Sensor** measures the device’s linear acceleration in three axes, excluding gravity, with a sampling rate of 100 samples per second. The **LSM6DSO Gyroscope** reports the rate of rotation around its axes at the same sampling rate. The **Samsung Rotation Vector** sensor, with the same sampling rate, provides rotational information in three dimensions. The **OPT3007 Light Sensor** measures environmental light levels, expressing luminosity in lux units.

The provided images have a resolution of 1920 x 1080 pixels, with pairs of images corresponding to left and right cameras in the stereo setup, each labeled with a timestamp. Parameters such as focus, exposure, gain, and white balance are automatically adjusted using built-in Image Signal Processor features. Images are stored in individual PNG files without compression. It is important to note that the dataset’s images are neither rectified nor distorted in any way.

In total, the dataset comprises 472,03 minutes of recording, during which the following total number of samples has been collected:

- Camera A Images: 437.904 images
- Camera B Images: 437.904 images
- Samsung HR None Wakeup Sensor: 31.727 samples
- Samsung Linear Acceleration Sensor: 3.172.700 samples
- LSM6DSO Gyroscope: 3.172.700 samples
- Samsung Rotation Vector: 3.172.700 samples
- OPT3007 Light: 208.157 samples

The frequency of these values collected by the watch in each experiment corresponds to the smartwatch’s maximum data collection capacity. The frequency of the data corresponds to that shown in Table 2.

The dataset was recorded using 12 participants. The Table 3 summarizes the demographic and physical characteristics of the participants, including age, gender, height, weight, and hand laterality. These characteristics may influence the variability in the recorded activities and should be considered when analyzing the data.

Additionally, Figure 4 presents graphs illustrating non-linear dimensionality reduction using t-SNE. This technique enables the visualization of activities performed by each subject, highlighting clustering based on the sensor employed for analysis (Samsung Linear Acceleration, LSM6DSO Gyroscope, or Samsung Rotation Vector).

For discrete activities, each gesture by each subject is represented as a point in a 2D space, with missing values replaced by the mean. Conversely, for continuous activities, each class for each individual is depicted by a single point in the 2D space.

In these graphs, one can observe how certain variables cluster together and how some classes exhibit similarities. For instance, activities such as retrieving an item from a backpack or pocket, or between drawing and writing, show clear clustering.

Moreover, Figure 5 illustrates the evolution of heart rate. For continuous activities, the average heart rate of each subject for each activity has been calculated. For instantaneous activities, due to differences in duration, the data is presented as a percentage of the activity completed.

Organization

The data collected from the SmartWatch is stored in JSON-formatted files, with one JSON file saved for each second of data collection for each user. These JSON files are stored with a title that reflects the hour, minute, second, and millisecond of a second of the data capture on the clock. To obtain the timestamp of each sensor’s data capture moment, you need to examine the `timestamp` key of each record.

The captured images also include a timestamp of the moment of capture, facilitating their association with JSON files by searching within the subfolders of the experiment name.

The JSON structure consists of a key named `num_samples` indicating the number of samples of each sensor, along with a key named `data` containing the values of the watch sensors: **Samsung HR None Wakeup Sensor**, **Samsung Rotation Vector**, **LSM6DSO Gyroscope**, **Samsung Linear Acceleration Sensor**, and **OPT3007 Light**. Each of these sub-keys is a list of dictionaries with the precise time of the sensor measurement and the remaining values taken in that measurement.

Timestamps are displayed in the `HH:MM:SS.ff` format, indicating the time of day when the measurement was taken (UTC+1). The dataset directories are organized hierarchically. Initially, folders are categorized

by experiment type, continuous or instantaneous. In both cases the following levels are subject, followed by experiment. In continuous, within each experiment there are the folders: camera_a, camera_b and sensors. In the instantaneous experiments, an additional level indicates the gesture number, with each gesture folder containing camera_a, camera_b, and sensors subfolders. The directory structure can be visualized in Figure 3.

1. **CameraA:** Directory containing the image files of the left part of the stereo camera.
Path: /type/subject/experiment/(gesture)/camera_a/
2. **CameraB:** Directory containing the image files of the right part of the stereo camera.
Path: /type/subject/experiment/(gesture)/camera_b/
3. **Sensors:** Directory containing the sensors data in JSON files.
Path: /type/subject/experiment/(gesture)/sensors/

The data files (both dictionaries and PNG images) follow a naming convention based on the time of day when the image was captured or the biometric data was saved in format HH_MM_SS_ff. The experiment names correspond to those shown in Table 1, adapted to snake case writing.

Technical Validation

This dataset was validated using a deep learning model to classify activities. Data were segmented and split into training and validation sets to simulate performance on new users. The model showed higher accuracy for instantaneous actions, providing a useful baseline for future work with this dataset.

Benchmark

To validate the IMU data, a deep learning model was trained to classify the 19 classes in the dataset. The input for the model was created by splitting the complete sequences into fixed-size segments using a sliding window approach [11]. The dataset was divided into training and validation sets by assigning a portion of the participants to each, ensuring that the model never sees any validation data during training. This also makes the results comparable to how the model would perform on entirely new users.

Out of the 12 participants in the dataset, 9 were used for training and 2 for validation. The data was segmented into 2-second windows with a 1-second overlap. The model architecture includes a 1D convolutional layer to extract local features and reduce dimensionality, followed by two LSTM layers to analyze the sequential data, and a dense layer for classification.

Using this model, a validation accuracy of around 65% was achieved. Figure 6 shows the confusion matrix, which highlights that the model performs better on instantaneous actions, achieving an average accuracy of 77%, compared to continuous actions, where the average accuracy is 45%.

Usage Notes

This dataset is designed to facilitate the analysis of in-class activities using IMU data from low-cost sensors. Researchers can utilize this dataset for developing and testing algorithms that detect and predict student activities in a classroom setting. The following notes provide guidelines to aid in the effective reuse of the data:

- **Software and Tools:**
 - Recommended software packages for analyzing the IMU data include Python libraries such as `numpy`, `pandas`, and `scikit-learn` for data manipulation and machine learning, as well as `tensorflow` or `pytorch` for deep learning models.
 - Visualization of the data can be performed using `matplotlib` and `seaborn`.
- **Integration with Other Datasets:**
 - To compare or integrate this dataset with other similar datasets, ensure that the data formats and labeling conventions are aligned.
 - Researchers can use common benchmarks and metrics for activity recognition to evaluate the performance of their models across different datasets.
- **Privacy and Data Access:**

- This dataset does not contain personally identifiable information, except for the recorded faces, thus minimizing privacy concerns. However, any further distribution of the dataset must comply with relevant data protection regulations. All participants have given their consent for the publication of the dataset.

- **Code Availability:**

- Example code for preprocessing is provided in code availability . Researchers are encouraged to build upon these examples to suit their specific needs.
- Additional data-processing workflows or scripts can be made available upon request.

By following these guidelines, researchers can maximize the utility of the dataset and contribute to the advancement of activity recognition technologies in educational settings.

Code Availability

In this section, we provide details on the accessibility and code used to process the data. The code can be accessed through the following link: [CADDI: An In-class Activity Detection Dataset Using IMU Data](#).

The provided code generates a DataFrame where each entry contains information about a complete sequence of an experiment, i.e., data recorded sequentially. For continuous data, each experiment is contained in a single entry, and for instantaneous data, each entry contains information from a repetition of an experiment. An entry in the dataset consists of the following parts:

- **Type:** Type of experiment, continuous or instantaneous.
- **Subject:** The subject performing the action.
- **Action:** Action performed in the experiment.
- **Gesture:** Indicator of the experiment repetition number.
- **Path_Camera_A:** Path to the left camera data.
- **Path_Camera_B:** Path to the right camera data.
- **Path_Sensors:** Path to the sensor files in JSON format.
- **Camera_A:** List of names of the left camera photos.
- **Camera_B:** List of names of the right camera photos.
- **Sensors:** List of names of the sensor files in JSON format.

Along with the code that generates the DataFrame, two functions are added to process the content of a JSON file.

The first function, given the path of a JSON, reads and generates a DataFrame with the information from the file. This DataFrame contains 100 entries, one for each time inertial sensors capture information per second (100 Hz). Each entry contains precise timing information when the sensor data was captured and the values in X, Y, and Z coordinates for the accelerometer and gyroscope, and a quaternion X, Y, Z, and W for the rotation vector (`Acc_Time`, `Acc_X`, `Acc_Y`, `Acc_Z`, `Gyro_Time`, `Gyro_X`, `Gyro_Y`, `Gyro_Z`, `Rot_Time`, `Rot_X`, `Rot_Y`, `Rot_Z`, `Rot_W`). In Figure 7, the orientation of each axis on the smartwatch can be observed.

The second function generates a *numpy array* of shape (100, 10), where the first dimension corresponds to the values taken in one second and the second to the sensor values excluding the time stamps (100 values * `Acc_X`, `Acc_Y`, `Acc_Z`, `Gyro_X`, `Gyro_Y`, `Gyro_Z`, `Rot_X`, `Rot_Y`, `Rot_Z`, `Rot_W`). A version of this function analyzes all JSON files from a directory and generates an array of shape (X , 100, 10) where X is the number of files in the directory.

Additionally, a function is included that enables visualization of the contents of a DataFrame entry. This function displays the sequence of images from Camera A alongside a diagram with accelerometer data. The visualization helps in understanding the sequence and dynamics of the experiment based on the captured sensor and image data. An example of how the viewer works can be seen in Figure 8
